# STABILITY

BEHIND a truck investment, as behind a financial investment, you need STABILITY of value most of all. Without it you have no investment. Without it your purchase is an uncertainty. The White Truck has many different values in and behind it, but they all can be summarized in the one word STABILITY.

***Stability of the Maker:*** The White Company is the foremost truck maker in this country, solidly built up and steadily expanded, with resources and an organization which make for continued leadership in the industry.

***Stability of Policy:*** Since the first White was built, the company has never deviated a hair's breadth from a fixed policy: to build trucks that will do the most work for the least money.

***Stability of Product:*** White Trucks have stood up and kept going day after day, year after year, in all kinds of service and under all sorts of operating conditions. There are a few records of 500,000 miles; a number of 300,000 miles; more of 200,000 miles and many of 100,000 miles, with the trucks still in daily service.

***Stability of Quality:*** Regardless of the cost of material, the quality of White Trucks has been unvaryingly high grade.

***Stability of Price:*** During the past five years White prices have increased a mere fraction of the average advance in truck prices. Expanded output and steadily improved manufacturing efficiency have stabilized both quality and price in the face of increased costs of labor and material.

***Stability of Ownership:*** The Annual Roll Call of White Fleets in actual service, listing owners of ten or more Whites, has no parallel in the truck industry. It is graphic proof of the most remarkable truck ownership in America; as remarkable for the quality of the ownership as for its extent and steady growth from year to year. The Roll Call contains the names of three hundred and fifty concerns with a total of 12,674 Whites. All together there are 3,691 White Fleets comprising 40,919 trucks, exclusive of single-truck installations.

***Stability of Service to Owners:*** White Service facilities have been built up step by step to keep pace with an expanding distribution of White Trucks. This growth has required years of development, and an investment of millions.

***White Trucks are an Investment*** of recognized earning power, backed by a responsible truck manufacturer with years of successful experience, thousands of trained employees, tens of thousands of trucks in active service, adequate capital and a nation-wide service organization.

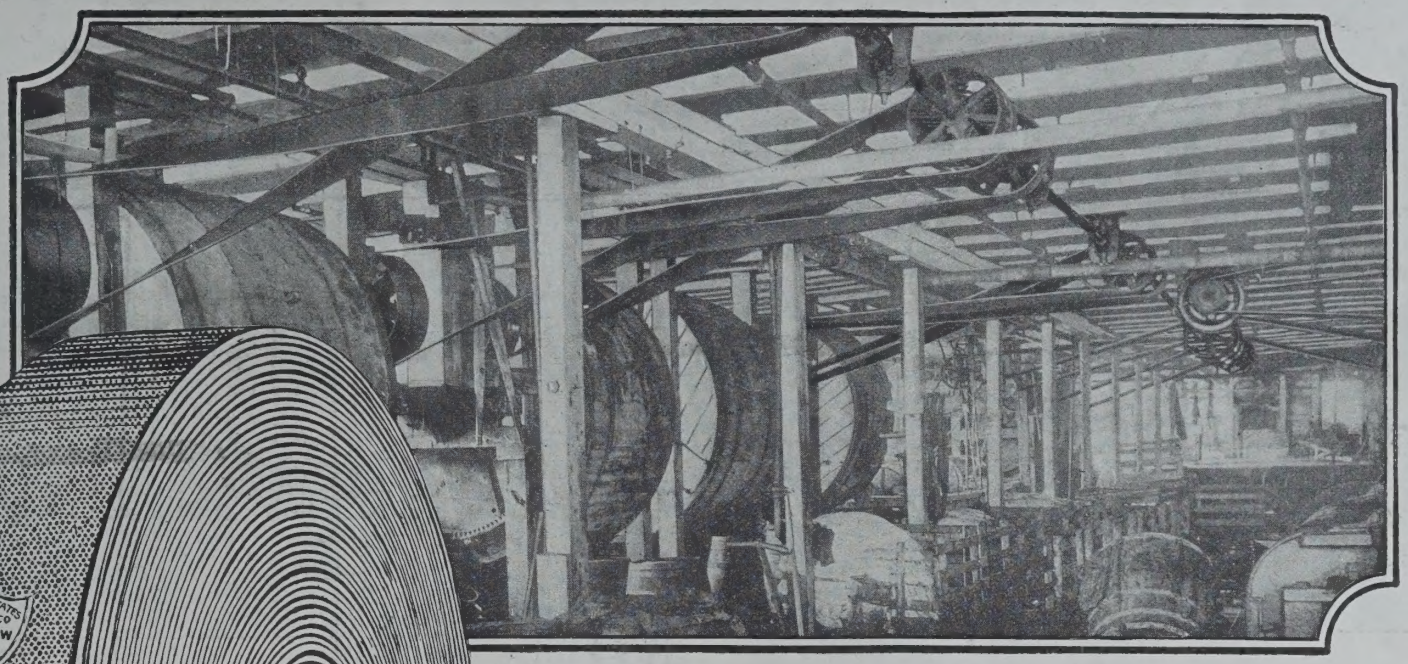
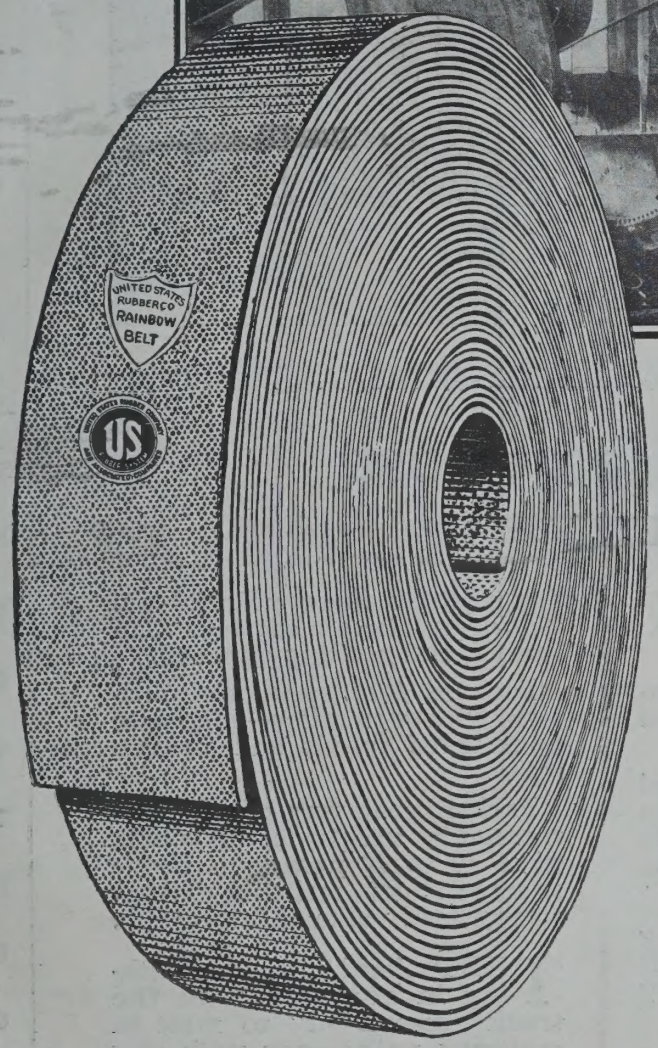
## FRICTION SURFACE BELTING





## Tanneries are Adopting Rubber Belting

This tannery beam room is equipped throughout with *Rainbow Friction Surface Rubber Belts.* The loads are heavy and intermittent—the speeds slow, 1500 to 3000 feet per minute—the place damp and sloppy. There is a shifter on each machine.

Two years' trial—not snap judgment, not a tempting price nor a salesman's argument—was the determining consideration. Performance under the most trying conditions of belt service won preference for *Rainbow Belts.*

If you have a belting problem, put it up to our representatives and engineers. They will study it and make complete recommendation, covering the style, ply and size to give lowest belt costs per year.

*Feeding a great city with the aid of the Motor Truck. Though only nine years old, this Packard Truck has seen several generations of ordinary trucks go to the scrap heap. There are many Packards still doing today the same work they started to do nearly fourteen years ago*

# What Does the Scrap Heap Cost American Business

OFFICIAL survey shows that American business put $408,311,585 into motor trucks last year, and will spend another $568,650,000 during 1920.

How much of this vast expenditure represents *net growth* in trucking facilities?

How much is simply *replacement* of trucks bought only two or three years ago?

You can get out of a truck just what the builders put into it—and *no more.*

THE Packard people are primarily *transportation engineers.*

The basis of the Packard Truck is *unified engineering*—not merely a blue print and specifications of commercial parts; but Packard engineering design and Packard control of every Packard part.

Packard frames of *rolled* channel steel—not commercial pressed steel.

Packard live axles of special steel, *heat-treated* in furnaces designed by Packard. Tensile strength—220,000 pounds to the square inch.

Packard Engine both *strong* and *simple.* Four crank shaft bearings, as against the ordinary three.

*One* cam shaft only, and but *three* timing gears, in the Packard.

All valves *enclosed*, with automatic lubrication.

Packard clutch and universal joints *enclosed.* The clutch of dry multiple disc type, with *extra-large* clutch surfaces. No leather, and nothing exposed.

Packard *four-speed* transmission, with *even* ratios—as against only three speeds and uneven ratios.

Packard gears *forged* and *heat-treated* by *unique* methods that give 10 to 20 per cent. above average shock resisting ability, steady load value and long life.

THE Packard Truck has nothing in common with the truck "assembled" to meet an arbitrary price—nor with that built on the "exclusive" one-at-a-time idea.

It is built and sold on the business-like basis of *assured transportation returns* every day—an enduring *net gain* in your trucking facilities.

For each section of the country the diagrams refer the output of other petroleum products to that of kerosene, showing how many gallons of the other liquid fractions are obtained for every gallon of kerosene recovered

**How petroleum constitution and petroleum treatment vary from State to State**

## Where the Petroleum Goes

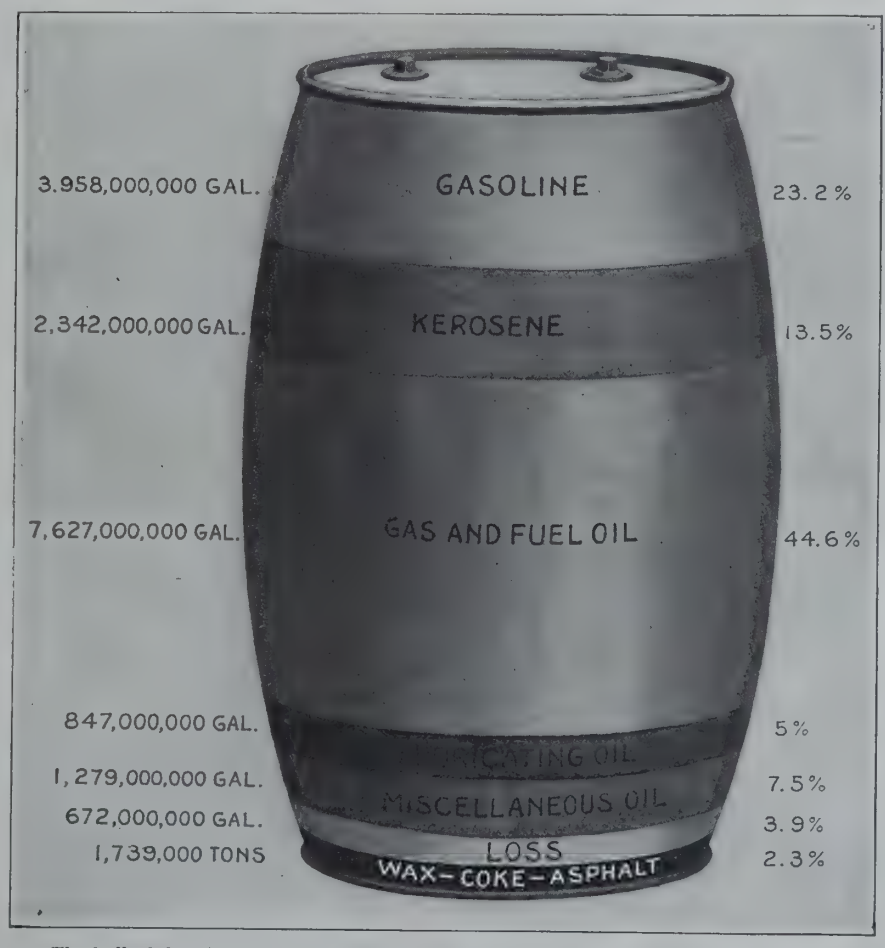
**By J. Malcolm Bird**

SOME weeks ago we discussed the gasoline situation from the viewpoint of sources of supply, showing as well as we could just where the petroleum comes from. But we pointed out in that article that gasoline is only one of the products of the petroleum refinery; it is therefore in order to ask and answer the further question "Where does the petroleum go?"

Individual refiners hesitate to answer this question. A given refinery deals with petroleum from a single section of the country, and employs a given process of extraction which is determined in part at least by the immediate market within easy shipping distance of the refinery. Thus one refinery may run heavily toward the recovery of one fraction, sacrificing others to this one; while another establishment may exactly reverse this choice. For it is to be emphasized that the refining of petroleum is not the sort of process that leads to a unique and inevitable result, like the sorting out of tall and short persons from a crowd. Within very wide limits, what we get out of our crude oil depends upon what we do to it; even more it depends upon the grade of the oil—another variable with very wide limits of its own. So when you ask the owner of one refinery or even of one large group of refineries to estimate what the United States makes out of its petroleum each year, he will throw up his hands and explain that the most he can do is to tell you what he makes out of *his* petroleum, and that he does not want to do that for fear that you will make the very mistake of supposing this to represent some sort of rough general average for the entire country.

The Bureau of Mines, however, presents figures which show the aggregate bulk of petroleum treated in the United States for each year, and the aggregate of each product recovered. These figures automatically represent American practise as a whole, and it is to them that we turn for the material for the present discussion. The first thing that they tell us is that the refiner was not "spoofing" us when he pleaded that his showing meant nothing for the country at large. For instance, the refineries of the east coast get only 11 per cent more gasoline than they do of kerosene out of their crudes. But for the Colorado and Wyoming refineries, the gasoline extraction exceeds that of kerosene by no less than 261 per cent. And the other sections into which the petroleum industry divides the country make showings that fall at various levels between these two extremes. So there is no joke at all about the statement that crude oils differ, and that the only way to see what a given oil will yield is to try it out.

**For the United States as a whole, gasoline, fuel-oil and lubricating-oil production compare with kerosene output as here indicated**



The bulk (left) of each major fraction; and the percentage (right) by volume which it constitutes of all petroleum treated

**Where Uncle Sam's petroleum goes**

The kerosene fraction is taken as the standard of comparison here and in the drawing that elaborates upon this aspect of the situation merely because it is the fraction most closely bound up with the history of the industry, and because at the same time it comes about as close to being present in constant proportion as any other constituent—though this approach to uniformity is by no means a narrow one. Referring the three other principal products to kerosene in this way, we see that for the entire country we extract 1.69 gallons of gasoline for each gallon of kerosene that the crude oil yields—the sectional showings, as we have just seen, varying from 1.11 gallons for the Atlantic Coast to 3.61 gallons for the Colorado-Wyoming field. For the fuel-oil and gas-oil group, the general performance is 3.26 gallons for each gallon of kerosene; Pennsylvania petroleum is the leanest in these fractions, yielding only .88 gallon for each gallon of kerosene, while California makes the prodigious showing of 11.28 gallons of the heavy oils to one of kerosene. American crudes as a whole yield .36 gallon of lubricating oil for each gallon of kerosene; the Colorado-Wyoming field with .05 gallon and the Pennsylvania refineries with .95 gallon representing the extremes. So it is quite obvious that we can make no generalization as to the per cent of gasoline, kerosene, etc., in petroleum; all we can say is that petroleum contains these constituents, in proportions that must be determined in each individual case.

If we cannot make any generalization with regard to the constitution of petroleum, however, we can safely assume that the grand total of the American output of crudes is substantially the same from one year to the next. Over a period of years this would not be a safe supposition, since one field gets worked out and new ones are opened up; but from one year to the next, the percentage of hydrocarbons that will distil over up to a given tempera-

## Railroads the Foundation of National Prosperity

ASK the average man what is the material asset upon which the prosperity of the United States is founded and he will doubtless mention agriculture. Theoretically, he would be right. Modern civilization, however, particularly the mechanical side of it, has so greatly modified conditions that it may well be questioned whether in the United States, with its vast distances, the railroads do not take equal rank with agriculture as the foundation upon which our industrial and financial well-being is built up.

In the earliest times, as today, subsistence and wealth came out of the soil; but life in those days was very much a hand-to-mouth matter, and it was only as civilization developed that consumption of the fruits of the earth, whether in food or materials, took place at any distance from the source. This development has progressed to the point where the local consumption is absolutely insignificant, and practically the whole of the fruitage of the earth, whether in wheat, coal, oil, metals or what not, is carried to the four corners of the earth for consumption. Particularly is this true of the United States; and it is no exaggeration to say that our great railroad systems are not merely the foundation of our national prosperity, but are inextricably interwoven with the whole fabric of our daily life.

How closely the prosperity of the railroads is related to the prosperity of our great industries was forcibly brought home to the editor during a recent extended trip through the Middle West and the Northeastern states. In establishment after establishment we heard a story which ran somewhat as follows: "We are overloaded with orders. We have all the labor we require, and in the main it is contented and satisfactory. But our operations are limited by the scarcity of cars and the general let-down of transportation. We are able neither to obtain the necessary raw materials nor to ship the finished product." Evidence of the literal truth of these statements was to be seen in the general depletion of stockyards at one end of a works and in the congestion of finished products awaiting shipment at the other end.

So far as legislation is concerned, the most effective plan for the Government to follow in assisting to bring back normal conditions would be immediately to give every possible assistance to the railroads in making good the serious shortage of locomotives, cars and general equipment. Above all, effort should be made to build, with all possible speed the greatly needed freight cars. Until the shortage has been relieved, we may try every possible means to bring back normal conditions without avail. The cry for increased production is futile, since the railroads are not able to handle even the present output.

An analysis of the condition of our railroads, which we published in January, showed that under normal operation they require about 2,000,000 tons of steel rails per year, whereas in two years, the Railroad Administration had purchased directly only 200,000 tons of steel rails. Annually, the railways require about 100,000,000 new ties, but apparently, under Federal control there will be a shortage of about 25 per cent, or say 50,000,000 ties. During the four years prior to Federal control, the railways built an average of 100,000 freight cars per year, whereas the Administration had purchased only 100,000 freight cars in two years of which only 90 per cent had been delivered. Moreover, during the past two years, freight equipment had not been maintained in normal condition. It is estimated that about 200,000 new cars must be built in 1920 to make good the deficiency. The same story of shortage had to be told with regard to locomotives. The normal requirements are about 3,000 new locomotives per year. Yet during Federal control, only 2,000 locomotives, or one-third of the normal requirement have been provided.

It is one of the marked futilities of human nature that it is ever prone to give its attention to the things remote, and overlook those which are pressing for attention close at hand. Truly, a prophet is not without honor save in his own country—and amid the thousand and one nostrums that have been shouted at the dear people in the effort to get matters straightened out, we are hearing far too little about the one outstanding and supremely important question of the era—namely the rehabilitation of our great railroad systems.

## The Scientific Value of Speed Contests

IN all great sporting contests in which high speed is the deciding factor, many people, in whom the critical faculty is developed at the expense of others equally valuable, make themselves audible in protest against the sacrifice of strength and durability which is necessary in producing a first-class racing machine, be it airplane, yacht or automobile. "What is the sense," they ask, "of building a contraption which, if it should be so fortunate as to hold together for one supreme effort, has no further use in the broad field of sport and pleasure?"

An off-hand answer to this question would be to remind these gentlemen that sport is sport; that the craving for high speed is a protest against the natural inertia of things; and that, if a man does not possess in his veins the good, red blood to which speed as an element of sport appeals, it is more his misfortune than his fault, and he is to be pitied rather than blamed. But, as a matter of fact, the ardent pursuit of speed in racing machines has reacted most favorably upon the mechanical arts. The race course is a very practical, man-sized kind of laboratory, where the products of the labor of the designer at his drafting board are given a gruelling test, during which the one weak link in the chain, if there be such, is certain to be disclosed. The great value of the construction and competition of racing machines is that we gain in knowledge of the dynamic as compared with the static stresses. Static stresses can be determined with great accuracy, and the testing machine gives us equal accuracy in determining the strength of materials; but in driving an automobile at a racing speed, and even more in smashing one's way with an oversparred and lightly-constructed yacht against short, snappy seas, there are dynamic stresses developed, the exact strength and effect of which no man can foretell through the medium of theoretical calculations.

Moreover, racing has greatly stimulated the quest for materials that are light in proportion to their weight; and there can be no doubt that for the many wonderful alloys which are available in the constructive arts today we are beholden, not a little, to the craze for speed, with its demand for a maximum of strength with a minimum of weight. To think of the racing car is to think of aluminum, vanadium steel, and last, the wonderful molybdenum steel; and a retrospective survey of the America's Cup races calls to mind the hollow steel boom of "Valkyrie III," the Tobin bronze and aluminum hull of "Defender," the light but strong hollow wooden spars culminating in the great hollow mast of "Shamrock IV," and the tapered, hollow aviation spar which forms the topmast of "Vanitie," to say nothing of the aluminum gaff carried by "Resolute." A test case as to the industrial value of yacht construction is the three-ply mahogany shell of "Shamrock's" hull, which proved so tough and strong and water-tight that its designer built Government ships, during the war, of a thousand tons capacity, on this principle.

And to get away from man-made machinery, who shall measure the enormous benefit conferred by the centuries of effort to produce the thorough-bred race horse of today? So valuable has been this effort of man to coöperate with nature, that the last word of praise which we can give to a horse is to speak of the thorough-bred strain that runs in its blood.

## A Problem of Freight Distribution

IN a recent issue we referred to the proposed solution of the problem of freight distribution on Manhattan Island which contemplates the bridging or tunneling, or both, of the Hudson River for the purpose of bringing standard freight cars to the northern part of Manhattan Island and distributing them to warehouses and steamships by means of an elevated marginal railroad extending along the Hudson River waterfront. With such terminal facilities it would be possible for a freight car that was loaded at New Orleans, St. Louis, Chicago or San Francisco, to pass directly to a storage warehouse or a steamship on Manhattan without breaking bulk.

There is another scheme of distribution which involves a principle which has been receiving increasing recognition since the introduction of motor trucks, and which we believe is destined to be a powerful factor in solving the future problems of freight handling and distribution in such congested centers as Manhattan. We have in mind a plan which is sponsored by Colonel W. J. Wilgus, former Chief Engineer and Vice President of the New York Central Railroad Company, which contemplates the construction of a special system of small electrically-operated subways, similar to one already in existence and operating successfully at Chicago, for the delivery of freight directly to the basement floor of the consignee. Reference was made to this system in a paper read by Colonel Wilgus at a recent meeting of the New York section of the American Society of Civil Engineers, which is published in full in the July issue of the SCIENTIFIC AMERICAN MONTHLY. Colonel Wilgus disapproves of the plan for bringing the full-sized freight cars of the railroads onto Manhattan Island. He believes that inasmuch as somewhere in the metropolitan district there must be a transshipment of Manhattan freight from the standard railroad car to a distributing vehicle, it should not be done on costly property and among congested surroundings located as near as possible to Broadway. He believes it would be more economical and convenient to effect this distribution at the western road terminals on the New Jersey meadows, carrying the freight thus distributed to Manhattan by tunnel in trains of electrically-operated, small-unit vehicles. Distribution would be by way of small subways located near the surface, which would deliver these cars direct at, or into, the basements of the warehouses and manufacturing establishments of the consignees on Manhattan. Where delivery was not made direct by these electric freight trains, the containers holding the freight would be removed from the cars and placed on motor truck chassis for short radius "store-door" delivery. This principle of using standardized freight containers, which can be mechanically lifted from railway trucks and placed upon motor chassis, is already in successful operation in several localities, and there is no doubt that its extended application will prove to be highly economical in reducing labor costs.

The plan of bringing the full-sized railway freight cars by bridge or tunnel to a marginal railway on Manhattan is not antagonistic to the scheme of Colonel Wilgus for classifying freight in Jersey City for distribution by means of small electrically-operated freight subways. The one system would be complementary to the other, and there is room for both.

We have touched upon but one point only of this paper, which deals with the whole railway situation in its relation to the all-important question of pier accommodation. The author believes that every effort should be made to have the Dock Department enlarge the width and increase the rail and mechanical facilities of the 125-foot piers that are proposed at Staten Island. We commend the paper for careful reading, as being a complete summary of the transportation problem as affecting the interests of the leading seaport of this country.

## Engineering

**Hydro-Electric Possibilities in Transcaucasia.**—The next few years will witness a great development in the utilization of potential water power for electrical purposes in Transcaucasia. The mountainous character of the country and the proved mineral wealth are the two important factors that will make these undertakings commercially profitable. The total existing hydro-electric stations yield only 6,725 horse-power, although surveys have indicated that over 350,000 horse-power is possible.

**American Locomotives for Portuguese East Africa.**—The Lourenco Marques Railway has recently received eight American locomotives, five of the Santa Fe type and three of the Pacific type, and they have proved far superior to any of the foreign engines in use, according to a U. S. Consular report. The Lourenco Marques Railway connects the port of Lourenco Marques with the railway system of South Africa and is the most convenient route for imports into the region of which Johannesburg is the center.

**Rail-Creep on Railroad Bridges.**—The chief engineer of the Madras Railway has something to say regarding rail-creep on railway bridges in India, in a recent issue of *Indian Engineering*. In the case of the Godaveri bridge, where the creep amounted to as much as three to four feet a year, a special cast-iron sleeper was designed to suit the 75-pound flat-footed rail, with a jaw large enough to receive a lock-fast steel key. This reduced the creep to insignificance, and generally the author is confirmed in the conclusion reached by him in 1887 that "creep" can only be remedied by effective anchorage.

**Lumber Conservation.**—At last we Americans are thoroughly aroused over the seriousness of our lumber resources. For decades we have been cutting down our splendid forests with little thought of reforestation; for the past ten years a mighty host of periodicals and newspapers have been clamoring for thousands upon thousands of tons of paper each week, which has meant the cutting down of thousands of acres of splendid timber. With the advent of the great war, more forests were cut down to build the expansive cantonments, wooden ships, and other things. And now we are confronted with seriously depleted forests. Reformation and conservation are the subjects of the hour, for wood is something without which we can hardly get along. Other countries, not favored with the abundant forests which we have had in the recent past, have long exercised good judgment and care and reforestation in guarding their timber reserves. France, for instance, practises the greatest economy in the use of lumber. Most French farmers get along with the identical buildings of their great grandfathers. The annual consumption in France is not more than one hundred board-feet per capita, or less than one-third the quantity used by Americans.

**Consistency of Concrete.**—In an article appearing in a recent issue of the *Canadian Engineer*, H. E. Davis has much to say about concrete road construction. Among other things he deals with a simple method of checking the consistency or flowability of concrete so as to keep the water content of the mixture fairly constant. The question of correct consistency is, in most instances, treated with the proportioning of aggregates, as this combination results in the best concrete. Most engineers prefer dealing with the question of consistency first and allowing the question of proportion to be dealt with afterwards. A scheme that was used on certain work proved to be of great value in keeping the consistency constant. The method was to place a shovelful of green concrete at one end of an inclined board and note whether it would flow when the board was at the angle at which concrete of the best consistency should flow as predetermined by laboratory investigation. After heavy rains, stock piles absorb a considerable quantity of water, but with the scheme mentioned above it is quite easy to keep the same consistency throughout the work. It requires very little time to determine the right angle and the method has the advantage of keeping the water content of the mixture fairly constant and assists in placing and finishing.

## Science

**Endowment of the National Research Council.**—It is announced that the Carnegie Corporation of New York will place a fund of $5,000,000 in the hands of the National Academy of Sciences to be used as a permanent endowment of the National Research Council and to provide a building in Washington which will house both the Council and the Academy.

**A Scientific Conference on the Pacific.**—The Committee on Pacific Exploration of the National Research Council is planning the program of a scientic conference to be held at Honolulu next August, under the auspices of the Pan-Pacific Union, at which it is proposed to outline some of the fundamental scientific problems of the Pacific Ocean region and to formulate methods for their solution.

**Professor Pier Andrea Saccardo,** who recently died, was born at Treviso, Italy, in 1845, and during the greater part of his professional life was director of the Royal Botanic Garden of Padua. Saccardo's name is a household word among botanists all over the world, chiefly on account of his great work on the fungi, the Sylloge Fungorum, which has been in course of publication since 1882, the twenty-second volume having been published in 1913. Prof. Saccardo was, however, the author of much other important literature relating to mycology and other branches of botany.

**The Amundsen Expedition.**—According to *La Géographie*, the Norwegian Government has sent out a supporting expedition for Roald Amundsen's transpolar voyage. This supporting party, which is led by Lieut. G. Hansen, of the Danish Navy, who was with Amundsen in the voyage of the "Gjoa" in 1903-5, spent the past winter at Etah, in northern Greenland, and expected to leave in March with a dozen sledges for Cape Columbia. Amundsen planned to leave his ship, the "Maud," at the most northerly point attained in its drift, and travel over the ice to Cape Columbia, where he is likely to arrive in March of next year.

**Scientific Workers and the Income Tax.**—In Great Britain, where the income tax is an even more serious burden upon inadequately paid scientific workers than in this country, a committee representing the British Association of Chemists, the Institute of Chemistry, and the National Union of Scientific Workers is circulating a petition which will be presented to the Treasury, in favor of deducting various expenses incurred in scientific work from the amount of income on which the tax is computed. These expenses include subscriptions to scientific and technical societies and periodicals, purchase and renewal of apparatus and materials used in scientific work, rent and expenses of laboratories, etc., expenses incurred in attending scientific meetings, provision of special clothing for work and renewal of clothes damaged in the course of employment, and various other analogous professional expenses.

**Effects of a Reservoir on Rainfall.**—The U. S. Weather Bureau was recently asked by a foreign government for an opinion as to whether it would be worth while to construct a large reservoir for the purpose of increasing the rainfall in a subtropical arid region. Although such questions have often been considered before, the Bureau in this case made a study of the meteorological records of regions of the United States adjacent to large inland bodies of water. The cases considered were the creation of the Salton Sea, in California; the building of dams and the reservoirs formed thereby in Minnesota; and, finally, the probable influence of the Great Lakes on the precipitation of the Lake region. The rainfall records of Arizona show more rain, on an average, since the Salton Sea was formed, in 1906, than before, with the exception of the dry year 1910. The data are not, however, strictly homogeneous, on account of the increase in the number of reporting stations. Furthermore, the proximity of the Gulf of California, a body of water vastly larger than the Salton Sea, seems to vitiate the argument that the presence of Salton Sea has materially affected the rainfall of the region. In the case of Minnesota, the yearly averages for a period of 32 years do not show any progressive increase in the rainfall of the state. A consideration of the probable effect of the Great Lakes led to the conclusion that 2 or 3 inches of the annual rainfall might reasonably be ascribed to the moisture supplied by the Lakes.

## Astronomy

**Another Nova in the Andromeda Nebula.**—The seventeenth nova found in the Andromeda nebula is reported by Milton Humason in the *Publications* of the Astronomical Society of the Pacific, No. 185. It appears on plates taken at Mount Wilson last October, but is invisible in earlier and later plates. It is nearer the center of the nebula than any nova found in that area since the discovery of No. 1 in 1885 and in recorded maximum brightness exceeds all but No. 1.

**Solar Activity in 1919.**—According to a summary of this subject published in the *Monthly Notices*, R.A.S., it is now evident that the maximum of sunspot activity was reached in 1917. The lower average latitude of spots during 1919 and the decrease, both in the mean daily spotted area and in the size of individual groups, is strong evidence that the maximum has been passed. The year 1919 was, however, a period of great solar activity. The month of greatest spotted area was June, though on some days during March, May and August the maximum area of about 2,500 millionths was reached.

**Another Nova in Sagittarius.**—The systematic search that is being made for new stars on the Harvard photographic plates has yielded numerous discoveries, of which one announced March 10, 1920, is typical. A Harvard College Observatory bulletin says: "A new star, making the sixth in constellation Sagittarius, has been found by Miss Woods. The nova is not seen on a plate taken on July 24, 1905, which shows stars of about the twelfth magnitude, but appears on a plate taken on July 26, 1905, of mag. 8.8, and on July 27, of mag. 7.1. It is seen on ten plates taken in August of that year, but decreased rapidly in brightness until August 22, when it was mag. 10.0. It is not visible on recent plates. No spectrum of the star was obtained."

**Some Facts about Satellites.**—From an interesting summary of knowledge concerning the satellites of the solar system, by Dr. S. B. Nicholson, we glean several facts which are perhaps unfamiliar to many students of astronomy. The writer points out, for example, that, on account of our nearness to the sun, the moon is by far the brightest satellite, as seen from the surface of its primary, Jupiter's satellites are large (two of them are larger than Mercury) and some of them are quite near the planet, but their total light on Jupiter, even if all were in full phase at once, would be only one-third that of full moonlight on the earth. The outer satellites of Jupiter are so far from their primary that the perturbative action of the sun is very large; in fact, it may be shown that if it were not for their retrograde motions, Jupiter VIII and IX could not be permanently held by the planet. Perturbations change their orbits so much that it is almost impossible to think of them as orbits, in the ordinary sense. For instance, the eccentricity of Jupiter VIII had been known to change from 0.50 to 0.23 during two revolutions of the satellite. It is quite possible that Saturn and Jupiter have undiscovered remote satellites fainter than the 16th magnitude.

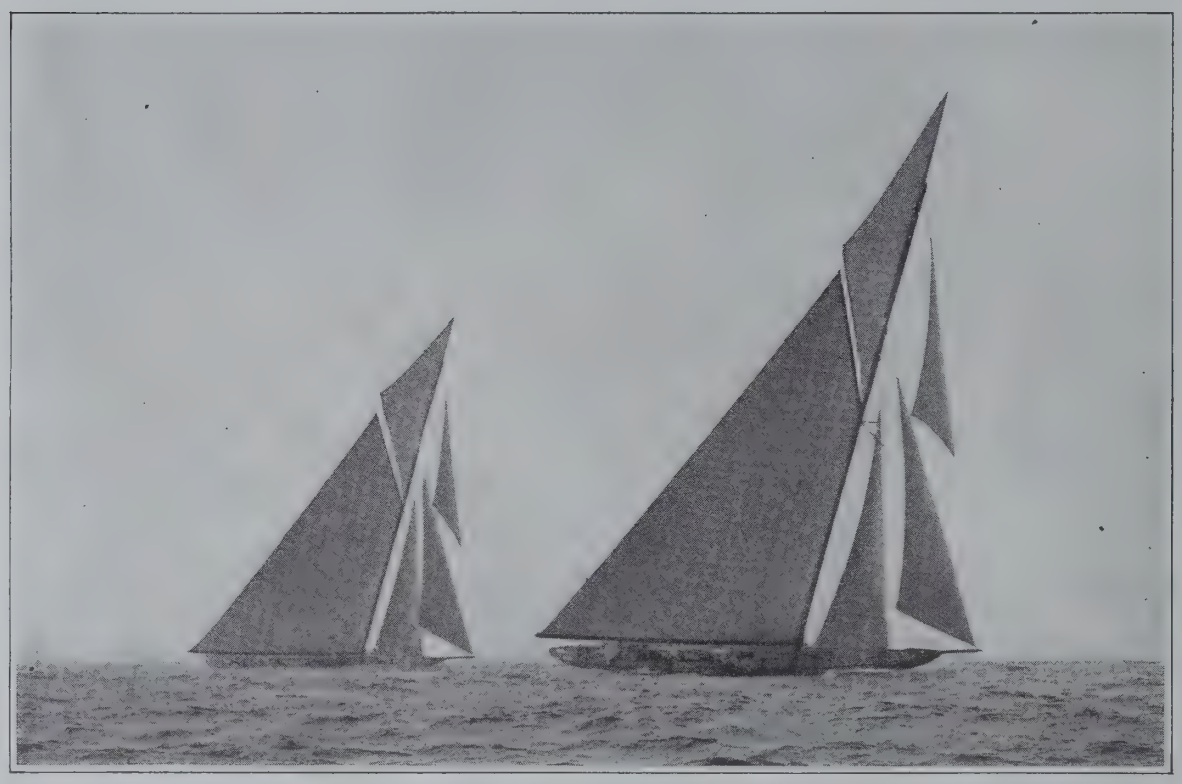
**New Method of Measuring Double Stars.**—Experiments have recently been made by Messrs. Pease and Anderson, of the Mt. Wilson observatory, in the application of Michelson's interferometer method to the measurement of close double stars. An apparatus was constructed with movable slits about 4.5 mm. wide and 25 mm. long, and this was installed about 117 cm. inside the Cassegrain focus of the 100-inch telescope. The diameter of the cone of light at this point being about 73 mm., the arrangement was such that the slits could be separated by this amount. The apparatus carrying the slits could be rotated about the optical axis of the telescope, for determination of position angle. The fringes of stars were observed through an eyepiece of 1 cm. equivalent focus. Much higher magnification is, however, desirable. The investigators report that the resolving power of the telescope for double stars is at least doubled by this method; that good "seeing" does not appear to be important, as the fringes were very sharp under poor atmospheric conditions; that very small angular separations can be measured with an accuracy at least as great as that for larger angles; and that the position angle can be determined as accurately for very close doubles as for those widely separated.

# Tuning Up for the Cup Races

## "Shamrock IV"—The Unknown Quantity Among Four 75-Foot Racing Yachts

By J. Bernard Walker

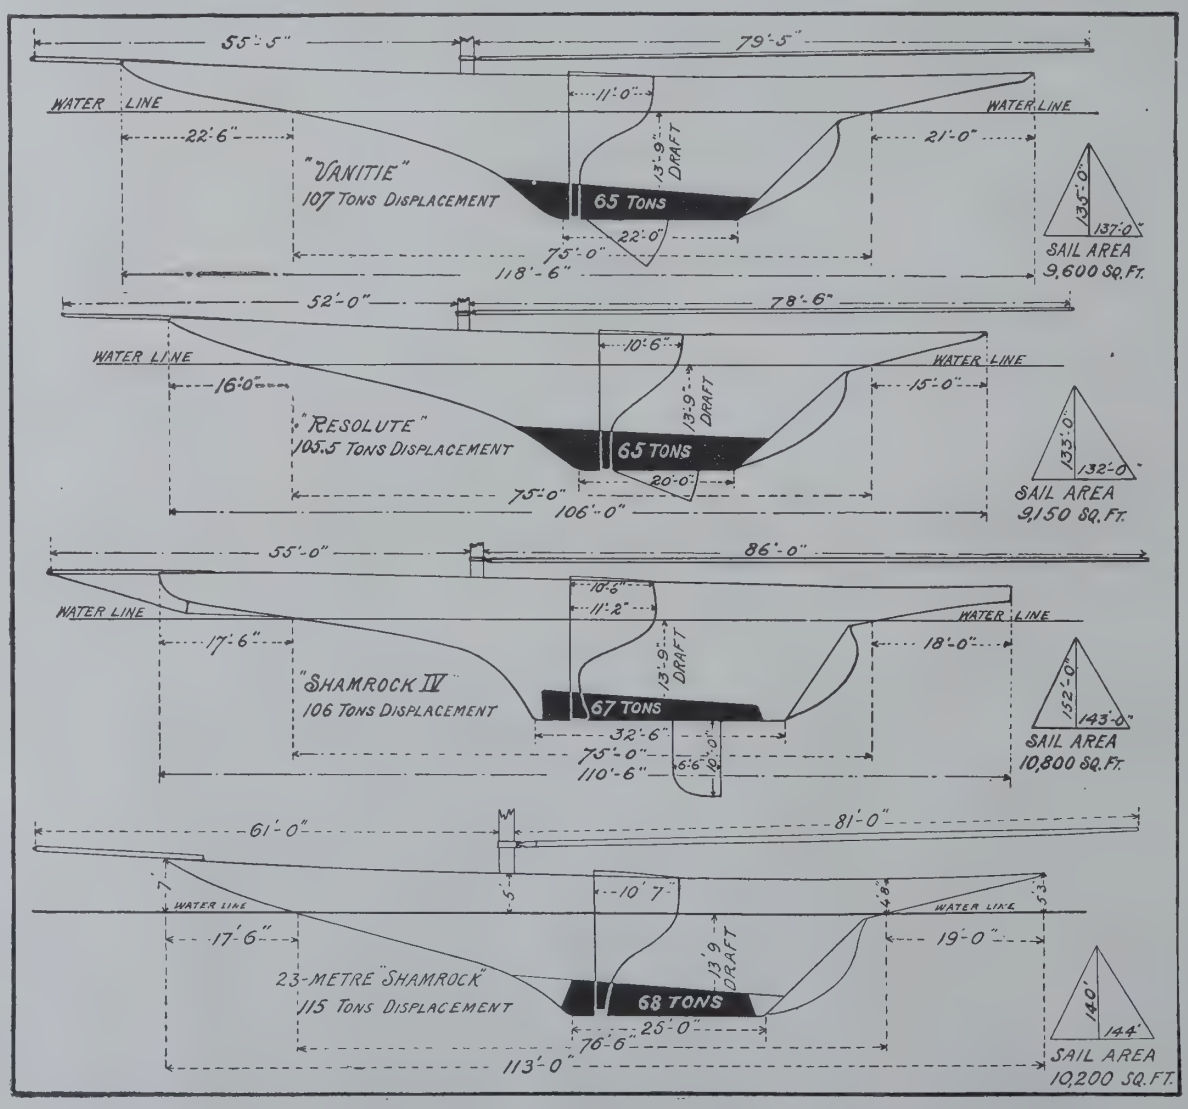
WHEN Sir Thomas Lipton made the very sensible suggestion that in view of the great cost of the modern 90-foot racing yacht, the cup contests for 1914 should be sailed with yachts of 75-foot waterline length, he introduced an uncertainty as to the comparative speed of the 1920 challenger and defenders, which has added a strong spice of interest to the contests. For it is nearly two decades since we had a 75-foot class, and therefore we have nothing on this side of the water that has tried conclusions with the British twenty-three meter (75.4 feet) yachts, which were raced so hard and continuously in European waters in the years preceding the war.



**"Vanitie", right, and "Resolute", left, beating to the outer mark during a windward and leeward trial race for selecting the defender of the America's cup. Note the great reach of the clubtopsail above the topmast (30 feet in "Vanitie") giving the effect of a Marconi rig**

We have good reason to believe, however, that both the defending and the challenging boats are phenomenally fast. "Vanitie" and "Resolute," thanks to their narrow and lofty rig and the refinement of their hulls, are nearly as fast, boat for boat and under equal conditions, as the old 90-footers—certainly they would have no difficulty in saving their time allowance; and "Shamrock IV," judging from the ease with which she pulls away from the twenty-three meter "Shamrock," is undoubtedly herself a very fast boat. But of that, more anon.

This element of uncertainty is answerable, in great part, for the fascination of yacht racing, and it is in full force in the 1920 series for the American Cup. Take, for instance, the battle royal which has been going on between "Vanitie" and "Resolute." "Billy" Gardner (as his host of friends know him) had shown down through the years that he was no mean antagonist for the redoubtable Herreshoff; and when Mr. Cochrane gave him an order for the 75-foot "Vanitie," there was great interest to see what he could do in producing a large out-and-out racing craft of America's Cup type. In the trial races of 1914, "Resolute" established an undoubted superiority, which was repeated and, indeed, emphasized in the trials of 1915. It was believed, however, that "Vanitie" suffered from indifferent handling, and that changes in her sail plan would serve to develop the speed that lies in her well-turned hull. So this year her mast was lengthened two feet, and changes were made in the direction of giving her sail plan greater height in proportion to its base. She was furnished with an entirely new set of Ratsey sails, and she now carries as perfect a suit as the most captious critics could wish to look upon. The changes in hull consist of the removal of the eight-inch rail, thereby saving a thousand pounds of top weight, and also a veneer deck, similar to that first displayed by "Shamrock" in 1914, was substituted for her pine deck, with the result that another 2,000 pounds was eliminated. Altogether, alow and aloft, some 3,500 pounds of weight has been saved, and this was placed, as inside ballast, low down in the hollow keel. The result of these changes, coupled with the excellent handling which she is now receiving from Rear-Commodore Nichols of the New York Yacht Club, has been magical. Of the eight races which have been sailed at the time of writing, five have been won by "Resolute." But of these one should be ruled out because it was a mere drifting match, and in another "Vanitie" was beating "Resolute" badly to windward, when her centerboard fouled a lobster pot, and she dragged several fathoms of line and part of the gear with her, thus slowing the boat down considerably. Of the other six races, three have been won by "Vanitie" and three by "Resolute." It is considered by the committee that the most impressive work by "Vanitie" was done in the eighth race, when, with the advantage of a twelve-knot breeze, she beat the Herreshoff boat handily some two minutes in six miles of windward work.



**Midship section and outboard profile of the 23-metre "Shamrock," shown in comparison with "Shamrock IV" and the two cup defenders "Resolute" and "Vanitie"**

Thus far, the "Vanitie" seems to be master of "Resolute" in winds of from twelve knots upward. In the lighter winds, particularly in drifting matches, "Resolute" seems to have the edge on the Gardner boat. Evidently the Race Committee will have its work cut out in selecting the defender. "Resolute" has the advantage that the challenger will have to allow her one minute and thirty seconds more than she would have to allow "Vanitie"; on the other hand, "Vanitie," both in hull and rigging, seems to be the more robust and reliable craft—a matter which must needs carry considerable weight with the committee in determining which boat to send out to the Sandy Hook course to meet the redoubtable "Shamrock IV."

We know that whichever craft is chosen, the Cup will be defended by an exceedingly fast boat, and the question naturally arises—how fast is "Shamrock IV"? Apparently she will spread from 1,200 to 1,600 square feet of canvas more than her competitor, and, judging from her performance in these waters, she seems well able to carry her lofty rig. The only means of getting a line upon her speed is by comparison with the twenty-three-meter "Shamrock," and in this connection, it is interesting to study her midship section and profile

as shown in the accompanying comparison of the four 75-footers.

The twenty-three-meter boat was built under the International Rule, which was drawn up with a view to getting away from the extremely light construction of the racing yachts of the earlier years of the present century, and producing a vessel combining "habitability with speed." The rating of the yachts under the International Rule is determined by adding the water line length to the breadth; plus half the girth measured at 0.55 from the bow end of the water line; plus a factor, d, which is the difference between the chain girth and the skin girth at the same point, plus one-third the square root of the sail area minus the freeboard. The water line length, it should be noted, is modified by a consideration of the girth at the bow and the stern ends of the water line.

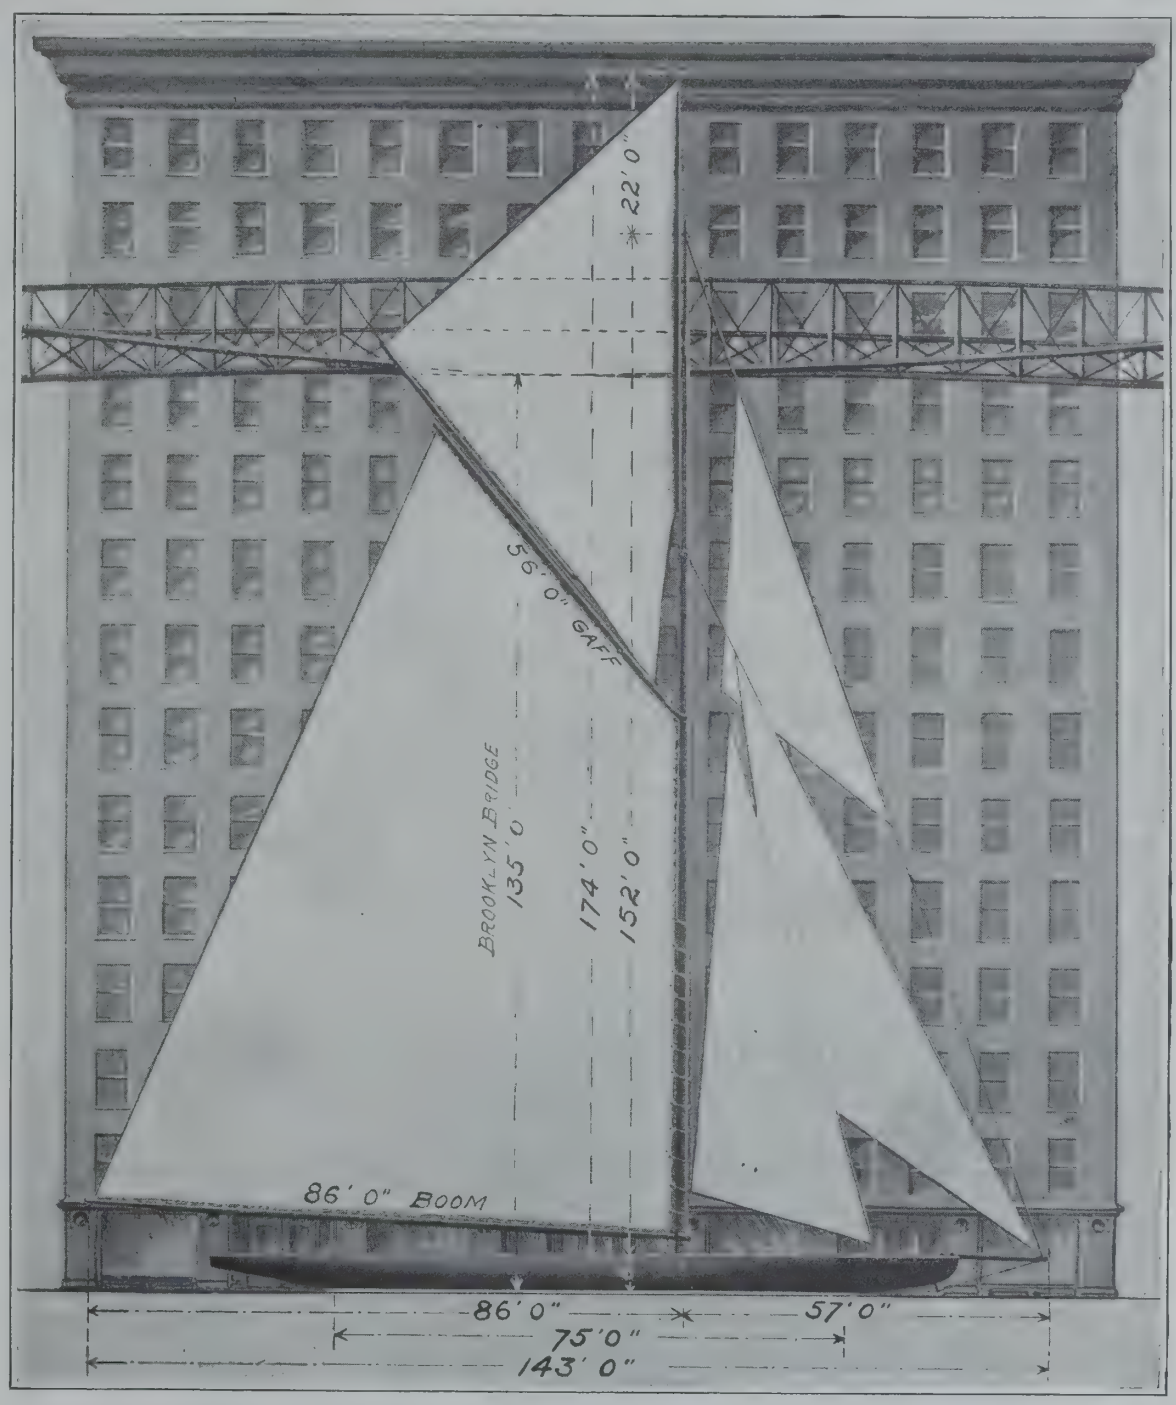
The object of this rule, as in the case of the American rule under which the present races are being sailed, was to produce a deep-bodied boat with fairly sharp and easy ends. But the International Rule goes farther than we do, by prescribing the strength of the scantling and requiring that all yachts must be built under the survey of one of the three classification societies, Lloyds, the German Lloyds, or the Bureau Veritas. Under this rule, the boats have to carry solid masts and must be fitted with complete cruising accommodations. All of the leading countries, with the solitary exception of the United States, adopted this rule, and many fine yachts were built under its restrictions. Among these was the 23-meter "Shamrock," which took the water in 1912 and proved to be the fastest vessel of her class. She was built by Fife, and, like all of his boats, is an exceedingly handsome craft.

The all-important question just now is—how fast is the older "Shamrock"? It will be seen from the accompanying diagram that she is nine tons heavier in displacement than "Shamrock IV" and nine and one one-half tons heavier than "Resolute." The extra weight is easily accounted for by the fact that she has a solid mast weighing two and one-half tons, that she has sixty-eight tons of lead ballast, and that she is a thoroughly equipped cruiser below deck, with staterooms, galley, accommodations for the crew, and every convenience required for comfortable cruising. She has a sweetly turned hull, which should be easy to drive. Like all of the International Rule boats, she carries a large sail spread, the topmast truck being 140 feet above deck. The length from tip of bowsprit to end of boom is 144 feet, which is a foot more than the same measurement on "Shamrock IV" and twelve feet more than on "Resolute."

As to the speed of the twenty-three-meter craft, we know that she swept the boards in British waters in 1912, and the records show that in winning the Queen's Cup off the Isle of Wight, she sailed the forty-eight-mile course in exactly four hours at an average speed of twelve knots. This, however, may not have been as good as it seems, for the reasons, first, that the course is laid in the sheltered waters to the north of the Isle of Wight, and secondly, that the tidal currents are very swift, and it is quite possible for a yacht to have a four-knot current in her favor on certain legs of the course. A more reliable measure of her speed was obtained by Captain Diaper, who brought her across the Atlantic. He tells us that her best sailing, as measured by patent log was 11.7 knots for two consecutive hours. This was done under her greatly reduced ketch rig and in a heavy reaching wind and following sea.

Now "Shamrock IV" is a faster boat than the older craft to windward, as was shown in the first trial race off Sandy Hook, when she pulled out a lead of eight minutes and fifty-eight seconds in a beat to windward of ten and one-half miles. This she duplicated in the second trial race, when she gained 9 minutes in 10 miles of windward work. In reaching she does not do nearly so well, since in the same race she beat the older boat only fifty-one seconds in a close reach of eight and one-quarter miles. Down the wind with spinnaker, she pulls away from the older boat, but not in any such fashion as when they have sheets aboard in a thresh to windward. The yachting "sharps" of the daily press seem to think "Shamrock IV" is oversparred. On the other hand, designer Nicholson, after her first trials, removed several tons of lead because she was too stiff in light airs.

All things considered, there is reason to believe that this will be the closest contest for the Cup ever seen on the famous Sandy Hook course. As in the case of "Shamrock II," which was the best boat hitherto sent over for the Cup, the issue of the race will depend very largely upon the handling of the competing craft. Both the British and the American skippers, for the first time in these Cup races, will be amateurs, and each is recognized as being the ablest representative of the Corinthian sailor in the respective countries.



**The tallest rig among the Cup yachts of 1920 is that of "Shamrock IV." With her water line at street level, the head of her clubtopsail would be level with the cornice of a 14-story office building. To make another comparison, it would extend 45 feet above the underside of the Brooklyn Bridge**

## Gas Laboratory of the U. S. Bureau of Mines

AMONG the many activities carried on by the United States Bureau of Mines is the work being done on gas masks for the protection of workers in various industries. So important is this work that the Bureau at its Pittsburgh station maintains a laboratory for the investigation of gases and the dissemination of information throughout the various industries concerned. The staff of this laboratory is constantly in receipt of problems relating to the protection of workers who may be exposed to gases, and valuable, practical results have been obtained as the result of research. Before the war the Bureau maintained crews trained in the use of self-contained oxygen breathing apparatus with enough oxygen compressed into metal bottles to maintain a man for half an hour. By the use of these the wearer could penetrate mines filled with deadly gases to rescue entombed miners. The experience of these men was of great assistance to the Government in developing the army type of gas mask. These masks differ from the oxygen breathing apparatus in that the masks serve only as filters for removing comparatively small amounts of noxious gases from the air.

The Bureau of Mines is now interested in adapting the gas mask to serve in the industries, where they are finding wide application.

The SCIENTIFIC AMERICAN in its issue of October 25, 1919, published an article on the gas mask in industry, which told of the numerous uses made of the mask, and in the current issue of the SCIENTIFIC AMERICAN MONTHLY for July will be found an article specially written for the SCIENTIFIC AMERICAN by S. H. Katz, Assistant Physical Chemist, Bureau of Mines, which will well repay a careful reading.

As an instance of the effectiveness of gas masks in industry, there is instanced the case of certain painters who were using an air-spray brush in painting some rather deep and narrow wooden bins. As a result of inhaling the turpentine, paint vapors, et cetera, the painters became sick and one man was for several weeks under the care of a physician. As a remedy gas masks were provided and the men worked on the job for months with no further ill effects. The Bureau is doing excellent work in testing the permeability of the material of which gas masks are made, and a schedule of tests and requirements necessary to secure the Bureau's approval has been established.

As showing the great care necessary in selecting gas mask material, Professor Katz quotes the case of the death of James S. Cunningham, foreman miner of the Bureau of Mines, who went down into a storage tank which contained seven inches of gasoline at the bottom, the air therein being charged with gasoline vapors.

He wore a half-hour oxygen breathing apparatus, but it was soon noticed that he was in distress, and in attempting to ascend the ladder he fell back into the liquid gasoline. In the subsequent investigation of the permeability to gasoline vapors of the rubberized fabric of the breathing bag, made at the industrial laboratory, it was found that the fabric was exceedingly permeable to gasoline vapors. Consequently further experiments are in process from the results of which specifications for breathing bags impermeable to gasoline and other vapors will be drawn.

# The Romance of Invention—XIV

## Cottrell—Catalyser

By C. H. Claudy

HUGGING his hard won secret to his bosom, the wild-eyed inventor, hounded by heartless capitalists, crawls to a corner of his miserable garret to die. 'Never shall they rob me of the fruits of my genius,' he breathes desperately. "They would exploit my brains for their own profit, but I will have it all, all, or no one shall have it.'"

Thus the inventor of the novel and the moving picture.

But not always thus the inventor of real life. Undoubtedly many who have been better scientists than business men have failed to realize the financial rewards their discoveries made for others; but, strange as it sounds in this dollar-chasing age, not all inventors want to make their inventions a source of personal profit.

There is Cottrell for instance—Cottrell who invented or discovered (it was a little of both) one of the fundamental processes for which patents have been granted, that of the electrical separation of solid and liquid particles from chimney smoke. "Electrical precipitation of suspended particles" is its proper name, and a very wonderful, if very simple, process it is, of which more in a moment. It is not only wonderful and simple but commercially it is extremely valuable, a process applicable to a great many different industries, and which, when used, in some cases adds the value of a by-product larger than the profits earned by the main product.

*THE reader of this series might be pardoned if he had got the idea that all inventors fall under one of two types—the inventor of fiction, who gets swindled and starved, and the inventor of fact, who gets rich and famous. But Dr. Cottrell's case shows that there is at least one example of a third type—and surely this example makes the best story of them all. There is something that intrigues the fancy in the tale of the scientist who hits on an epoch-making discovery, who commercializes it for a return of millions of dollars—and who, after making provision for his own modest wants, devotes the balance of his royalties to the advancement of human welfare through endowed research. The story of Dr. Cottrell and his Research Corporation is really one of those things that go to support the thesis that truth is stranger than fiction.*—THE EDITOR.

Here was a great chance for a man to get rich from the work of his brains. Cottrell, however, according to those who work with him and know him best, has so great a fund of optimism, and so large a love in his heart for science, for discovery and for making the products of both of service to humanity, that he preferred to devote his talents to better ends than the mere making of money.

So there was no attempt to exploit the Cottrell patents financially. Instead, he offered them to the world, to be used for the benefit of the world.

He did not make them public property, however, or do anything so inadequate as "give them to the government." Dr. Cottrell has pronounced ideas on the subject of making patents available to the general public and holds, and not without much reason, that to give them away is often to bury them, since what is free as air to all is frequently not thought of worth to any. Moreover, manufacturers hesitate to put money and time and plant into the production of an article which anyone can duplicate and anyone can sell. Finally, Dr. Cottrell doesn't believe that industry needs free gifts to keep it alive.

So he first offered his patents to the Smithsonian Institution to be administered by that body, and later, for administrative reasons, and with the cordial consent of the Smithsonian Institution, formed the Research Corporation of New York, and handed his patents over to its use. The Research Corporation is unique among institutions because its charter provides that no dividends shall be paid upon its stock and that the entire net profits are to be used for the advancement of technical and scientific information. In other words, while the Research Corporation is in business to make a modest amount of money, that money is not to be the personal profit of anyone, but is to be devoted to the advancement of science and industry. This, in brief, was Cottrell's idea of what ought to be done with his fundamental patents—that they ought to be made to work for the world, and the profits they made should also be made to minister to the world by being used to aid further discovery and invention.

Whether Dr. Cottrell will be longest remembered for his contribution to applied science, or for his formation of the Research Corporation and any gifts which it may give to the world through its investigations and through the labors of those who win its Fellowships, is not a question which can here be debated. But as the Cottrell patents were, in a sense the "working capital" of the corporation (its actual capital paid in at its foundation was $10,000 and its total capitalization as provided for in the charter, double that amount) it may here be of interest to say a word or two as to what these patents are and what the Cottrell process is, for the benefit of those whose knowledge does not extend to an understanding of one of the most beautiful applications of pure science to the industrial arts.

In many industries a useless by-product is gas of one form or another, which gas carries in it a large quantity of suspended matter. Prior to the Cottrell process, these suspended articles were carried off with the gas or smoke and lost. Many of them could not be screened out as any screen fine enough to catch them would clog up and choke, and the draft would cease. They could not be removed by such familiar processes as passing the gas through a liquid to dissolve them, in some cases because the solids were not easily soluble, in others because of the expense of such a process.

Then came Cottrell with his electrical precipitation and waste-product problems of a hundred industries were solved.

If you were to go into a well equipped laboratory and point a needle charged with a high voltage current towards a plate charged with a current of the opposite sign, you would get, at a certain distance, a distinct wind or air current—sufficient, in the familiar laboratory experiment, to blow out a candle flame. The air impulse is caused by the electrical charging of the molecules of the air so that they are repelled by the one and attracted by the other electrode. Such is the Cottrell process, which can remove from gas the solid or liquid globules which it may contain. Just as the molecules of air do not stick to the plate electrode, so will the molecules of any gas through which the current is sent, not stick to the electrode; the process removes solid or liquid matter from gas, not gas from gas. But, by a regulation of the temperature of the gas to which the current is applied, one or more processes of removal can be carried out. Solid matter can be eradicated at a certain temperature. When this is lowered it produces a liquid content to the gas, when the liquid globules can be removed. The Cottrell process, then, is not only a precipitation but a selection of what is precipitated. In practice the process operates by passing the gas or gases, containing the finely divided solid or liquid particles which are to be removed between two systems of electrodes, one of which is charged so that there is maintained a difference of potential of from 15,000 to 100,000 volts between the electrodes. This difference of electrical potential varies according to the spacing between the electrodes. The small particles of matter becoming electrified in the intense electrical field are precipitated on the electrodes, the result being that the gas comes out practically clear of solid matter, which is all retained in the apparatus, from which it is later mechanically removed.

In smelting and refining furnaces much copper, lead, silver, gold, zinc and other valuable metals is wasted in the smoke and gas from the furnaces. Applying the Cottrell process saves all such waste, to an amount which not only pays for the installation and operation of the apparatus but in many cases delivers a handsome profit besides. In other industries where the fumes given off are noxious, the Cottrell process not only recovers an otherwise wasted dividend but deprives the gases of their noxious elements. Sulfuric, nitric and hydrochloric acids are thus recovered; arsenic, lead, zinc and other poisonous material are removed and in one case at least, that of obtaining potash from cement-laden air in cement works, the recovered material competes with the main product in value.

In practice, the negative electrodes are small, such as wires or chains, and the positive electrodes are large, such as plates or pipes. The electrodes get their current usually through some high voltage transformer and rectifier, in order to obtain from ten to one hundred thousand volts of direct current. The expense of operation of the precipitating plant is but little more than the current expense plus the removal of the precipitated material.

Dr. Cottrell would be the last man in the world to claim all the credit for having set before a waiting world a successful system for removing solid or liquid particles from gas. Many inventors have worked on the same problem and many have been the investigations leading towards the ultimate truth. But none can deny to the Cottrell patents the honor which comes to any which pass the final test of working. There were telephones before Bell, flying machines before Wright, phonographs before Edison, cables before Field, and wireless before Marconi, but they were the men who "did it"; who brought the knowledge which was previously in an abstract and theoretical form, into concrete practice.

So with Cottrell; his patents *worked*, and his brains put electrical precipitation into industrial practise.

Prior to his advent into the public eye he was an instructor in Physical Chemistry at the University of California. He holds a B. S. from that institution, is Doctor of Philosophy from Leipsic University—if he writes his name and titles in full he is Frederick Gardner Cottrell, B.S., A.M., Ph.D. Later he became assistant professor at the university, but then the Bureau of Mines reached out a long arm and grabbed him, and he came—for a little while. He has been with the Bureau of Mines now since 1913, first as Consulting Chemist, then Chief of Physical Chemistry, next Chief Chemist, and is now Chief Metallurgist.

Recently he received the thirteenth Perkins Medal for his achievements, the presentation being made before the New York section of the Society of Chemical Industry. In a speech made about him at that presentation it was said: "It was a familiar phrase at the

# What Industry Can Do for Americanization

## And Some of the Things Which the Industries May Expect from Americanization in Return

By H. T. Waller

INDUSTRY occupies a strategic position relative to the foreign-born. Industry has needed the man with the pick and shovel, the man with brawn, the man eager to make good, the man willing to work under all conditions and at all times. The industrial progress of this nation has its foundation built by the supply of immigrant labor. Industry, however, during the later years has come to recognize a much greater potential force in its unskilled labor than heretofore. It has come to recognize a terrific loss due to misunderstanding; it has realized also that only as understanding is created between employee and employer can best results be secured.

Outside of industry certain social and educational forces have been working many years to create a better understanding of the foreign-born situation. Many have recognized that only as a common language was used could the best of understanding be created and maintained, and to this end educational and social workers have been seeking to develop an Americanization consciousness that would appreciate the potential value of the immigrant. As the work progressed under private and organization leadership it soon developed that in order effectively to carry on Americanization work, in order to reach positively the great army of workers, it was necessary to have classes and activities conducted where these people were brought together in natural groups. This place is the industrial plant. Watch the thousands of employees as they come to and leave work. They come from and scatter to all points of the compass. While in the plant and even in the departments of the plant are gathered large groups of these men who here, at least, have a common point of interest. It is the place where their daily bread is earned, and where they are earning that which will enable them to safeguard and enjoy the future. It has been found also that of all influences that are effective in dealing with the foreign laborer the influence of his foreman leads. Consequently, certain workers in this field have endeavored to develop a plan by which the largest number of foreign employees might be most effectively reached for the benefit of industry, for the benefit of themselves, and for the benefit of the community. For, after all, the interests of the one are the interests of all three, and injure the best interests of one and you will injure the best interests of all three. *For the basic interests of employer, employee, and community are identical.* What then can industry, occupying as it does the strategic vantage point, do?

Industry can and should supply within its organization a person or persons charged with definite responsibility for developing the best interests of the foreign-speaking employees in the plant. No outside agency can come in and do what this agency from within can do. It is necessary that industry shall stick to its job of production and any work that is done must be so conducted as not to interfere with production, but this has a vital influence upon production, therefore, find a man or men with high purpose, social vision, and practical common sense, who will work together with the foreman, assistant foreman, and American workers of industry. The result will be an established point of contact with the foreigner that is bound to be of tremendous value. The men responsible for Americanization in the industry must be men of community vision, not men who are simply creating a department and a job for themselves. This latter point of view would be suicidal to attainment of the object desired.

For when it comes to the question of instruction of employees in the knowledge of English, the ideal is the educational leadership of the community, namely, the Board of Education; and the point of coupling the public educational forces to the industrial power is a delicate one and calls for splendid leadership on both sides. Industry can do more for the promotion of Americanization than any other single agency. In fact, industry must do more, for it is to the best interests of industry that it should be done. The type of community in which a man lives determines more than we now realize the type of production that he turns out. There is, therefore, a compelling economic force which determines industry's place in this great problem.

Today we are facing the problem of a great labor shortage due to natural causes. The fact that foreign labor is returning to Europe is a natural thing, but if industry and the community had paid special attention to establishing a sympathetic intelligent point of contact with foreign labor, the result would have been the establishing of permanent homes in this country on the part of the foreign laborer, to a very much greater degree than has been the case. Only in so far as we are able to establish this personal contact are we going to be able to stabilize labor. Industry must, therefore, take a position of leadership in the problem of Americanization, and where community educational forces do not recognize their responsibility for adult education, then industry must and can take the leadership, and furthermore must see to it that there is a change in attitude on the part of the educational leadership in such a way as to meet the needs of the community which they are serving. One emphatic warning is essential in connection with this problem. Force, compulsion, paternalism should be shunned as though they were a plague. We do not want American citizens as a result of compulsion. Friendship is not a thing that can be forced. Friendship is the result of sympathetic understanding. Friendship will result in the building of an ideal community. Understanding will result in the creation of an ideal industrial relationship. It is possible to secure this through the point of contact established in industry through the agency of Americanization leaders.

In the coöperation of industry and the Board of Education there is a combination of industry and community that is bound to react most favorably upon the individual, the industry, and the community.

Industry holds the vantage point of economic leadership. The solving of this great national problem will depend very largely upon the vision of industrial leaders who recognize the tremendous value of an intelligent understanding.

Industry must then supply leadership, money, and coöperation in the work of Americanization. The leaders of Americanization also must take their position with the leaders of direct production, working with them in close coöperation in order that there may be developed an industrial life based upon sympathetic understanding and mutual helpfulness.—*Address before the National Safety Council.*

### Home-Made Refrigeration

To the Editor of the SCIENTIFIC AMERICAN:

May I have leave to remark the article in your May 15th inst. issue entitled "To Offset the High Cost of Ice," by W. Lambert, and say:

The method explained and illustrated is not new in the field of ice manufacture and mechanical refrigeration and if "the system has been perfected" I would be surprised but also pleased to be convinced of it.

"Perfected" is a strong term.

I take it to mean that the device has been made safe to operate and that it would be operated with commercial profit.

In close observation over thirty years in the fields of ice-making and refrigeration, I hardly think I exaggerate in saying I have known of nearly a hundred concerns that have undertaken the manufacture, sale and installation of machines of this type, none of which survived on account of financial failure.

Further, a number of such machines have exploded, causing loss of several lives and serious destruction of property because someone failed to open a valve that should have been opened before getting up pressure.

Installation of such refrigerating plants should be prohibited unless fitted with safety devices that would render them dependably proof against explosion regardless of the dependability of anyone who might be responsible for their safe operation.

It sounds plausible and has been luring bait for financial "suckers" heretofore, but would-be capital stock investors and contemplating purchasers of such plants would well be warned to heed the record of experience before parting with their good money.

A. C. JACKSON.

St. Louis, Mo.

### Accidents That Happen and Others That Don't

To the Editor of the SCIENTIFIC AMERICAN:

I have been much interested in noting the fact that you are occasionally publishing articles having to do with industrial relations and accident prevention. The article in the April 10th issue, "How Much Is a Worker Worth?" is particularly interesting, but there are a few points in this article that from the standpoint of practical accident prevention I believe should be cleared up.

Excellent as the article is, in these cases it reads either as though the author accepted some hearsay evidence without investigation, or else made his statements without due consideration, and therefore failed to convey the impression he desired. If upon comparing my comments herewith with the article you feel that they are justified and will be of value to your readers, please publish this.

In the third paragraph of the above article the author states that there is scarcely a public school in the United States today that is not absolutely safe for our children. I feel very safe in saying that this article, if called to the attention of any fire prevention engineer of broad experience, would be characterized as being grossly untrue. An illuminating discussion of this subject appears in the July, 1919, issue of the *National Fire Protection Association Quarterly* under the title of "Fire Protection for Schools." It is particularly important that the reader of so reliable a publication as SCIENTIFIC AMERICAN should not be thus misled, because the main obstacle to securing fire safety in school buildings is the lack of knowledge on the part of the public. It is hard enough to overcome ignorance without having to combat misinformation from journals of standing.

I strongly suspect that the discussion of electrical hazards is not based upon sufficiently sound information or long enough experience. Accidents caused by electricity will vary widely, according to the nature of the industry and the use and control of electricity. With standard equipment, and a reasonable standard of safeguarding, accidents caused by electricity will not only be few, but they should cause little time loss or compensation costs, except, of course, in the case of the electrical industry itself. Even here, such accidents can usually be kept down to a small proportion of the total, both in number and loss occasioned.

The incident cited, in which an employee attempted to light his cigarette from an arc drawn by opening a switch under load, if true as stated, shows sub-standard equipment, because the ordinary type of open knife switch should never be used on such voltages as 16,000. Disconnecting switches should be used and they should be so mounted and arranged as to be opened by a long pole.

The reference to some one working on the line and throwing an extra heavy load on the circuit is obviously an error.

Later in the article, the author tells of an accident occurring from an arc caused by the opening, under load, of a disconnecting switch of a 23,000 volt circuit. I do not understand the explanation, because it is stated that the operator "tripped the switch," which, of course, means that he opened the oil switch, killing the circuit. In other words, he either must have opened the disconnecting switch on some other circuit, or else the oil switch failed to work and did not break the circuit as he supposed. In any case, had the disconnecting switches been properly arranged and separated, with proper marking, the accident could scarcely have occurred. The speed with which he opened the disconnecting switch would have no bearing on the matter.

# Wonders in Steel Forging

## The Rôle of Giant Hydraulic Presses and Huge Steam Hammers in Large-Scale Blacksmithing

By A. R. Surface

THE engravings show some very remarkable instances of steel forgings made in France. For the cruisers "Virgniaud," "Danton" and "Voltaire" thirty shells were forged for the turbines, while a number of similar shells went into the steamer "France." An idea of the sizes may be gathered by comparing with the standing men. Among the shells forged for the latter vessel, were one or more plain cylinders having an outside diameter of 10.824 feet and an inside diameter of 10.168. This means a wall thickness of about 3.9 inches. The shell length was nearly 11 feet. The weight of a big fellow like this is 54,800 pounds. While the shell is quite plain, the great length and diameter presented features of difficulty in forging. Another form of shell is one having the same internal diameter all the way through, but a decided variation in the outside diameter. Examples of this are to be seen in Fig. 1. One or more shells of this type were forged for the "France," in which the larger outside diameter is quite equal to the external diameter of the former forging, viz., 10.824 feet. The internal diameter was made 6.855 feet, corresponding to which is a wall thickness of 1.985 feet. This is a very heavy wall indeed. This thickness was maintained for about 2.3 feet of the total length of about 5.3 feet. The thin part of the shell was made nearly 5 inches thick. We have a very remarkable example of the wonderful forgings being turned out in France. This piece weighed 88,000 pounds—quite a chunk of metal.

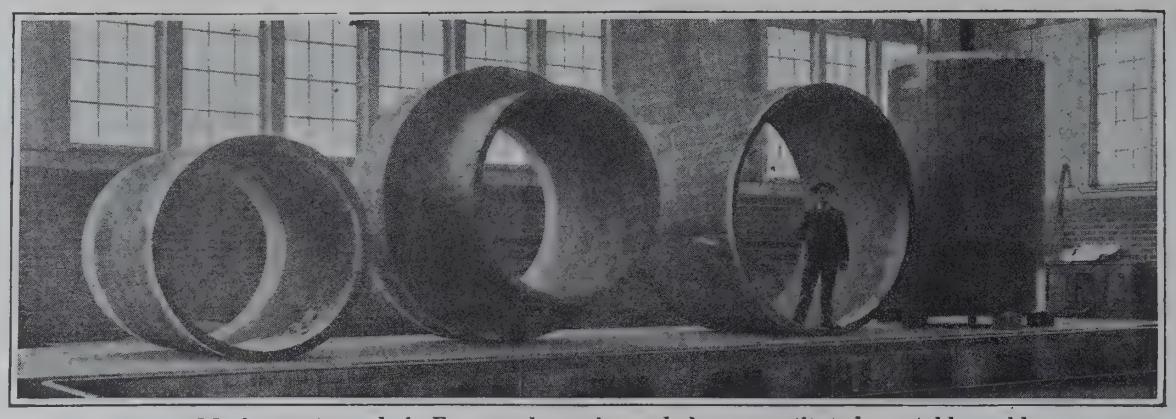

**Fig. 1. Marine parts made in France whose size and shape constituted a notable problem in forging technique**

Perhaps more remarkable yet are certain rings forged by the same concern. The metal was a special nickel-chrome steel. The rings were of considerable diameter relative to the length. The outside diameter was nearly 11¼ feet, the thickness of metal about 5.2 inches, and the length of the ring only 17.71 inches. The work began with a heavy-walled ring of much smaller size, but whose length was just the same. There were six heats in all. The great difficulty in producing the final result centers on the maintenance of perpendicularity to the axis. All the examples illustrated and described so far were forged in the hydraulic press. To these examples may also be added the great shaft for a cruiser shown in Fig. 2. The advantages claimed for the hydraulic press are: Absence of vibration, superior mechanical result, and rapidity and precision in forging. Further, this means of heavy forging lends itself to the forming of the work on a mandrel. Tubular pieces may with advantage be handled by the press. However, the great French works at which the foregoing forgings were produced has not entirely abandoned the percussion idea. They still have three rather good sized hammers of 100, 30 and 20 tons capacity, respectively, besides a large number of smaller units. At last accounts, the works contained, however, eight hydraulic presses whose capacities range from 600 to 8,000 tons.

However, France is not the only country by any means where big presses have come into use. Just prior to the outbreak of the Great War a giant forging press was built for one of our great plants where railroad equipment is manufactured. This press has the capability of developing a pressure of 9,000 tons from its main cylinder. It was built to forge car wheels from hot blanks of steel at the rate of 40 per hour. It has, however, turned them out at a speed of one per minute. The total stroke of the apparatus is 32 inches. Naturally, it is only in the latter part of the stroke when the full power will be required. During the earlier part of the stroke, operation is secured by a water pressure of merely

**Fig. 3. A double-acting steam forging hammer of American manufacture**

30 or 40 pounds per square inch. After this, a pressure of 2,500 pounds per square inch may be used all along the stroke. Finally, during the last four inches, this pressure may be doubled. As the big cylinder has a diameter of 72 inches, a machine of such power is a heavy affair. In the present case, the cap is a nickel steel casting weighing 375,000 pounds. The plunger is also of nickel steel. To its bottom is attached the cross-head, a big steel casting weighing 250,000 pounds. This cross-head casting is thought to be a remarkable example of the founder's art, as in the machining no defect was found. The base is also of cast steel.

The pressure of the press is exerted against the Torsional resistance of four big columns. These are themselves hollow steel forgings, 30 inches in diameter and 33 feet 5 inches long. The compression operation is carried out as follows. The cylinder carried by the cap goes under pressure by the forcing of water into it. This pressure reacts on the plunger and forces it downward. The cross-head with the forming die in place is thus pushed down by the plunger and pressure exerted on the work lying on top of the base. When this pressure comes on, the four cylinders have to resist it. The transportation of this great piece of apparatus across nearly the full length of Pennsylvania involved special problems, and led to the use of a special car with two trucks, one at each end and each containing 16 wheels. There was a connecting bridge frame for the load, consisting of two parallel girders of considerable size.

Another great forging tool was built in the United States, being shipped to the point of use at or near Washington soon after America went into the war. It is not a hydraulic affair. It is a modern machine, however, which is correctly described as a double-acting steam forging hammer (see Fig. 3). At the time it was claimed as the biggest hammer of its type ever produced in the United States. It was shipped to its destination in 14 railway cars. There is a 96-inch stroke and the cylinder has a bore of 40 inches. The ram or hammer is 51 inches wide, 72 inches high, and 66 inches deep, front to back. This ram is notched to provide for the handling of a steel die 72 inches front to back, 41 inches wide and 28 inches high. This itself is quite a piece of metal and is said to weigh 10 tons. The combined weight of falling parts is about 80,000 pounds. A steam pressure ranging from 100 to 150 pounds per square inch was in contemplation. When operating under full steam pressure, the blow delivered is said to amount to 8,000 tons. The anvil, steel anvil cap and steel die together weigh 350 tons.

The standard type of hydraulic press has four tension columns. These hold cap and base apart and resist their further separation when the pressure is on. Ordinarily, such presses have their columns in a vertical position. But this is not essential. Some years ago a Philadelphia concern built a 2,000-ton extrusion press which had its columns horizontal. A notable thing about this press is that the pressure chamber is heated to avoid chilling the metal too much when it goes into position for the extruding operation. The metal has at this time a temperature of 1,650-1,800 degrees Fahrenheit. If the pressure chamber where the metal is put should be cold, the chill would affect the surface of the metal at once. There would thus be both hard and soft metal in the same mass which would doubtless give rise to irregularities in the extrusion. In order that the pressure chamber itself shall withstand the heat and in addition not lose too much tensile strength, a special steel is used for its walls.

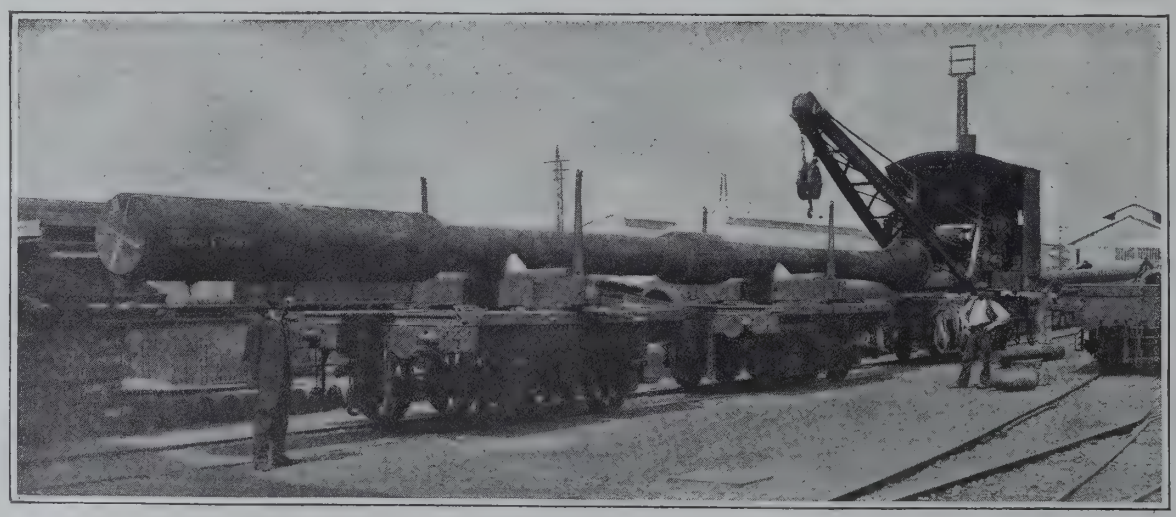

**Fig. 2. Shaft for one of the big French cruisers, produced in one piece by aid of the hydraulic press**

## Bunk Cars That Satisfy Labor

THE ever-growing scarcity of labor has resulted in a demand for better working and living conditions that is not to be denied. Indeed, from time to time these columns have illustrated and told about the model camps and living accommodations now being used by contractors, lumber companies, manufacturers and others in taking care of their labor and trying to make it as permanent as it can be made.

In the accompanying illustration we have another interesting case of the excellent living conditions which prevail in almost every walk of modern industry. In this case it is one of the bunk cars of a western lumber company. A large number of these cars go to make up a long train—a veritable village, to be sure—which moves from place to place as the army of lumbermen is shifted through the great lumber region of the Pacific Northwest. Each car contains comfortable beds, abundant light, and excellent ventilation facilities. This type of bunk car is a worthy improvement over the old bunk car which was no more than a regulation box car fitted up with crude bunks and having one or two side windows for ventilation. Each new car accommodates 28 workmen in comfort.—By *C. L. Austin.*

**This bunk car, which is a unit of a long train, accommodates 28 lumbermen in the utmost comfort**

## Still Another Method of Sawing Big Trees

IT seems that there is no end to the methods developed for simplifying and easing the work of sawing big trees. Within the past few months these columns have had numerous ingenious ideas along these lines, some from abroad and many from Americans, some calling for gasoline power and others using good old man power.

Now it is L. H. Porter of Oregon who has improvised an ingenious arrangement which is shown in the accompanying illustration. Mr. Porter makes use of a hinged upright with cross handle-bar which, when worked back and forth by the operator, transmits the power to a large cross-cut saw through gearing and levers. In this manner it is claimed that the biggest logs can be cut up by one man without undue effort.—By *Alfred Langville.*

**Rocking the handle back and forth causes the big cross-cut saw to go through the log in quick time**

## Speeding Up Reforestation with the Planting Board

ALTHOUGH planting seedling trees by hand is laborious and expensive, annually the Federal Forest Service has to reforest between 10,000 and 12,000 acres of land denuded by fire of tree resources. Forest Service employees as well as natives in the various national forest regions gather the cones from the trees before the seeds drop out, often collecting large caches of cones stored away by the pine squirrels who have hidden the tree fruit away for winter use. Subsequently at the various forest stations, the cones are heated in warm rooms so that ultimately they open and yield up the seed concealed within them.

After being cleaned and graded the seed is planted in nursery beds. When the seedlings are well developed they are dug up and transplanted. To minimize the labor involved in setting the individual seedlings by hand, a planting board is used which is threaded with the seedlings and then placed on the prepared seedbed so that one entire row of baby trees is imbedded in the soil in a single operation. Sometimes when the infant trees are a little larger they are again transplanted, the purpose being to develop plenty of stocky growth and hardiness during the first two or three years of the seedlings' lives so that when set out in the forest proper they will survive and develop into stout, sturdy trees. —By *G. H. Dacy.*

**This planting board enables the foresters to set out a row of seedlings in a single operation**

## A Moonlight Rainbow

NEARLY every one has seen one or many rainbows. But how many have seen a rainbow at night? Yet it is, of course, quite possible for the rays of the moon, reflected from a rainstorm, to form a rainbow in exactly the same manner as the sun's reflected rays form the ordinary rainbow.

The writer, while a passenger on the U. S. Army Transport "Kilpatrick," bound from San Juan, Porto Rico, to New Orleans, La., witnessed, at 8:30 P. M., on October 10, 1919, in latitude 20° 30′ N., longitude 72° W. (just north of Cape Haitien, Haiti) a large and distinct rainbow, due entirely to the rays of the moon. The rainbow, which was west of and in front of the ship, was complete, toching the water at both ends.

The fact that the ship was headed directly into the center of the rainbow and of the storm upon which it was reflected added a portentousness to the already weird and beautiful effect. The rainbow continued to precede the ship for about thirty minutes, and was taken by the superstitious on board as a favorable omen, especially as the ship was at that time in the same waters in which several ships, including the ill-fated "Valbanero" met disaster in the severe storm of a month previous.—By *Lieut C. C. Harshman, U. S. A.*

## Something New in the Way of Airplane Metal Ribs

EXTREME altitudes—the objective of Major R. W. Schroeder and aviators of like ambitions—are not to overshadow another problem of aeronautics, that of multiplying the speed range of airplanes. A new type of airplane rib developed by the U. S. Bureau of Standards, by varying the angle of attack, is capable of making greater speed than hitherto possible with the prevailing wings.

Described as the Parker variable-camber wing, the newly-designed equipment recognizes the principle of construction that if the angle of attack can be efficiently varied from a very small to a very large angle, a wide range of speeds is possible. The properties of the type of wing usually seen are held responsible for the restricted speed of airplanes.

Among the features of the rib structure of the Parker variable-camber wing are: Deformation regularly with the load up to the unit flying load, then remains rigid under further applications of weight, being strong enough to stand up under several times its normal load without failure. Simple, foolproof and easily manufactured are the virtues claimed for the wing. Metal construction is necessary in the new type of rib; other portions of the machine such as spars, bracing wires, and struts are not altered. The essential parts of the new wing are: channel-shaped strips forming upper and lower surfaces of the rib between the spars; compression links are of channel section also and fixed to outer channels by pins, allowing necessary angular motion between links and strips; the tension links are flat strips of steel attached to the same pins which carry the compression links.

A radical departure from the prevailing type of wings, these links in streamline position carry no load, but in a lifting attitude they straighten out and make a truss of the rib, thus preventing further deformation under loads. The links in the first two and last two panels are slotted to permit of the insertion of reserve links. A tail piece is fixed in shape, riveted to the upper strip and constructed to slide over the rear spar. A spring is placed between the rear spar and the tail piece, this spring being used as a tension attachment to the rear spar and the front compression member of the tail piece.—By *S. R. Winters.*

# Baltimore's Tilting Dam

## A Structure That Opens Automatically When It Has Backed Up Too Much Water

By J. F. Springer

THE construction of a dam is not always a case of simply building a structure competent to resist the maximum efforts of the body of water at its back. The engineer may be called upon to do more than that. A possible case in point is the tilting dam at Lock Raven a few miles northeast of the City of Baltimore. The water department of the city desired to increase the capacity of the reservoir-lake Lock Raven in order to meet the needs of the population. It was proposed some years ago to erect a dam with a fixed crest 188 feet above average mean tide and a movable crest 4 feet higher.

All this is simple enough; there are various means of increasing the height of a dam temporarily. However, further upstream was located a big manufacturing concern which used for power purposes more or less of the water before it reached Lock Raven. The elevation of the tail race at the manufacturing plant was 196 feet above average mean tide. With a dam a few miles downstream impounding water back of a crest at elevation 192, the manufacturing concern foresaw possible interference with the effective head of water used by it. The total margin between the two levels was only 4 feet, which would be diminished by the depth of water over the crest. Upon going to court, the manufacturing concern lost. At the same time, the City of Baltimore made a concession to the extent of putting upon the masonry dam, with a crest at elevation 188, a super-dam which goes into and out of action automatically to prevent an excessive rise of water above its own 4 feet of height. That is to say, along the crest of the masonry structure twenty-seven separate and distinct tilting dams have been constructed. With these twenty-seven dams standing in normal position the Lock Raven Dam has its crest at elevation 192. If the water rises 1.5 feet higher, six of the twenty-seven units automatically tilt, the result being a lowering of the crest through this region. If this does not relieve the situation and the water level over the dam continues to rise, then when the level gets to elevation 194—that is, two feet above the maximum crest—nine more units automatically tilt. If notwithstanding this opening up of passage-way, the water goes on up six inches higher—that is, to elevation 194.5—then four more units tilt. Similarly, four units tilt at elevation 195 and four at elevation 195.5. All twenty-seven have by this time gone into tilted position and are assisting to pass the water along. It will be seen that very elaborate provisions have been made to protect the manufacturing plant and perhaps other interests upstream.

Up to some seven years ago Baltimore impounded a part of the waters of the valley of the Gunpowder River by a stone dam 25 feet high. This dam created a small reservoir which was called Lock Raven. Its capacity was only about 510,000,000 gallons at best. Because of the continued deposition of silt, the capacity fell off more and more. In 1900 it had dropped to about one-third of the original. However, by dredging, the reservoir was kept in commission. The new dam is located something less than half a mile farther upstream than the old one. With its crest at elevation 192, the new structure makes of Lock Raven a lake of 620 acres with a storage capacity in the neighborhood of 2,000,000,000 gallons. This is estimated as sufficient storage, if both clear and turbid water are used, to guarantee a daily supply to the city of 90,000,000 gallons.

However, the authorities are looking ahead, and have constructed the base of the present new dam of such width as to permit an increase of its effective height to elevation 305.0. This is 113 feet above the crest of the new super-dam. The lake back of the dam would then be increased to an area of about 9,500 acres with the capacity of 142,300,000,000 gallons.

The general principle of action of the tilting dams may be understood with the aid of the sectional diagrammatic view shown in Fig. 1. The masonry dam

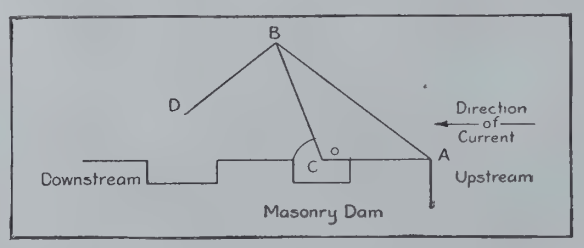

**Fig. 1. How the tilting sections stand when in the closed position, the pressure against the face AB not being sufficient to rock it over**

is surmounted by a structure which is, in section, of a triangular shape. This is pivoted at C. The upstream face is at AB, which presents an inclined surface at about 40 degrees to the horizontal. Under ordinary circumstances, the center of gravity, not shown in the figure but to which we may refer as E, lies upstream from a vertical line drawn through the hinge. Consequently, the tilting dam will of its own weight rest quietly upon the crest of the masonry structure. As the water rises above the level of the point A, its weight at first will be exerted solely in the direction of pinning the movable dam down upon the masonry crest. But after a time, the water will lend no aid to this pinning-down action. The thrust of the water

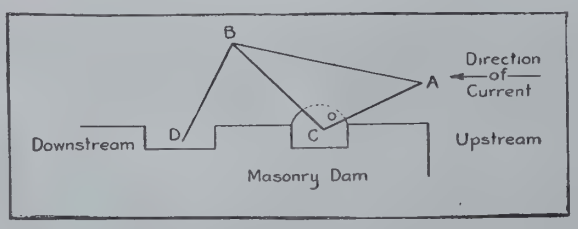

**Fig. 2. As soon as the water behind the section reaches the head for which the section is set, it tilts until the bar D grounds on the top of the masonry**

due to its weight may be viewed as a pressure exerted over the surface AB and perpendicularly to it. We will now, for the moment, take no account of the triangle's own weight. Looking at the matter thus, the triangle ABC becomes a kind of see-saw supported at C. At first, all the pressure exerted by the water is applied between A and E. But as more water comes into action, there is pressure beyond E, between E and B. This will operate against the pressure between A and E. After a time, as the water rises, there will be as much perpendicular pressure on AB above E as below it. There will be no overturn as yet. The pressures are evenly balanced, and the one below E is assisted by the weight of the super-dam. But, as the water goes on up, a time will at last come, if the triangle projects upward far enough, when the perpendicular pressure on AB above E will just equal the same pressure below E. The movable dam is now about to tilt. It is possible so to adapt the form of the triangle and so to distribute the weight of the structure that the dam will tilt at a predetermined level of the water. That is just what the designer, Mr. V. Bernard Siems, Pitometer Engineer, Baltimore City Water Department, has done. Beginning with a type adapted to tilt at 5.5 feet above the masonry crest, he has added others adapted to tilt at 6-inch intervals above that level until a tilting point 2 feet farther up has been reached. In fact, he developed two groups to tilt at the second tilting level.

One must emphasize the point that the tilting takes place automatically. The several classes of dams go into action of themselves without any attention from watchmen, operators or the like. It is the weight of the water and dam and the shape and arrangement of the parts that control. The weight of the water is the only one of these that varies. And it is precisely its variation, expressed as level, that it is desired to control. Probably, the velocity of the flow may have some effect, and also the presence of driftwood. But, disregarding such things, the dam seems a reliable structure which will act as desired when the conditions require it.

In the case of the super-dam a typical unit weighs 1,212 pounds. It is constructed in part of wood and in part of metal. Water-logging may, it is estimated, cause the weight to rise to 1,400 pounds. On this particular type of unit, the center of gravity lies 8½ inches upstream from the hinge and 1 foot 7 1/16 inches above the masonry crest. If we reduce the 8½ inches to feet and multiply the result by 1,212 pounds, we shall get 859 foot-pounds for the moment which the water will have to overcome before tilting will take place.

When the tilting does take place the movable structure turns on C and the foot D coming into contact with the top of the masonry dam, or perhaps the bottom of a depression in its crest, halts the movement. Water can then flow over and through the structure to the downstream side of the general dam.

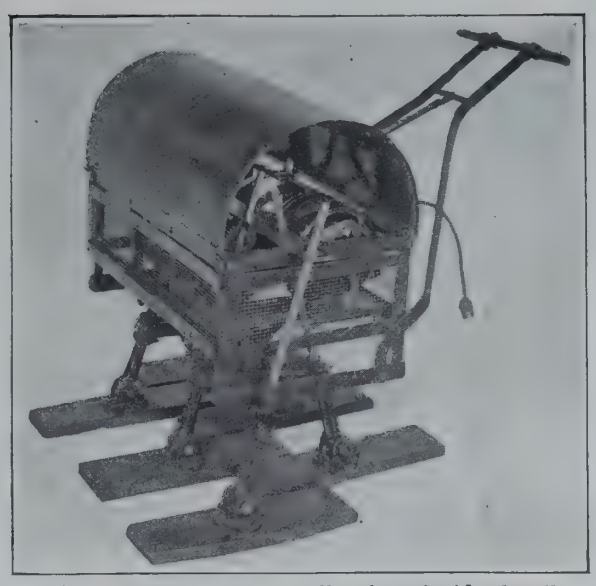
Since the dam has been finished, there have been high water conditions. Types adapted to tilt at the first two levels have actually done their tilting. In many cases where actual tilting has occurred, the tilt has taken place somewhat earlier than the design contemplated. Thus, the tilting has occurred when the water was still 4 inches short of the proper level; in other cases, the action has taken place as early as 7 inches ahead of the level. In explanation of this, Mr. Siems says in effect that as the water goes down and gets near the level of the masonry crest, foreign matter lodges at the toe of the super-dam, so that when it drops back to normal position, it seats itself on this accumulation and rests in a position forward of normal. Similarly, the warping of timbers in the super-dam will have the same effect. Under both conditions the super-dam is in a position where the head necessary for tilting is decreased. On the other hand,

*(Continued on page 22)*

### A Silage Tamper That Walks as It Works

IN order to convert fodder into silage, certain necessary chemical changes must take place in the silo. Investigation has proved that such changes cannot take place to the proper degree if the air contained in the loose fodder is not expelled at the time the silo is filled. And so a very necessary operation in the filling of a silo is to tamp down the fodder to expel the pockets of air, and it has remained for an American inventor to develop a machine that tamps the fodder by walking and stamping on it.

The walking tamper appears in the accompanying illustration. When this machine is placed in the silo, the hood, handles and feet are removed. The frame then stands 19 inches high, 25 inches long, and 14 inches wide, so that it will pass through any opening 20 by 16 inches. The tamper is operated by a one-third horse-power electric motor which drives the tamping mechanism. The machine is supplied with six feet, of which three are advanced at the same time when taking a step. This gives it a stability that could not otherwise be obtained, according to the inventor. Two of these feet measure 4 by 15 inches, while the four others measure 4½ by 15 inches. One of the outer feet has a slight curve on its outward edge, so that it can work close up to the inner wall of the silo. By means of a simple yet ingenious clutch, the feet are dropped as soon as the crank passes beyond the center, thus giving the feet a stamp that can be compared to a man stamping as he walks. The compressive force thus exerted is many times greater than if the machine simply walked as a man does. The speed can be adjusted to suit the conditions, but the normal adjustment calls for 21-inch steps thirty times in a minute. It is figured that the area of a 12-foot silo can be covered four times in five minutes.



**This mechanical tamper walks about inside the silo and tamps down fodder**

### A Load of Automobiles

WE have all read how automobile and truck manufacturers, driven to distraction by the repeated and lengthy rail tie-ups which prevented them from making deliveries, resorted in many instances to the expedient of delivering their machines under their own power. In some cases cars and trucks that were badly wanted at their destinations have been driven hundreds of miles in this way. But as the distance between the factory and the prospective user increases, this method of making delivery becomes more and more a desperate remedy, and calls for a substitute. The photograph herewith, taken on the Ohio River at Cincinnati, shows that where there exists a navigable stream such a substitute is not lacking—though in fact it may not always be an actual substitute, but rather an aid to the more tedious process of road-delivery.

The cars shown on this huge tow were made in Detroit, and were all consigned to Cincinnati and points within reasonably short distances thereof. Just what route was followed in their delivery we are not definitely informed, though we understand that they were shipped from Detroit under their own power to points on the Miami or Wabash Rivers where they could be loaded on barges for towing to Cincinnati, whence they were finally distributed under their own power. It is evident from the width of the tows that the canals connecting these rivers with Lake Erie were not utilized. A lake haul to Ashtabula or some nearby point, followed by a drive to Pittsburgh and floating thence down the river, would have been another alternative. Whatever the route taken by this first impressive cargo, however, the undertaking was so successful that it is planned to follow the same procedure to deliver a quantity of cars that have been ordered for the Memphis, Vicksburg and New Orleans districts. It seems fairly obvious that when we begin to get river transportation in such large blocks and for distances approximating a thousand miles, we have a method of delivery that may be expected to hold its own even after the railroads get back to a normal basis of operation. Lower freight bills, cheaper and easier packing, and a good many other factors seem in favor of shipping automobiles in this fashion—when the water route exists.

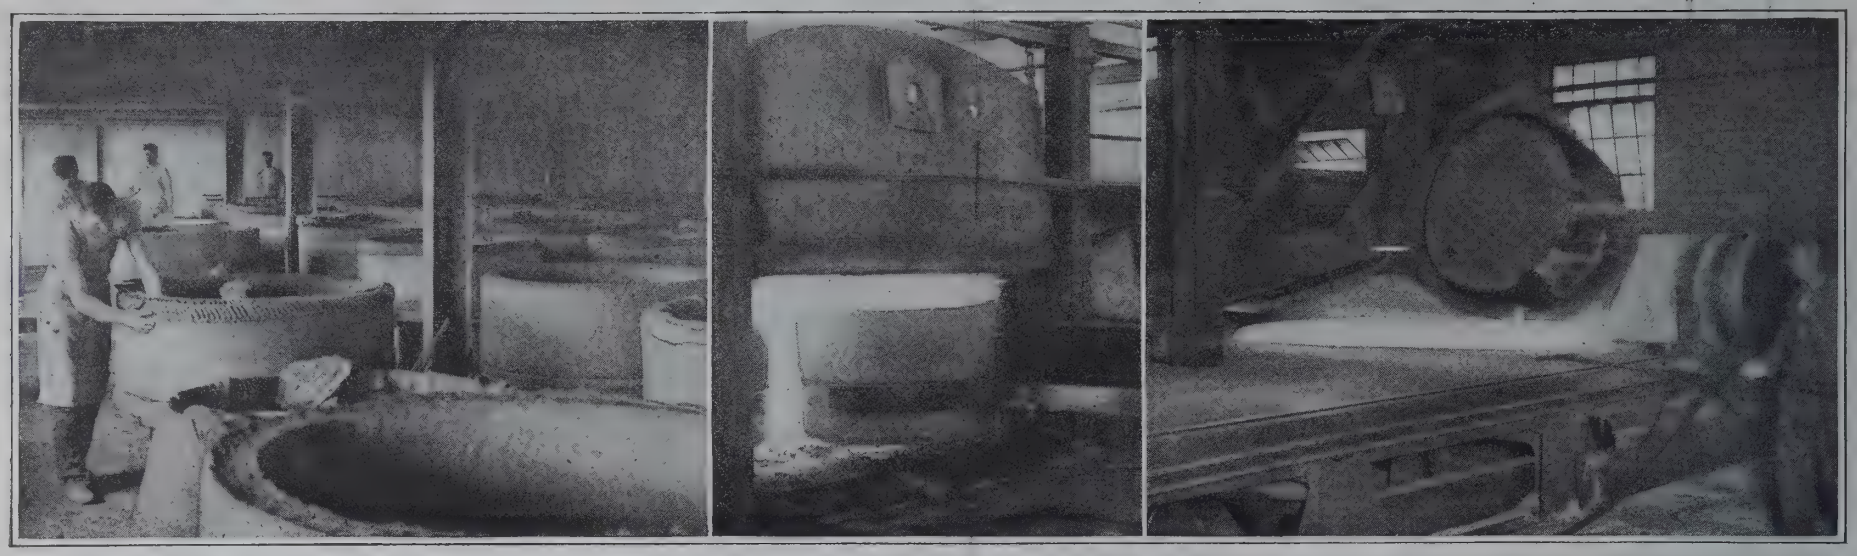
**A huge tow of automobiles shipped in this fashion in the absence of rail accommodations**

### Aiming a Mirror to Film Moving Objects

BY aiming a mirror in conjunction with the lens, instead of the entire camera, as is usually the practise, a French cinematographer, M. George E. Labrely, has succeeded in making motion pictures of rapidly moving objects. Heretofore the motion picture camera generally used has not been adapted to the filming of rapidly moving objects, such as a bird in flight and a rabbit on the run. In the Akeley camera, which has been described in these pages, the entire camera with its lens can be readily and quickly traversed and tilted to follow moving objects. In this respect, and in several others, the Akeley camera has been quite unique. But M. Labrely has introduced a new idea which promises to contribute much to the screen in the way of subjects heretofore held to be impossible for the cinematographer with the usual camera equipment.

It will be noted in the illustrations of the new camera arrangement that M. Labrely moves a mirror while the camera remains fixed. In this manner he has only a small weight to shift, and the movements can be many times more rapid than if the entire camera had to be shifted. The arrangement comprises a flat mirror held at 45 deg. angle in front of the lens, and supported by a long handle, the mirror reflecting the image into the long-focus lens connected with the camera by means of a long flexible bellows. The flat mirror can be aimed in any desired direction, and the image is reflected into the lens which remains stationary. The long handle also carries a simple direct-view finder so that the mirror can be aimed at any desired object. The Pathé type camera used in this case has hardly been modified to take care of the new arrangement, except for the drop board.

**Two views of the ingenious arrangement for taking motion pictures of rapidly moving objects, and two strips of film made in this manner**



*Left:* Preparing clay pots for fusing the glass-making materials. *Center:* Removing the pot of molten glass from the furnace. *Right:* Pouring from the pot on to the molding table for rolling into plate glass.

**Three important stages in the manufacture of plate glass**

# How Plate Glass Is Made

## The Tedious Process by Which Modern Technology Has Been Able to Make Glass without Blowing

### By Ralph Howard

GLASS blowing is one of the oldest industries in the world; it has been a feature of the industry of practically every country of importance from the dawn of history. It is, therefore, not to be wondered at that when preparation of glass in flat sheets for windows and mirrors was first undertaken, the methods followed were the same as those which had been familiar for so many centuries. The apparent absurdity of preparing first in the form of blown bubbles and then in the form of cylindrical sheets, glass which was desired in flat form and which had to be rolled out flat at considerable trouble and risk, was no absurdity at all if we look at it historically. And if we consider that even today sheet glass can be made in this way of reasonably good quality and at lower cost than by any other method, we see a vindication of those who have stuck to the glass-blower.

But the plate-glass industry of today demonstrates that it is not true, as so often carelessly asserted, that glass cannot be produced without blowing. It is more expensive to produce it without blowing, but it can be done, it is done, and a better product is thereby secured. The methods of plate-glass manufacture, however, are not nearly so well known as the older technique which was represented on a cover of the SCIENTIFIC AMERICAN within the past six months.

Plate glass was first made in France in 1688; the first glass rolled without blowing in the United States dates back to 1860 only, and was an unqualified success for the first time at an even later date. So plate glass is really a modern product.

The chief ingredients for plate glass are silica (white sand), soda (soda-ash), lime (limestone), arsenic and charcoal. The chief tool is the clay pot, and this occupies such a position of dominance in the industry that it must be given separate attention in any story of how plate glass is made.

Clays of the various qualities required are mined and exposed to the elements for a time to bring about the first stages of disintegration. At the proper moment finely sifted clays are mixed with coarser, burned grades and water. In this manner the chances of shrinking and cracking are reduced. The mixture is kneaded in a mill, kept sometimes as long as a year in storage bins to ripen, and finally is passed through the laborious process of treading. And if primitive methods have been eliminated in the supplanting of the human glass-blower by the mechanical glass-roller, they have triumphed in the manufacture of the pots. No machinery has been invented by which the same satisfactory plasticity can be given the clay as by the tread of the bare human foot. The clay must be tediously treaded and treaded, many times over; without all this care, when the molten glass goes into the pot some of the ingredients of the latter would be fused out, and the entire effort involved in making both the pot and the glass would go for nothing.

The pots hold something like a ton of molten glass, at a temperature of some 3,000 degrees Fahrenheit; so their chemical and physical perfection must be very high. After they have been molded, they must be properly dried out, another operation to which the greatest care and attention has to be given. No pot may be used until it has seasoned for three months at the very least, and in many cases a year is desirable. And after all this lengthy preparation, the pot is expected to give but 25 days of service; so the glass works is kept pretty busy making pots.

When the pot has been carefully brought to the proper temperature in the oven, it is filled with its charge of raw materials. The process of melting so reduces the bulk of this charge that the pot must be filled three times before it contains a sufficient amount of "metal," as the glass men call this mixture. When the proper molten stage is reached the pot is lifted out of the furnace by a crane. A careful skimming removes the surface impurities, and the pot then is swung overhead to the casting table. The side of this table is lined with adjustable strips, which may be made as high as desired, or as low, to

*(Continued on page 24)*

*GLASS making, one of the oldest of industries, has undergone a startling extension of late years. Not so long ago it would have been easy enough to catalog all the types of glass which were produced. But today there are the familiar blown glasses for windows and other ordinary purposes. There is plate glass, a relatively modern development which does not call for the services of the blower. There are wire glasses that resist shattering to an unbelievable extent. There are figured glasses that let in light but exclude vision. And there are other tricks of the glass-maker's trade too numerous to mention. But perhaps of greatest interest is the apparently simple but really most complex process by which glass is rolled directly into sheets, without the blowing that for so many centuries was considered essential. This is the story of plate glass.*—THE EDITOR.

Protection for the passer-by from flying fragments of the pavement that is being broken up

## Protection from the Ditch-Diggers' Barrage

A HANDY device shown in the accompanying photograph shields pedestrians and windows from being struck by flying pieces of stone that result from breaking through the cement sidewalk or the concrete roadway for the purpose of installing lighting conduits, repairing water connections, etc. It consists of a canvas supported by four pieces of pipe, the uprights being kept from tipping over by heavy circular metal bases. The canvas completely encircles the section of the roadway on which operations are being conducted, and insures that the inevitable bombardment of flying fragments shall endanger no innocent bystanders. The canvas can be removed from the piping and the latter quickly taken down and bundled up for transportation to a fresh scene of activity.—By *A. R. Surface.*

## A Keyboard for the Violin Novice

THE beginner with the violin has difficulty learning to finger the instrument properly to strike the desired notes. This would be all very well if, like the struggles of the novice in algebra or with the bicycle, the learner's infelicities affected nobody but the learner. With the violin, however, this is not the case, inasmuch as everybody within earshot must perforce listen to the raucous results of the student's mishandling of the instrument. To eliminate this nuisance, a device has recently been invented to aid the pupil as well as his neighbors during the trying period when the notes are struck upon the unidigital search system. The invention in question is really a keyboard for the violin. In consists of a curved board which is fastened over the neck of the violin, covering the finger board. On this are cut twelve notches over each of the four strings, and through these are passed aluminum studs which, when pressed by the fingers, lightly depress the string below and give the required tone.

In this way the student may learn the fingering of the violin exactly; and after this has been acquired the keyboard can be discarded and the fingering done directly on the finger board. If necessary, it would be possible to write the names of the keys on the studs for very small children. The keyboard does not in any way interfere with the strings, and it may be removed at any time. The inventors have tried out the device with a number of beginning students, and believe that its use will save at least six months of training.—By *A. H. Kolbe.*

## Powdered Fruit Juice

ONE of the newest fruit products is powdered lemon juice. It is pure juice reduced to a perfectly soluble powder. Details of the process used have not been given out, but it is an adaptation of the well-known spray method of reducing milk to powdered form; indeed, the originaters of the product are powdered milk manufacturers, the largest in the world. The process can also be used successfully with orange juice. The originators intend to erect a California factory for the manufacture of the product.

## Quality of Water and the Setting of Cement

INVESTIGATIONS made with the object of throwing light upon variations in the setting time of Portland cement have recently shown that divergencies of the kind may certainly be attributed in part, if not entirely, to the quality of the water used in gaging, says a British writer.

For the purposes of the investigation four samples of cement were employed, three of which had been aerated for 14, 24 and 48 hours before use, and the cement was gaged with 10 different qualities of water and weak alkaline solutions. From the results given by these samples it appears that the final setting time of well-aerated cement is accelerated by water having alkaline carbonates in solution, while in the case of distilled water, sea water, and water containing alkaline sulphates in solution the final setting time is not appreciably affected by aeration. Comparison of the results with reference to initial and final setting times shows a distinct lack of uniformity, the only inference being that the chemical reactions occurring in the two stages are somewhat indirectly related.

With the object of ascertaining the influence of gaging water upon the initial and final setting times of cement, without taking into account the effects of aeration, tests were made on samples of cement all aerated for 24 hours and mixed with distilled water, pure and containing different percentages of sodium carbonate in solution. These tests, conducted on briquettes seven days old, gave results showing that increasing percentages of the carbonate caused progressive acceleration of initial set and uniform retardation of final set. The investigation points to the desirability of using distilled water in tests of cement in order that results may not be obscured by variations due to the presence of chemical substances in the gaging water.—By *S. Pelham.*

Costumes of asbestos worn by aviators who took a flaming plane aloft to test the fireproofing process to which it had been subjected

How motor cars are shipped from San Francisco without being crated

## Live Loading of Automobiles on Steamships

THE method of handling automobiles employed by a leading steamship company at San Francisco effects a saving of from fifty to seventy-five dollars on each automobile. This saving is effected because it is unnecessary to crate the machines when handled in this manner. The company in question is said to be the only steamship company at San Francisco that can accept autos for export, without the necessity of crating them.

The automobiles are delivered directly from the railroad car and stored in a large bulkhead building. When ready to be loaded on to the steamer, the automobiles are towed to the steamerside by means of an electric tractor. A special device consisting of two pieces of timber and four cables is then attached to the automobile as shown in the photograph, and the car is raised by the ship's tackle and lowered into the ship's hold. The two pieces of timber hold the cables away from the fenders, thus eliminating the possibility of crushing or scratching their members.

This method is also used in taking aboard automobiles belonging to steamship passengers who may desire to take their machines with them.—By *C. W. Geiger.*

## Asbestos Suits for Riding the Flames

THERE has been a good deal of work lately aimed at making airplanes fireproof, or at least sufficiently so to enable the aviator to make a landing, after a fire breaks out, and before the plane is burned from under him. Of course this means, among other things, tests. Some of these can be conducted in the laboratory, but final trials must of necessity be made in actual flight, where the conditions of wind are the same as they would be in practise, and where the navigability of the plane during the fire can be demonstrated beyond question. But—what about the aviator who is called upon to make this trial flight with a burning plane—a plane which it is believed will not burn up before he makes a safe landing, but which has never been subjected to a conclusive test on this point?

Aviators are notoriously inclined toward "taking a chance," but nobody would care very much to send a man up to a possible fiery death. So the answer was found in the asbestos suit which is illustrated herewith. Aviators Campbell and Kerwood recently made such a test flight as indicated, at Atlantic City, garbed in suits like this one. To simulate as faithfully as possible the conditions that would follow a tank explosion, the plane and the aviators' costumes were liberally sprinkled with gasoline, and the match applied. Then the flame-wrapped machine took the air, and remained in flight for five minutes. At the expiration of this time the free gasoline had all been consumed, and the fire died out without a trace of damage.

Then the plane alighted, and it was agreed that the fire-proofing treatment had demonstrated its success.—By *Ralph Howard.*

**This device serves to iron out the dents in automobile fenders**

## Ironing Out Dented Fenders

CONSISTING of a master yoke, two arms of drop forged steel which are controlled by a long screw with a handle, a new device takes only a few minutes to get a dented fender back to health. These two arms are fastened together with a rolling slide and this permits the arms to spread as regulated by the screw. A cavity in the open end of each arm takes care of the various parts used in straightening operations.

In operation the straightening bar is applied to the upper side of the fender while the steel roll attachment is applied underneath. The bent portion of the fender is forced out or upward when the arms of the device are brought closer together by the screwing motion on the handle. When the extended arms of the cross bar are too far apart, as will occur when the curvature of the fender reaches a certain position, the screw is released slightly and the blocks are moved closer together.

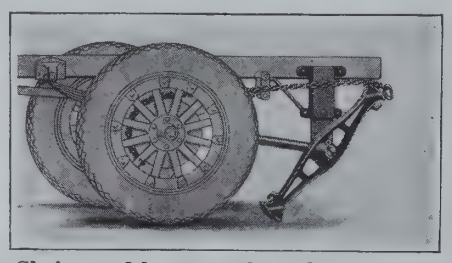
After the blocks have taken out the biggest part of the bump, rolls are attached to the clamp. All forms of fender curvatures may be treated with the device as a variety of rollers are supplied with the arm. A convex roller is used on the outside arm while the inside arm uses a concave roller and they are applied by slipping them into the ends of the arms. When the two arms are brought close together the rollers are worked over the dented surface.

Fenders are not the only part of an automobile which may receive attention from this ironer, as dents in bodies, doors, panels or hoods may be removed as well.— By *Allen P. Child.*

**The protector just under the handle protects the latter from the flame**

## Taking the Hitch Out of Motor Truck Operation

ALL roads are not boulevards, even in these days of excellent roads, and once in a great while the most efficient motor truck becomes stuck in a rut or mudhole or stretch of soft sand. Then, notwithstanding the great strength and surplus power of the modern motor truck, the wheels just spin and spin and the driver is confronted with a nice problem in tractive effort.



**Chains and levers such as these get the motor truck out of ruts and mudholes**

In order to overcome just such delays, an American inventor has worked out an ingenious motor truck attachment which forms the subject of the accompanying illustration. In brief, the attachment consists of a pair of levers and chains placed immediately behind the rear set of wheels. The levers are mounted on a shaft which, in turn, is held by sliding members. These sliding parts are provided with a series of holes, so that by removing the pins from the sleeves in which the slides are held, the shaft may be adjusted to the proper height. When needed, the levers should be pinned to the shaft as shown, with one end of each chain secured to the wheel and the other end attached to the levers. When the wheels revolve, the levers are carried to a position approximately at right angles to that in which they are shown and the chains are automatically detached from the levers after the truck has been moved forward. This forward movement of the truck can be repeated any number of times, each time the chains being connected to the opposite end of the levers as they turn. When not in use the levers and chains can be taken down and stored in a tool chest or other convenient place on the motor truck.—By *Alfred Longville.*

## Protecting the Coffee Pot Handle

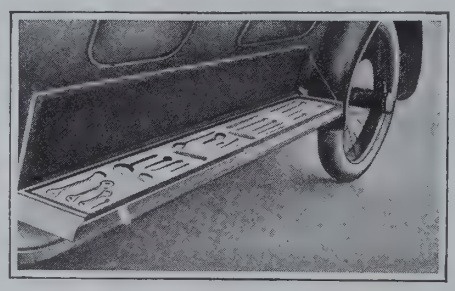
IT happens in the best regulated families—the coffee pot handle pushed too close to the gas flame, and a charred handle remains. This tin protector has been invented to be slipped between the lower horizontal extension of handle and its fastening bracket on the pot itself. It can be easily removed for cleaning and will be found handy in the kitchen.—By *K. H. Hamilton.*

## An Extra Hand for the One-Handed Card Player

IN order to satisfy his own longing to play cards and to supply a means for the half a million others who, like himself, have but the use of one hand, Henry Maier of Brooklyn, N. Y., has developed the ingenious little device shown in the accompanying illustration.

With the device invented by Mr. Maier, a one-handed man can shuffle, deal and hold the cards with fair ease and rapidity after a little practise. The machine is so simple in construction, so compact and light that it can be carried about. It is constructed of metal throughout, and contains no springs, cogs or other movable parts to get out of order. And even a two-handed person can find use for this device, when one of the hands is called upon to do other duties such as minding the baby!

The cards to be shuffled are placed in the simple holder shown in the upper part of the illustration. This holder serves to hold the pack in the same manner as one hand, while the cards are shuffled in the usual manner. The cards can then be dealt by swinging the holder about in any desired direction and throwing the card out with the one hand. Once the cards are dealt, the player's cards are picked up one by one and inserted in the curved slot which holds them as nicely as if a hand were being used for the purpose.—By *Albert Valentine.*



**Here is an idea from Germany—a running-board tool chest for motorists**

## A Tool Chest Built Into the Running Board

GERMAN efficiency no doubt has prompted a German inventor to work out a complete automobile tool chest which forms part of the running board, as shown in the accompanying drawing. The tool chest, it will be noted, is made as flat as possible so that it occupies little or no space. Recesses are cut in the tool chest in order to accommodate the various tools, so that they are firmly and safely held as the automobile receives the jerks and jolts of a rough road.—By *A. R. Surface.*

**This device serves to shuffle, deal and hold the cards with one hand**

## A Wringer for the Portable Tub

SINCE the landing of the Pilgrims at Plymouth Rock, wash-day has been known as "blue Monday," probably because of the drudgery incident to washing and wringing dry the clothes.

And as each successive invention has lessened the hardship of washing and drying the clothes, mechanical ingenuity has been thanked a thousand times. First the washing machine displaced the cumbersome scrubbing board and old-fashioned wooden tub, and other improvements followed at brief intervals. Now, thanks to the forethought of a Danville, Virginia, inventor, a simple attachment has been patented for aiding the washerwoman in wringing dry the clothes.

Instead of using all one's strength in drying the garments by hand, this bit of machinery when attached to the rinsing tub reduces the human strength necessary by one-half. Likewise the clothes are dryer by having applied the mechanical device. Instead of the water running down the sleeves of the operator, as is true when the garments are wrung exclusively by hand, the water is drained into the middle of the tub. The handy wringer is simply screwed on to the side of the tub and used as shown.—By *S. R. Winters.*

**The wringer hook and how it is applied and used in connection with the usual portable wash-tub**

# FAIRBANKS-MORSE

## Keeping the World's Traffic Moving

THE contribution of Fairbanks-Morse to the development of America's railways has been no small one.

Wherever these steel highways have penetrated, you will find railway equipment manufactured by Fairbanks-Morse helping to keep the world's traffic moving.

Our Sheffield Motor Cars patrol many thousands of miles of track throughout the world. Pumps made by us supply vast quantities of water for railroad use. And Coaling Stations designed, built and equipped by Fairbanks-Morse furnish fuel for locomotives all over America.

Dependability in products for railroad use is a primary requisite. All Fairbanks-Morse railway equipment is built up to the standard of which the Quality Seal of this organization is the index.

Our products include Fairbanks Scales—oil engines—pumps—electric motors and generators—railway appliances and coaling stations—farm power machinery, such as "Z" engines, lighting plants, water systems.

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

### Pertaining to Apparel

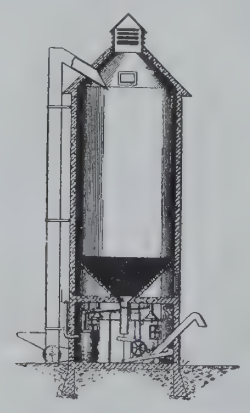
MAN'S GARMENT.—T. GONGORA, c/o Mayo Barrenechea, Box 1052, Los Angeles, Cal. The invention has for its object to provide a garment in the form of a pair of trousers which are reversible, all the seams of the garment being the same on both sides so that when the garment is turned the appearance of the turned side is the same as that of the other side, the pockets being drawn through a slit on the side of the said trousers which are provided with the usual waist band.

### Electrical Devices

INCLOSED NON-ARCHING REFILLABLE FUSE.—A. A. WELLS, 42 High St., E. Detroit, Mich. An object of the invention is to provide a simple and inexpensive fuse plug which will extinguish and choke the flame or arc incident to the fusing of the current conducting material. It is also an object to provide indicating means for showing that the fuse has been blown and no longer conducts current.

### Of Interest to Farmers

MEANS FOR HANDLING EAR CORN.—W. G. ECKHARDT, De Kalb, Ill. The invention relates to means whereby a farmer may treat ear corn fresh from the field. A more specific object is to provide a storage receptacle adapted to receive ear corn at any time after it is practically

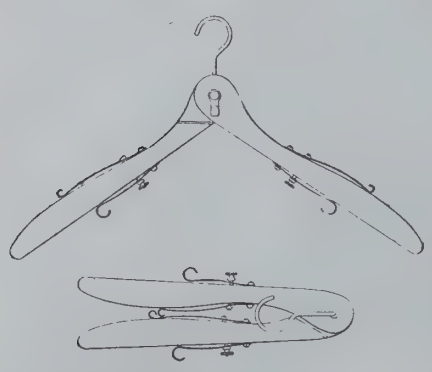


A VERTICAL SECTION OF THE INVENTION

matured irrespective of the moisture that may be contained in it, means being provided in connection with the receptacle to rapidly drive the moisture therefrom. Another object is to provide a receptacle that is proof against mice, rats, and other vermin, as well as serving as a safeguard against molding and rotting.

### Of General Interest

GARMENT HANGER.—F. L. OWEN, 1406 Commonwealth Ave., Allston, Mass. The purpose of this invention is to provide adjustable supporting spring clips with tension screws, on a garment hanger, especially adapted for



A VIEW SHOWING THE INVENTION IN OPEN AND FOLDED FORM

light dresses and waists. The device will not only prevent falling off, as is usual with ordinary hangers, but will securely hold without injury, a large number of garments, thus effecting economy both in hangers and space. A further object is the provision of a compact folding form which makes the hanger especially convenient for travelers.

DARK ROOM LAMP.—J. P. HANSEN, 10 Jacoby Allé, Copenhagen, Denmark. The invention relates to a lamp for photographic use. Among the features are that the light rays are obliged to pass colored glasses before they pass the reflector, the lamp giving an indirect light which can be easily adjusted from one color to another, or mixed at will. The lamp may also be used for the printing of bromide paper, and for the retouching of negatives.

BED.—J. S. BAILEY, care Honolulu Auction Rooms, Honolulu, Territory of Hawaii. This invention has for its object to provide a construction of vertical filler rods, and a manner of connecting the same to the upper and lower hori-

A SECTIONAL VIEW SHOWING A FILLER ROD IN CONNECTING POSITION

zontal rods of the head and foot members or side members of beds, cribs and the like, which will sustain all strains without danger of collapse. The filler rods have curved lugs at their ends, the lug at one end projecting in a direction opposite to the lug at the other end.

TOOTHBRUSH.—L. KARAS, 179 W. 89th St., New York, N. Y. The object is to provide a device of this nature in which that portion of the head containing the bristles is entirely removable so as to be renewable and thus save a great amount of expense in the purchase of new brushes, in that one handle may be used indefinitely and any number of new brush parts secured thereto. The bristles may be cleaned far more easily than those employed with the usual toothbrush.

SMOKING PIPE.—K. B. ABERNATHY, Medicine Hat, Alberta, Canada. The general object of the invention is to provide a smoking pipe with a more nearly perfect combustion to thereby consume the poisonous matter in the tobacco, to prevent the formation of deleterious and objectionable deposits which in the ordinary pipe are formed in the bowl and stem, and to provide a construction whereby a thorough cleaning of the pipe is facilitated.

INDIVIDUAL SEPTIC TANK.—H. BYRD, University, Miss. The invention relates generally to septic tanks and more particularly to a simple construction adapted for family use, and designed especially for use in connection with porous soil or rock formation, but which may be adapted to any formation, means being provided to recurrently operate to discharge only the fluid above the sediment and normally sealed by the contents of the tank.

CONVERTIBLE SWING.—E. B. BLACK, Commerce, Ga. The invention has for its object to provide a swing which may be easily converted into a hammock or reclining swing. The essential feature of the invention is a detachable plate, being connected at one end to the cushion and hinging the cushion to the seat frame so that when the strip is extended it will form a hammock. The device may be constructed of any desired material.

GATE.—H. C. HAINES, Geneseo, Ill. The purpose of the invention is the provision of a gate latch which allows the operating of the gate only when the gate is raised above the normal height, and the latch actuated while in its elevated position whereby the opening of a gate by an animal is prevented. A lever is provided for the latch which when in active position serves as a support for the gate to prevent sagging.

CUFF LINK.—R. A. GILL, Box 640, Berlin, N. H. The object of the invention is to provide a link especially adapted for connecting link cuffs with the ends inclining toward each other instead of lapped in such a manner that they will be held in such inclined position without bending of the cuff or danger of breaking the same when stiff cuffs are used.

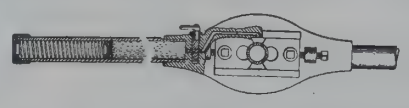
METAL MOLD AND PROCESS OF MAKING THE SAME.—J. D. MCNEILL, 9850 Charles St., Chicago, Ill. An object of this invention is to provide a metal mold from which a large number of castings can be made, thereby obviating the necessity of making a separate mold, as in sand molds. A further object is to provide a metal mold whereby the work of casting certain articles may be materially lessened, thereby tending to greater economy.

FIRE BALLOON FOR SEARCHLIGHT PRACTICE AND FOR OTHER PURPOSES.—J. U. COATES, Exeter, England. The object of this invention is to provide a simple and efficient balloon provided with a heating device comprising a reservoir containing methylated spirit or other suitable liquid hydrocarbon or fuel, and provided with fine apertures through which the vapor of such fuel may issue to be burned as it emerges, and a burner external to, but in association with, the reservoir for the purpose of vaporizing the hydrocarbon.

SHOE LACE HOLDER.—A. G. HALL, 10 Hartwell St., New Brunswick, N. J. The particular object of the invention is to provide a shoelace holder adapted to engage the bow of the shoe lace, which will be very inconspicuous and present a neat appearance and will retain the lace so that it will be practically impossible for the bow to come untied.

### Hardware and Tools

PIPE CUTTING DIE.—E. DE TEIXEIRA, East Setauket, L. I., N. Y. Among the principal objects which the invention has in view are to automatically oil an article during the process



A SIDE VIEW OF CUTTING DIE, HAVING HANDLE WITH LUBRICATED RESERVOIR

of having a screw thread cut therein, to provide a supply lubricant carried by the metal cutting instrument, and to prevent the flow of the lubricant during the inactive periods of the cutter.

GRATING.—H. H. URIS, 515 W. 26th St., New York, N. Y. The invention is more particularly intended for embodiment in street and area gratings and especially gratings of the type employing cross bars or other elements the equivalent of checker work or the like to prevent baby carriage wheels and other articles from dropping between the longitudinal bars of the grating.

SELF-SEATING DOOR HANDLE.—G. W. KENNINGTON, 414-16 3rd Ave., Brooklyn, N. Y. The invention is particularly adapted for use in connection with sidewalk, trap, or other doors which are usually arranged in a substantially horizontal position. Among the objects is to provide a handle which is simple in construction, inexpensive to manufacture and which is self-seating, forming a substantially water-tight joint and laying substantially flush with the top of the door when not in use.

MIXING VALVE OR FAUCET.—J. L. T. POPP, 630 22nd St., Niagara Falls, N. Y. The invention relates to valves or faucets used on bath tubs, basins, sinks and similar fixtures. Its object is to provide a mixing valve or faucet connected with a hot and cold water supply and arranged to permit the user to draw either hot water or cold water or a mixture of the same. Another object is to permit of setting the mixing valve for mixing hot and cold water to any desired degree. The device is simple and not liable easily to get out of order.

### Machines and Mechanical Devices

TENONING AND EQUALIZING MACHINE.—W. F. MCCARTY, Defiance Machine Works, Defiance, Ohio. The object of the invention is to provide a machine more especially designed for accurately tenoning and equalizing sticks of wood or wooden spokes for the wheels of vehicles. Another object is to cut off both ends of spoke simultaneously, and to provide one end of a spoke with a tenon for engagement with a socket in a felly of a wheel. A further object is to dispense with high skilled labor in running the machine.

FILTER.—L. WACHENBERG, Reserve Sugar Refinery, Godchaux Sugar Inc., Reserve, La. Among the objects of the invention is to provide a construction of a compact nature but having large capacity for the output therethrough, but which being relatively small and being equipped with special means for manipulation provides for the cleansing, renewal or interchange of the filtering elements with convenience, but provides ample room to accommodate a considerably large number of filter press units.

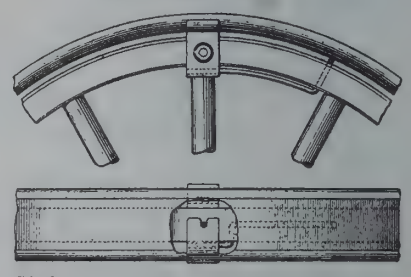
LUG-STRAP CONNECTION.—L. DURAND, 128 Oxford St., Brooklyn, N. Y. This invention relates to picking mechanisms for looms, its object is to provide a lug-strap connection arranged to reinforce the picker stick with a view of preventing the picker stick from breaking when the loom is running. Other objects are to dispense with the usual loop for stirrup straps, and to permit of applying the lug-strap connection to picker sticks of usual construction without requiring alteration thereof.

WELL BUCKET.—C. D. BEHAN, Stigler, Okla. The object of the invention is to provide a bucket especially adapted for use in bored wells, or other wells having a restricted bore, wherein the bucket is normally open at the bottom and is provided with a check valve at its top normally closed and capable of being opened manually to permit the contents of the bucket to flow out.

MACHINE FOR TRIMMING RUBBER HOSE.—F. C. MOORE, Canton, Ohio. An object of the invention is to provide a device by means of which the excess rubber which is forced out between the edges of the vulcanizing press in the final operation of vulcanizing the rubber portions of hose may be economically removed so as to give the hose a proper finished appearance. A further object is to provide a device by which the excess portions on each of the base may be removed simultaneously.

### Pertaining to Vehicles

DETACHABLE RIM FASTENER.—H. J. PRESTON, c/o Lincoln & Clay Co., Santa Clara, Cal. This invention particularly relates to fastening lugs for wheel rims. An object is to provide a fastening means involving a lug and appurtenances thereto, the use of which will accurately center the rim and positively prevent creeping. This object is attained by



A SIDE ELEVATION AND PLAN VIEW PARTLY BROKEN AWAY

providing a lug which, in addition to its primary fastening function, is provided with a secondary fastening means to secure the detachable rim at a point distant, thereby providing with each lug two points of engagement with the rim and positively locking the rim against movement.

### Designs

DESIGN FOR A MOCCASIN.—L. CHAREST, Lewiston, Me.

DESIGN FOR A PIN.—L. D. HACKETT, address A. D. Penney, Townley Bldg., Miami, Florida.

DESIGN FOR A GAME.—J. HARO, 525 W. 123rd St., Apt. 6, New York, N. Y.

DESIGN FOR A STATUETTE.—F. A. KOCH, 269 E. 194th St., New York, N. Y.

DESIGN FOR A TOY.—MILDRED E. SHUGG, 1462 Pacific St., Brooklyn, N. Y.

DESIGN FOR A POWDER CONTAINER OR SIMILAR RECEPTACLE.—C. S. HUMPHREY, c/o Manhattan Can Co., Bush Terminal Bldg., No. 10, Brooklyn, N. Y. This invention has been granted three patents on ornamental designs of a similar nature.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

# UNDARK

## Radium Luminous Material

*"I want that on mine!"*

The gasoline gauge with an UNDARK dial can be seen in the darkest spot of road or garage without tempting fate with a lighted match.

The same 24-hour service is also extended to watches, clocks, compasses, by the use of UNDARK on dials and hands. It makes electric buttons and pull-chain pendants visible in the dark; it's a convenience on locks, door knobs, house numbers, etc., and on pistol sights for straight shooting in an emergency at night.

UNDARK doesn't get dark in the dark

It contains real radium, the most precious of all minerals. UNDARK keeps glowing for years.

The leading manufacturers in many different lines are adding to the usefulness of their goods by using UNDARK.

We are miners and refiners of radium-bearing ore, the pioneer manufacturers of radium luminous material in this country and the largest in the world.

**UNDARK is used on numerous articles, of which the following are the most important**

| | |
|---|---|
| Watches | Gasoline Gauges |
| Clocks | Speedometers |
| Flashlights | Steam and Pressure Gauges |
| Pull-Chain Pendants | Revolver Sights |
| Push-Button Switches | Telephone Mouthpiece |
| Flip Switches | Fire Extinguishers |
| Door Bells | Mine Signs |
| House Numbers | Women's Felt Slippers |
| Hospital Call Bells | Fish Bait |
| Ship's Compasses | Theatre Seat Numbers |
| Locks | Convention Buttons |
| Safe Combinations | Poison Indicators |

**Names of the makers of these furnished upon request**

*UNDARK can be successfully applied by manufacturers in their own plants. It is a simple process. We will instruct operators and organize the work for you. Write for details.*

# The Nitroglycerin Wheeler

No baby tucked in its cushioned carriage ever had more watchful care and skillful attention than the nitroglycerin wheeler gives the concentrated power carried in his rubber-tired wagon.

Back and forth he pushes it between the nitroglycerin store house and the mixing house. He follows a smooth planked walk made exclusively for his use. At one end of his trip the buggy is filled. At the other he pours the nitroglycerin into a mixing machine by means of the long rubber tube attached to the buggy. With this act he gives life and power to Hercules dynamite.

Soon, before the breath of this modern Hercules, great mountains fade away; rivers change their courses; waste and arid lands are changed to fertile fields; metals and minerals, all important in our modern life, are blown from the earth.

The man with the nitroglycerin buggy plays an important part in supplying the enormous force necessary to produce the coal and other minerals and metals which are the pillars of our material civilization. Look around you as you read this. Wherever you may be you will find, if you trace it back, that dynamite made possible most of the necessities and conveniences on which your eye will fall. And a very large part of the dynamite used in this country bears the name Hercules.

## Where the Petroleum Goes

(*Continued from page 3*)

ture should, for the American bulk production, remain practically unaltered. If, then, we find that from one year to the next we are getting out of our petroleum more of one thing and less of another, this can be fairly attributed to changed methods of treatment. Let us examine the figures for what they reveal in this direction.

The Government reports give the amount of oil fed into the distilleries in units of barrels; they give the liquid products recovered in terms of gallons; and finally they show the solid residues —wax, coke and asphalt—in tons. We cannot compare these various items on any basis of weight, for the weight per unit of bulk is the very thing that changes when we start to recover more of, say, the gasoline and less of something else. The only way in which we can attempt a percentage comparison will be on the basis of bulk; and this is perfectly fair, since any shifting of heavier fractions into lighter classifications will show up in this way.

In 1917 our refineries handled 14,487 million gallons of crude oils; in 1918, 15,817 million gallons; and in 1919, 17,096 million gallons. From this we got in 1917 2,851 million gallons of gasoline; in 1918 3,571 million gallons; in 1919 3,958 million gallons. For 1917 the gasoline recovered was 19.7 per cent of the crudes treated; for 1918 it was 22.6 per cent; and in 1919 23.2 per cent. This indicates that the definition of gasoline has been extended and the product debased by the inclusion of fractions that were formerly classified with the kerosene. You cannot increase the gasoline content of a given aggregate of petroleum by nearly 18 per cent unless you thus admit as gasoline something which was not previously admitted. If the 1917 definition of gasoline were to be enforced today, we should have had but 3,367 million gallons of "petrol" for 1919; the shortage would have been worse and the price higher, but as a partial offset the quality would have been better.

If we investigate the kerosene fraction to see what its loss was, we find what may at first be a surprise. The only place from which we can borrow near-gasoline is the kerosene fractions; yet in the face of this fact and of the evidence that we did so borrow, the kerosene recovery was 11.9 per cent (1,727 million gallons) for 1917, 11.5 per cent (1,825 million gallons) for 1918, and no less than 13.5 per cent (2,342 million gallons) for 1919. The answer, of course, is simple; we borrowed from Peter to pay Paul —or dropping figures of speech, what the kerosene fractions lost at the top to the gasoline, they got back with interest at the bottom from the fuel-oil group. Kerosene as well as gasoline has had to be debased to keep up with the procession.

The gas-oil and fuel-oil fractions that comprise the next group represent the biggest single item in oil refining. For 1917 45 per cent of the crudes went in this direction (6,513 million gallons); for 1918 46.3 per cent (7,321 million gallons); and for 1919 44.6 per cent (7,627 million gallons).

The very essential lubricating oil comes next in the scale. This accounted in 1917 for 5.2 per cent of the crude oil refined (754 million gallons); for 5.3 per cent (841 million gallons) in 1918; and for an even 5 per cent (847 million gallons) in 1919. So here, too, we fail to find a shrinkage which would indicate an end of the borrowing process; the lubricating oil supply must have been stretched by falling back upon some of the still heavier components, which had previously been allowed to remain in the solid residue of the refining process.

The Government statisticians recognize, in addition to the four major groups covered so far, a classification of miscellaneous character. We may get some idea of what this covers by examining the detailed analysis furnished for 1919, showing its make-up to the last detail, even to 105 gallons of "ink oil." We find listed here such items as binder, flux, petrolatum, road oil, sludge, distillate, medicinal oils, etc., etc. This miscellaneous caption in 1917 accounted for 4.9 per cent (703 million gallons) of the crude oil treated; in 1918 for 8.1 per cent (1,287 million gallons); and in 1919 for 7.5 per cent (1,279 million gallons). Finally, we are told that refinery losses from evaporation and other causes are held accountable for 549 million gallons of material in 1917, representing 3.8 per cent of the total; and for 611 million gallons in 1918 and 672 million gallons in 1919, in each case 3.9 per cent of the supply of crude oil.

The three solid residues of wax, coke and asphalt are listed in tons, and without data as to their specific gravity it is of course not possible to put them on a gallon basis. They represent, however, whatever of the crude oil has not otherwise been accounted for. On this basis, the 1,519 thousand tons of wax, coke and asphalt produced by the refineries in 1917 must be taken as accounting for 9.5 per cent by bulk of the petroleum treated; while the 1,420 thousand tons of 1918 and the 1,739 thousand tons of 1919 in each instance represent but 2.3 per cent of that bulk. This puts us on the ultimate trail of the borrowings made from Peter for the benefit of Paul. If a greater tonnage of solids in 1919 than in 1917 represents barely one-quarter as high a percentage of the bulk of raw material, we have a verification for the very natural assumption that as we pass upward in the scale of specific gravity, robbing each series of its lighter elements to enrich the preceding series, the final and heaviest series must finally have to pay the bill—there is nowhere for it to turn for replenishment. The figures indicate very clearly that this progressive transfer from heavier to lighter classifications all along the line is precisely what has happened, precisely the manner in which the supply of petroleum products has been stretched so close to sufficiency as has been the case. The various petroleum distillates have been promoted; parts of the old kerosene fraction have been admitted to the gasoline group, the kerosene supply has been recruited from the fuel oils, these in turn from the lubricants, and finally the latter have been forced to admit constituents that were formerly allowed to remain behind as solids.

The variable character of petroleum is further demonstrated by the peculiar showing of the solids, in the classification by sections of the country for 1919. The Atlantic Coast refineries get close to 11 pounds of asphalt out of every barrel of oil treated; the Oklahoma-Kansas and the Colorado-Wyoming fields together extracted but 192 tons of asphalt from 88,000,000 barrels of crudes. The Indiana-Illinois field produced petroleum running 8 pounds of coke to the barrel, while there was not a pound of coke recovered from the California oils, which, however, were richer than the average in asphalt. Finally, as against 4 pounds of wax to the barrel of Pennsylvania crudes, the petroleum from the California field shows less than half an ounce of wax per barrel. For the United States as a whole, the petroleum shows 1.1 pounds wax, 2.98 pounds coke, and 4.4 pounds asphalt per barrel of oil. The oil-barrel, by the way, contains 42 gallons.

It will be of interest and importance to watch statistics for future years and see just how far and how fast we go in the process of pushing our motor fuel down the scale from gasoline to kerosene. Some of us, when we try to start our cars on a regular winter day, are prepared to believe that we have already gone most of the way; but future performance will probably show how hasty this supposition would be.

## *Where Two Hands Do the Work of a Hundred*

JUST like a great hill of ants! That's how someone describes the busy scene at one of our country's large freight terminals. Barrels, boxes, crates, bales, rolls—by the ton—all moving about in every direction, with no collisions, no accidents, no damage of goods. And what keeps everything moving so quickly, so systematically?

When a great ship docks at the wharf an electric hoist, *controlled by one man*, is run alongside, where it lifts huge loads from the hold of the vessel and deposits them on the dock. From this point, the cargo is distributed to various warehouses or to trucks, by means of electric cranes, hoists, storage battery trucks, package conveyors, and sometimes by sturdy little trains pulled by electric industrial locomotives.

The same kind of scene may be viewed in large industrial plants, at coal tipples, ore docks, or any other place where conservation of time and man power is essential. The savings range all the way from a seventeen day reduction in the round trip time of an ocean liner, to the evident economy of a simple conveyor which stacks up bags of sugar at the rate of sixty tons per hour.

In developing the application of electricity to material handling machines, through extensive study of their requirements, the General Electric Company not only serves the industries which are confronted with such tasks. It performs a broader service to all mankind by making it easier to have the world's goods laid down at the consumer's door.

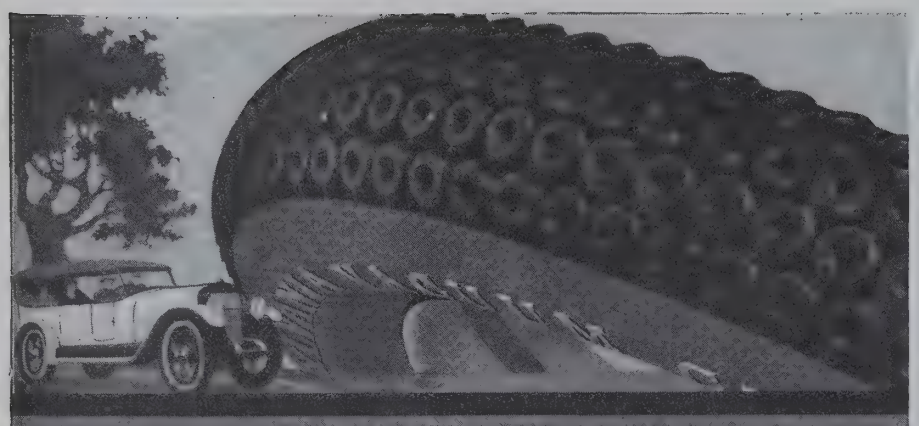
GENERAL ELECTRIC COMPANY



Pennsylvania
VACUUM CUP
CORD TIRES

*Why They Are Economically Priced*

BUILT by skilled, well-paid, progressive workers — with the most modern equipment and time- and labor-saving appliances—

In what is conceded to be one of the most up-to-date rubber plants in the industry.

Marketed under a zone selling system which efficiently distributes an ever-growing volume with true merchandising economy.

Tire buyers are therefore privileged to buy Vacuum Cup Cord and Fabric Tires and "Ton Tested" Tubes *at the price of ordinary makes.*

See your local Pennsylvania dealer and be convinced.

Adjustment basis—per warranty tag attached to each casing:
Vacuum Cup Fabric Tires, 6,000 Miles
Vacuum Cup Cord Tires, 9,000 Miles
Channel Tread Cord Tires, 9,000 Miles

## Romance of Invention—XIV

(*Continued from page 8*)

University of California, anywhere from the Department of Botany to the Department of Physiology: "Oh, go tell Cot about it. He won't know anything about your subject, but you won't talk to him ten minutes before he'll give you an idea.'" And this seems entirely characteristic. His own work he credits largely to those who have worked with him, but it remains for others to refer to him as a catalyzer of men. Catalytic processes, it will be recalled, are those in which some agent produces results while remaining itself unchanged. And Cottrell seems to have that type of mind, which inspires in others new thoughts, new ideas, often new ideals, without such inspiration taking anything from his own brain. Thus, the demulsification of the California oil well water was solved by a suggestion of Cottrell's, a thing for which he takes no credit, yet which is surely his, since he but applied to the problem the same methods and the same reasoning which solved the electrical precipitation problem of solid matter from gases.

The first installation of the Cottrell process in commercial work was at the Hercules Powder Plant at Pinola, California, where there was a small sulfuric acid plant. A twenty thousand volt current was used, the insulated high potential electrode being covered with pubescent (hairy) asbestos. It was successful but the plant was too small for it to operate at a profit. Nearby, however, was the Selby Smelter, a large plant near a tunnel of the Southern Pacific Railroad, which tunnel was frequently fouled with the sulfur trioxide fumes from the silver dissolving house. Legal proceedings by the railroad threatened to stop the operation of the smelter. Then came Cottrell to the rescue with a small electric plant which is running today, and the harmful fumes were caught and metamorphosed into useful dilute sulfuric acid, which became a by-product of the smelter. The tunnel was cleared, legal proceedings were stopped and the Cottrell process was on the map. Fume-pestered farmers all over the West who had sued smelters right and left succeeded, with the Selby plant example before them, in convincing judges and juries of the fact, that they were not asking the impossible of the smelters when they demanded suppression of the fume nuisance, but only asking for needed relief which could be readily obtained.

As the fume problems of the various industries differ so widely, it is obvious that special apparatus and special arrangements must be made to cope with each. But there have been none which the engineers of the Research Corporation have not been able to solve. By having the patents in the hands of engineers whose desire is to get the process working, to get it in the hands of those who can use it, and who are asked to pay, not a huge personal profit, but merely a nominal license profit, which is turned into the corporation for further scientific work, there is eliminated all the matter of money-making expediency which so frequently retards, rather than develops, an invention. The Research Corporation is paying its way, is spending more a month than it originally had capital for a start, is employing a large staff to do its work and has established a Fellowship in Applied Science, awarded yearly, to stimulate scientists, inventors and discoverers to further research and assist them in such labors.

Dr. Cottrell prefers to work where he is of the most use rather than where he will make the most money. He seems to prefer to spend his life (he is forty-three years old) catalyzing other men into mental activity, making new discoveries himself, furthering the comfort and convenience of the world at large than in developing a big income for himself.

But if he builds no monument of wealth to his name, he has done that which is of infinitely greater worth. To a world just learning how unnecessary any waste may be he has given a very potent means of saving waste, and devoting the profits of his wonderful discovery to the increase and wider diffusion of valuable knowledge among all men. More power to him, and may there be others like him in the days to come.

## Baltimore's Tilting Dam

(*Continued from page 12*)

friction due to corrosion, etc., at the pin tends to increase the head required.

It should, of course, be understood that the diagrammatic section is much simpler than the real thing, composed as the latter is of timber and metal parts. The slanting upstream face which restrains the water for a time is a wooden diaphragm bolted to a metal frame. In one type of unit there are two triangular frames of angles and plates. These are set 8 feet apart, center to center. On the upstream edges of the frames are bolted three I-beams which serve a purpose similar to that of joists. The wooden decking is bolted to them after the manner of flooring. However, this decking presents a surface 12 feet long, measured parallel to the dam, and a little over half as broad, measured from toe to crest. Anchor blocks of metal were installed for the purpose of providing a means of pivoting or hinging the unit dams to the top of the masonry construction. As the crest was provided with keyways which are to be used when in the future the dam is enlarged in thickness and height, the center one was utilized as a suitable depression in which to secure the anchor blocks. When a block is in place the axis of the pivot hole is 2 inches above the masonry crest.

The manner of fixing the anchor blocks securely in place is of interest. An anchor block consists of three separate castings. The principal one has the pivot hole. It was readily set in place in the rectangular groove in the top of the masonry. The remaining two pieces were then slid in to approximate position. Each of these pieces had a toothed surface to present to the vertical wall of the groove. One was located on the upstream and the other on the downstream end of the main block. By means of wedges, these two pieces could be made to extend the body of the main block so as to fill the masonry groove from one vertical face to the other. If, now, their positions could be rigidly maintained, the block should be held very firmly indeed against any overturning action exerted through the pivot. In order to meet this requirement, space underneath the casting was left when setting it and this was later on filled with a grout made of cement and sand (1:2); and the interstices between the small castings and the big one were filled in with lead.

The frames of some, at least, of the units were so dimensioned and shaped that upon tilting the foot D rests in the next keyway downstream. At this juncture, the wooden face, while tolerably flat, has not yet reached a full horizontal position. This means that some amount of face is still presented to the oncoming water. However, after making all deductions for this face and part of the framework, there is a clear opening, for this type, nearly 15 inches high. Here the water flows over the masonry crest and beneath the wooden face.

A question that may now be put is this: Will the dam, after it has once tilted, reverse itself upon subsidence of the water? Usually, the dam reverses, it is said, when the water falls to elevation 188.75 feet or a little less. This would seem to mean that when the depth of water on the masonry crest gets down to 9 inches or something less, the center of gravity has moved over to a position a trifle upstream from the pivot.

# Five Men Around the Table

## *Automobile History in the Making*

***Henry M. Leland, Wilfred C. Leland and some of their Associates in the Lincoln Motor Company***

AROUND a table in a modest office some eighteen years ago, five serious-minded men sat in consultation. They had sat in consultation many times before. For a number of years these same men had worked and thought and studied and planned together, always with the same objective—to do things better and to make

*A conference of 1902 which marked the sunrise of America's motor car industry.*

things better than they had ever been done or made before—in fine machinery, fine tools, and internal combustion engines.

"Yes, boys, that's good, but it isn't quite good enough." It was the eldest of the group who spoke. "This piston fits perfectly into this particular cylinder," he said, "but we must make every piston so exact, and every cylinder so exact, that every piston will fit perfectly into every cylinder. Then, if anything happens to either, it can be replaced by another; and the car owner will not be obliged to buy both cylinder and piston if only one should be injured.

"And this wrist pin," he continued, "must be made accurate to the half-thousandth of an inch. Its bearing must be made with the same precision. Then there will be a perfect fit, and practically no wear-out to it. Otherwise, the slightest 'play' means early wear, and destruction."

And on, and on, and on, the conference continued for hours, and was resumed day after day—until the last bolt and nut had passed scrutiny.

Earnest and thoughtful, tho these men were, little did they dream of the far-reaching influence of that council upon what was to become one of the world's greatest industries, an industry which has now become one of the great factors in civilization.

The leaders of that history-making conference in 1902 were Henry M. Leland and Wilfred C. Leland.

They were discussing and passing judgment upon an automobile design, upon specifications and materials; and determining upon the accuracy to be followed in making the various parts— accuracy expressed in thousandths of an inch, and even in fractions of a thousandth.

Three cars were completed, and subjected to most rigorous treatment. Materials were ordered to build three thousand of them. These were eagerly absorbed and more than twenty thousand were distributed within the next five years.

It is strikingly significant that many of these original Leland-built cars are still in service; and many of the engines after eighteen years are doing duty in stationary power work—in the small shop, and on the farm.

It was this Leland-built car which brought honors to America when it was awarded the Dewar Trophy—a tribute bestowed annually by the Automobile Club of Great Britain in recognition of the greatest advance in automobile development.

*The same five men in 1920, in a conference which presaged new and better things in motor cars*

From a number of cars in stock, the Club's technical committee selected three. These cars were entirely disassembled, down to the very last piece. The parts were then mixed promiscuously. Eighty-nine parts were withdrawn and replaced by like parts from service stock.

Mechanics then assembled three "new" cars with parts taken at random, there being nothing to identify their original assembly. Not so much as file or emery cloth was used, or needed; yet every part fitted as perfectly as in the car from which it was taken.

In many instances, inaccuracy of the thousandth part of an inch—even inaccuracy so fine as a third of the thickness of a hair from your head—would have meant failure. But the test was an unqualified success.

The profound impression made upon the manufacturing world by that remarkable achievement, thousands will still recall.

It immediately compelled recognition of the Lelands as foremost exponents of precise workmanship and true standardization—a recognition more complete today than then.

A few years later, another Leland-built car was awarded the Dewar Trophy. This time it was the result of the eminently successful test of the then new electrical system of automatic cranking—lighting—ignition.

Leland-built cars were the only American product ever to receive that much coveted tribute, and the only make of car thus honored twice.

In 1914, twelve years after the conference first here pictured, there was another series of consultations. These men were now developing, modifying and refining the V-type eight cylindered engine with which the Lelands were once more about to revolutionize the trend of fine car making.

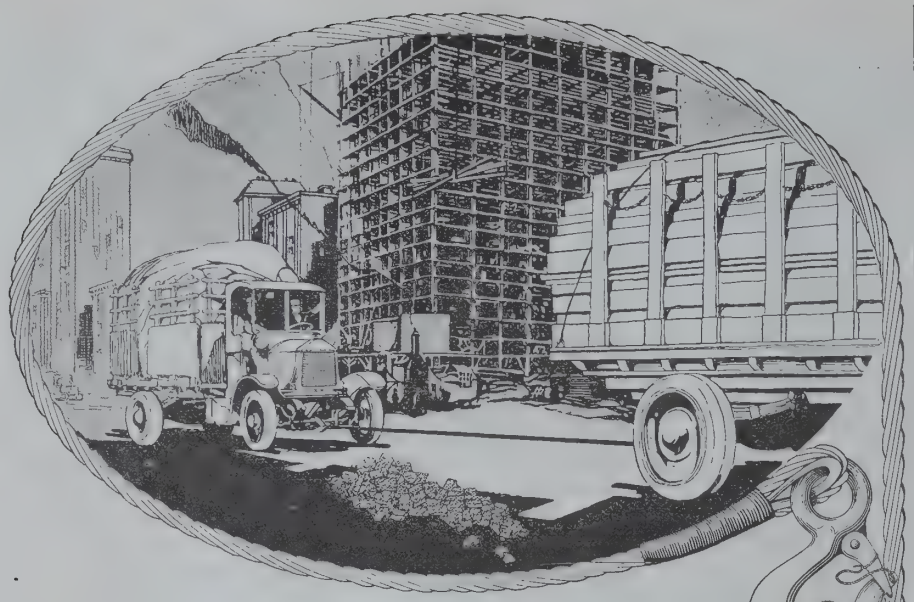
January 7, 1920, five men were again in conference. They were the identical five men who were around a table eighteen years before. They had been in continual relation for more than twenty years, always with the same objective—to do and to make things better—to build motor cars better than they had been built before—cars of greater comfort, greater convenience and greater utility.

They are men who have inaugurated many epoch-making periods in the more important motor car developments.

In the conference of January last, the same five men, with scores of earnest, loyal associates, were preparing to inaugurate another epoch-making period; this time the new Leland-built car—a car such as thinking men and men who know the Lelands would naturally expect.

It is a car not only the outgrowth of eighteen years' experience and devotion to fine car making, but a car expressing, more truly than ever before, Leland foresight, Leland courage, Leland initiative, and Leland determination to achieve—and to surpass.

LINCOLN MOTOR COMPANY DETROIT, MICH.



# On Time!

Time is money with a motor truck. Delays eat up profits and stall production. Safeguard against them by equipping every truck with a

## POWERSTEEL TRUCKLINE

This dependable towline would hold an elephant. It's made of world-famous Yellow Strand Wire Rope. Attaches instantly, securely. Retails, east of Rockies, at $11.30 with *plain hooks*; $12.75 with patented Snaffle Hooks.

BASLINE AUTOWLINE is a smaller line, for towing passenger cars. Also made of Yellow Strand Wire Rope. Can be used to pull car out of ditch on your own power. It's the "Little Steel Rope with the Big Pull." Patented Snaffle Hooks. At dealers, $6.95 east of Rockies.

POWERSTEEL AUTOWLOCK, also made of Yellow Strand Wire Rope, is protection against car or spare tire thieves. Has sturdy, non-pickable spring lock. At dealers, $2.80 east of Rockies.

## How Plate Glass Is Made

*(Continued from page 14)*

gage the production of plate of any desired thickness. The semi-fluid glass is now poured from the pot on to the table, and a huge roller passes over it, ironing it out into a layer of uniform thickness. This might seem to be the end of the matter, but there is still a lot to worry about before that sheet of glass is ready for the market.

In the first place, while now substantially solid, it is still far from cool; and if allowed to cool without special treatment, it would crack, curl, shrivel, and do all sorts of unpleasant things. So it goes to an annealing oven, where its temperature is brought down by slow and easy stages, in such a way that no damage to the plate results. On leaving the ovens, it doesn't look much like the beautiful smooth sheets of plate glass which we see in the store windows. Its surface is rough, opaque, altogether unprepossessing—but only the surface, for inside it is clear as crystal. So it goes to the cutter who takes off the rough edges and squares it to the proper dimensions; and from his hands it passes to the grinding room.

The grinding table is a big revolving platform of iron. It is prepared for action by being flooded with plaster of paris and water; then the slab of glass is lowered upon it with the utmost care, men climb on top of it, and tramp it into place until it sinks well into the plaster and the latter sets about it. Still greater security is got by pegging with wooden blocks; then the table is at length set in motion. The grinding is done by revolving runners. Sharp sand is fed on to the glass, and a stream of water constantly flows over it. After the first cut by the sand, emery is substituted, and then finer emery, and finer still. At the conclusion of the grinding process the plate is carefully inspected. Nicks, fractures and flaws are found, and the plate is squared upon again in smaller size or sizes to eliminate these, or if they are too serious to permit this, it is fed back into the pots as cullet, or broken glass, of which a certain proportion goes into each charge. The parts that get past this inspection are polished much after the same style that regulated the grinding operation, the only difference being in the abrasives, which are here of course much finer. Rouge (iron peroxide) is the standard here, and it is worked over the glass with felt runners, so arranged that every part of the glass passes under every part of the runners, tending to compensate for any slight irregularities.

Altogether the grinding and polishing reduce the plate to about one-half its original thickness, or even less. The material washed away represents a permanent loss, since it is so commingled with the abrasive particles that it would not be profitable to attempt its recovery. New plate glass is a delicate sea-green, when viewed through the edge. When exposed for a period to sunlight this fades slowly to a yellow or light brown, which makes it difficult to match new glass in with old.

When the plates are to be bevelled, a good many additional processes are necessary. The roughing mill or roughing wheel is a circular cast-iron disk having a fine-cut corrugated surface about thirty inches in diameter. This revolves rapidly, while sand or carborundum is conveyed to it from above through a hopper with a stream of water, the sand giving the desired roughness between the iron and the glass while the water minimizes the frictional heat. The edge of the glass is brought into contact with the swiftly moving roughing wheel, which revolves in a horizontal plane, and the sand cuts the bevel to the desired depth. Curves and patterns with incurves, miters, etc., require great skill on the part of the operator. Then a second roughing process follows in a second mill, with a finer abrasive, designed to smooth out some of the troughs left by the first cut. After this a mill of fine sandstone, with no intermediary save water, is employed for what is known as the smoothing out. The polishing wheel brings the surface of the bevel to a dull, milky finish by means of powdered pumice. Then comes the final high-gloss polish, effected with rouge and a layer of heavy felt.

The edge of the glass, according to the use which it is intended to make of the plate, is rough ground, squared, or chamfered as desired, and often is polished much as is the bevel. Ornamental lines are frequently cut about the edge, etc., and this is done with a very sharp-edged wheel in the first instance, followed by polishing operations.

## Orchard Medicine Quacks

OUR idea of a genuinely discouraging farm experience is that of a Pennsylvania orchardis who, in a conscientious effort to control pests, used the wrong spray material and killed 22,000 trees. This orchard tragedy stands out be cause it is exceptional as to size, but it could be matched as to essence by thousands of other authentic instances. Like drinking medicine in the dark out of a bottle labelled with cross-bones, is the use of the wrongly picked or wrongly applied fruit spray. Because the appearance of dangerous orchard pests, reaching now to practically every section and locality, makes spraying absolutely necessary, the danger in the situation, unless care is taken, bulks large.

And a deplorable, and widespread fact, is that most such orchard tragedies happen to progressive, enterprising fruitgrowers, men who oftentimes are experts in their line. It was thus with the orchardist who lost 22,000 trees. The error in most cases comes in following advice—for this new department of fruitgrowing is one on which the average grower must seek information—given by irresponsible, unreliable people, the quacks of the "tree medicine" business. In a financial way, a vicious patent medicine can play about as much mischief in the farmers' business as it can anywhere.

Ultimately authorities will see to it that farmers are adequately protected against quacks and frauds, but until this day is fully here, the safe thing is to go straight to the state college or experiment station fo radvice on a ticklish subject, and then adhere strictly to the directions given.—By *J. T. Bartlett.*

## Moisture Absorption Through Varnish

IN experiments made by the Forest Products Laboratory, it was found that varnishes do not entirely prevent the transmission of moisture into wood but merely retard it, and that apparently there is no difference in moisture absorption through the coating due to the species of wood used.

The panels used in the experiments were of yellow birch, basswood, red gum, African mahogany, white ash, white pine, Sitka spruce, southern yellow pine, bald cypress, incense cedar, white oak, western yellow pine, Port Orford cedar, and sugar pine.

Three coats of high-grade spar varnish were applied to 4 panels of each species. Two panels of each species were brush-coated and two were dipped by a special dipping machine designed to secure an even coating. The panels were allowed to dry 72 hours between coats and 10 days after the final coat before they were given the moisture-resistance test.

The moisture-resistance test consisted in exposing the panels for 17 days to a humidity of 95/100 per cent, or in an atmosphere practically saturated with moisture.

At the end of this test, it was found that all the brush-coated panels had absorbed between 5 and 6.5 grams of moisture per square foot of surface, and the dipped panels between 4 and 5 grams.

# "It makes a difference"

THE kind of oil you use makes a difference in the efficiency of your motor. Havoline Oil forms a protecting film that will not break up. It keeps your motor running sweetly and at the minimum cost. Don't just ask for "oil"—ask for Havoline Oil, and in its sealed containers. It means health and long life for your automobile.

SONNEBORN PRODUCTS

# SAVE
## WHAT YOU HAVE

In many parts of your plant the dollars are slipping away due to preventable wear and tear.
Conserve! Protect! Stop deterioration! Avoid the expense of neglect. The replacement cost of every kind of building materials is high, so "save what you have".
Make a small investment while you are prosperous and save large expenditures later. Study this list of Sonneborn Conservation products —and decide where they should be used—now, in your plant.

### For Concrete Floors

LAPIDOLITH makes concrete floors dustproof, wearproof and non-absorbent.

Lapidolith is the liquid chemical which fuses the concrete into a granite-hard mass which cannot dust, or disintegrate even under heavy trucking.

70,000,000 square feet of concrete floors were lapidolized in the last two years.

Write for testimonials and sample of lapidolized concrete.

### For Wooden Floors

**LIGNOPHOL** preserves wooden floors and prevents splintering, rotting and wearing.

Treat new wooden floors with Lignophol —keep them new and resilient.

Old floors can be saved for years of service by this tonic wood filler.

### For Pipes

**PIPE ENAMELS** will withstand extremes of heat and cold without stripping or peeling. Not affected by chemical fumes. Furnished in colors to assist in pipe identification.

### For Walls and Ceilings

Cemcoat This mirror-like mill white multiplies the natural and artificial light by reflecting it from every angle.

Cemcoat furnishes more light in its cheapest form—reflected light.
This additional light is needed to speed up production and produce more profits.
Gloss Cemcoat for interiors. Flat Cemcoat for exteriors. Furnished white and in colors. Send for color card.

### For Roofs

**STORMTIGHT** is the asbestic coating which gives absolute protection to old or new roofs. Saves tearing up old roof and cost of new roof, also painting and repairs. Apply it to any roof surface.

### For Stacks

**BLACK STACK PAINT** protects the stack against extreme heat and from weather conditions. Used and recommended by leading plant owners.

### For Galvanized Surfaces

**GALVACOTE** adheres perfectly to any galvanized surface, overcoming the greasy film which causes ordinary paint to strip and peel.

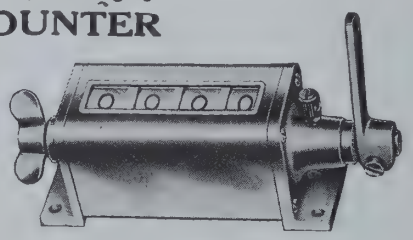
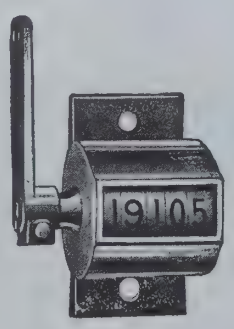
## His Own Boss–but Responsible

You can get results from the machine worker with less watching, less bossing, less friction in management relations. Cut down the *personal* supervision; supply the *mechanical* supervision of a production-recording

Veeder
COUNTER

*The large Set-Back Revolution Counter at right is ½ actual size. The small Revolution Counter below is illustrated nearly full size.*





The Set-Back Revolution Counter above records the output of machines where the revolution of a shaft registers an operation. Counts one for each revolution, and sets back to zero from any figure by turning knob once round. Supplied with from four to ten figure-wheels, according to purpose. Price, with four figures, as illustrated, $10.00 (subject to discount).

The Small Revolution Counter at left records the output of smaller machines where a shaft-revolution indicates an operation. Though small, this counter is very durable; its mechanism will stand a very high rate of speed, making it especially adapted to light, fast-running machines. Will subtract if run backward. Price, $2.00.

*Wherever you put a Veeder Counter you make a better-spirited worker. The counters go on practically every machine; the Veeder booklet shows the opportunities. Copy free.*

The Veeder Mfg. Co., 18 Sargeant St. Hartford, Conn.

## Botanical Notes from All Quarters of the Globe

By H. A. Gleason, Ph. D.

**A Newly Introduced Weed.**—The Japan honeysuckle, which has begun to run wild in the eastern and southern states in the past two or three decades, is an interesting example of a woody-stemmed weed, according to E. F. Andrews in *Torreya*. Formerly seen only in cultivation, it is now firmly established in woodlands and along stream borders in many localities, where it makes an almost impenetrable jungle with its tangled climbing stems and frequently smothers completely the plants which it covers. It trails on the ground when a support is not available, and it is suggested that in this habit it may have some economic value in preventing or reducing soil erosion.

**Blueberries in Cultivation.**—A tall species of blueberry which grows wild in the swamps of northern Florida has recently been introduced into cultivation through the efforts of Mr. M. A. Sapp of Pensacola, Florida. About 20 years ago Mr. Sapp selected 100 wild plants that were producing unusually good fruits and transplanted them to a cultivated and well-drained field. The plants thrived and fruited more abundantly than when growing in the natural habitat, and the fruit found a ready market at once. The plantation was enlarged until it now covers over eight acres. The annual yield is about 3,200 quarts per acre and the entire crop finds a ready sale at 10 to 12½ cents a quart. Several rather distinct types of plant in respect to habit of growth have been found and there is considerable variation in the quantity and quality of fruit produced by individual plants which gives opportunity for improvement by selection. The most desirable type for commercial culture is one that grows to a height of about eight feet and has a compact and freely branching habit of growth with fruit well distributed over the branches. The berries range from 10 to 14 mm. in diameter. The quality of the fruit is quite like that of the northern blueberry, which has also recently been domesticated and greatly improved.

**Vinifera Grapes in the Eastern States.**—Through recent experiences with vinifera grapes in California, horticulturists have learned that the failures of the early attempts to cultivate this grape in the East were due chiefly to the attacks of fungi, such as powdery mildew, downy mildew, and black rot, the serious injuries of a parasitic root-sucking louse called the *phylloxera*, and winter injury. It is now known that all these destructive agencies can be controlled. Actual demonstration of this has now been made at the Geneva Experiment Station, where for the past six years varieties of vinifera grapes have fruited satisfactorily. A report has already been published describing cultural requirements and methods of propagation, and giving a list of the most desirable varieties of table and wine grapes suitable for culture in New York State. Compared with the fruit of our native varieties these of vinifera are more solid, the skin adheres to the flesh, there is a higher sugar content, the flavor is richer, and the fruit keeps longer in storage. It appears certain that viticulture in the eastern United States is to be extended and greatly enriched in the future through the successful cultivation of pure and of hybrid strains of the European grape, the culture of which in the Mediterannean region dates from prehistoric time.

**Fictitious Botanists.**—Science deals with facts, but some supposed scientists are only a fiction! At least so Dr. J. H. Barnhart reports in a recent article in the Journal of the New York Botanical Garden. He finds that a well-known cyclopedia lists a number of such imaginary persons and discusses fourteen of them in detail. They are all described as Europeans, mostly of the eighteenth and early nineteenth centuries, who traveled extensively in what were then little-known regions of the two Americas, collected diligently, made important observations, and then returned to Europe to publish their discoveries in thick volumes with resounding titles. Dr. Barnhart infers that the same cyclopedia may contain other names equally fictitious.

**Origin of the Loganberry.**—It now appears that the plant that has recently become well known as the loganberry is a red-fruited variety of a trailing blackberry that grows wild on the Pacific coast, rather than a hybrid between this blackberry and a raspberry. Such is the view given by George M. Darrow in a recent Farmer's Bulletin from the Department of Agriculture. Mr. Darrow calls the plant the "Logan blackberry," in reality therefore a red-fruited blackberry. It is reported that this variety is distinguishable from certain black-fruited varieties only by the character (chiefly the color) of the fruit, and that there are also wild forms of the species which have red fruits. It is clear, however, that the original seedling of the Logan blackberry was grown from a seed taken from a black-fruited plant that grew in Judge Logan's garden. The Logan blackberry is found to be adapted to culture in the milder parts of the Pacific coast states. The variety does not thrive in any of the central or eastern states and thus far no strains adapted for culture in these states have been developed. Several forms of blackberries and blackberry-raspberry hybrids that closely resemble the Logan blackberry are also described.

**Is It Necessary to Fertilize an Apple Orchard?**—The answer to this question is being sought in the results of a carefully conducted experiment at the State Agricultural Experiment Station at Geneva, New York. The experiment has already been in progress twenty years, and the results to date have recently been reported in a bulletin from that station. Each year the same kind of fertilizer is applied to the individual plots on which five trees are growing and the results judged by comparing the yield and the size of the fruit and the tree growth with that of trees growing on unfertilized or check plots. The results of the first seven years of harvest have shown that the trees in this experiment would have been practically as well off had not an ounce of fertilizer been applied. During the later years the continuous applications of acid phosphate alone and of stable manure have continued to produce no noticeable increase of yield; potash and acid phosphate together have produced a slight increase in yield, but this has not been increased further by also adding nitrates. On the whole the differences in fertilized over unfertilized plots have been so slight that the use of any one kind of fertilizer or combination of them cannot be recommended. The use of fertilizers is hence found to be of doubtful profit for commercial orchards, at least during the first twenty years of the life of a cultivated orchard grown on a clay soil that is naturally rich in phosphorus and potash.

LEGAL NOTICES

PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

### Better Concrete

IN a series of tests at the University of Texas, specimens of concrete prepared with an excess of water showed a considerable reduction in strength, as compared with mixes in which only enough water was used to secure a concrete of workable consistency. Now in practical operation it is absolutely necessary to use enough excess water, over the minimum requirements of mixing, to make the concrete sufficiently fluid to be handled in wheelbarrows, carriages, etc., and so that it will flow readily into the form, and between and around the reinforcing steel. This means that an excess of water must be employed to place the concrete correctly and economically, and that this excess water materially reduces the strength of the concrete. The question arises whether something cannot be done to counteract this unfortunate effect.

To answer this Mr. G. A. Parkinson of the University staff made efforts to remove the excess water after the deposition of the concrete in the forms. If a pointed iron rod is forced into the concrete while it is still soft, he found that the excess water and likewise the entrapped air is permitted to escape upward, compacting the aggregate and increasing the density by some four per cent. This method of treatment has been called rodding; emphasis is placed upon the fact that while quite similar to spading, it differs materially from tamping.

Some of the results of the rodding tests are of great interest. The same procedure was gone through with fifty-four cylinders, six by twelve inches each, divided into three groups of eighteen each. In each group one cylinder was not rodded at all, one was rodded once, one twice, and so on until one was rodded seventeen times. In one of the three groups ten-minute intervals were allowed between successive roddings of a given cylinder; in the second group these intervals were increased to twenty minutes; and in the third to thirty minutes. In every case the first rodding was applied soon after the molds were filled, without waiting for the full interval assigned the series to elapse.

A single rodding, it may be necessary to state, does not mean a single thrust of one rod. It means the pushing of a rod into the concrete, to the full depth of the latter, once for every three square inches of surface area—or in the case of the test cylinders, ten times.

It is interesting to note that the maximum strength of rodded cylinders is about 130 per cent of that of the unrodded specimens. All three series acquired their maximum strength in about two or two and a half hours, though of course with different numbers of roddings. That is to say, for the 30-minute interval it required five roddings; for the 20-minute interval seven roddings; and for the 10-minute interval fourteen roddings, to attain maximum strength. It seems probable that the length of time and the number of roddings necessary vary with the temperature and with the percentage of water present in the first place.

The rodding was also tried with three groups of cylinders in which the mix contained, respectively, four, six and eight sacks of cement per cubic yard, while in the individual cylinders of each group the water content was varied. Comparing the results with the standard formulæ for the strength of plain concrete, formulated by Professor Abrams of the Lewis Institute, it appears that the effect of rodding is more beneficial with lean than with rich mixes, and that as might be expected it is more beneficial with wet than with dry mixes. Thus, the average strength of 8-sack concrete was increased only 45 per cent (approximately by rodding), and that of 6-sack mixes some 60 per cent; but with the very lean 4-sack mix the improvement was around 220 per cent.—*F. E. Giesecke.*

## St. Louis Needs Shoe Findings

ST. LOUIS, the largest shoe center in the world, lacks factories for the manufacture of shoe findings—such as laces, threads, shanks, hooks, nails, tacks, eyelets, buttons, heels, rubber heels, cloth linings, etc. These products must now be bought in the East. Most of the raw materials are shipped from the Mississippi Valley, manufactured in the East, and shipped back to the world's greatest shoe city—St. Louis.

The output of shoes in St. Louis this year will total approximately $175,000,000. The St. Louis shoe manufacturers spend more than $10,000,000 annually for shoe findings. A Mid-West factory in St. Louis could supply the trade here and economically reach all Mississippi Valley, South, Southwest, Middle West, and Far West markets from this central distribution point. Shoe findings is but one of the following sixteen industries St. Louis is seeking:

*Malleable iron castings*
*Farm implements*
*Rubber products*
*Screw machine products*
*Locomotive works*
*Blast furnaces*
*Cork products*
*Small hardware*
*Shoe laces and findings*
*Cotton spinning and textile mills*
*Dye stuffs*
*Steel and copper wire*
*Machine tools and tool machinery*
*Automobile accessories and parts*
*Drop forge plants*
*Tanneries and leather products*

Splendid St. Louis opportunities in these lines await enterprising men of practical experience and ample capital. The booklet, "St. Louis as a Manufacturing Center," will interest you. A letter will bring it. Address

*Director New Industries Bureau*

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to Correspondents are printed from time to time and will be mailed on request. Please write your queries; do not telephone them, please.

(14326) H. H. asks: A person born on Easter Sunday, April 21, 1889, when will his birthday fall on Easter Sunday again? A. The next time when Easter Sunday will fall on April 21st is in 1935, then in 1946, and in 1957. These are all the years of this century when Easter will occur on April 21st.

(14327) W. J. M. asks: I have had a problem bothering me for some time on which I should like to hear the opinion of anyone who thinks he has a solution. It is known that the sun has its heat replenished to a considerable degree by impacts of numerous meteorites upon it. As this process goes on, the sun is constantly growing larger, not appreciably but undeniably, by the addition of the masses of these falling bodies. This, which is true of the sun, is just as true of all other heavenly bodies. Furthermore, as these bodies grow larger by these additions, their attraction becomes greater and not only do the meteorites fall at increased speeds but more of them fall. It is apparent the universe as we know it could not exist for long in this state.

With what I have just said in mind, I see only two ways of accounting for the existence of the universe as we know it. Either the universe has been "condensing" throughout infinity from an infinitely fine gas to its present state with unit matter as its final goal or there is some agent at work to keep this from happening. If the first is true we have added another remarkable coincident to the already great number that we accept to explain the existence of the human race. If the second is true, the force which balances our universe must be of a very interesting nature, scientifically. The probabilities are very much against the first theory.

Can it be possible that a body can become so large that its own weight will cause the atoms at its center to be broken up into some basic material, such as that which we call ether, which will then filter out to recondense in the form of matter when conditions become such as to make it possible? A. Astronomers are agreed that the weight of meteors added to the earth or the sun in any moderate period of time such as a century is very small, too small to appreciably affect its mass. If there was such an effect it would cause a decrease in the size of the orbit of a planet and cause it to approach the sun. If as some think there may have been a more rapid accretion of meteors in remote past ages than this effect may have been experienced to a degree. You will find this topic treated at some length in Moulton's Introduction to Astronomy, which we will send you for $3.10.

(14328) K. C. A. asks: Please let me know method of filling a barometer tube so as to get complete vacuum and proper height of mercury column. A. Filling a barometer tube properly so as to include no air is not easy. The mercury should all be boiled in the tube. Put in not more than four inches and boil it by heating carefully and slowly over a flame. Herein lies the difficulty. If you do not heat quite a section of the tube, at least six inches it will break. Or if you heat the tube unequally it will suddenly break. Probably the experts heat the tube in a sand bath. When one section has been boiled to expel the air and has cooled another similar length may be filled and boiled as before. You will probably break several tubes in getting experience, but if you succeed you will have a barometer to be proud of. Usually amateurs take a wire with a small swab of absorbent cotton twisted in at the end and run this swab to the bottom of the tube. Then fill the tube with mecury and draw the swab slowly out. The cotton will bring with it nearly or perhaps quite all of the air in the mercury and on the glass in the tube. You should get much better than 29 inches at sea level with a barometer filled with the swab of cotton employed to draw out the air. You can get the correct reading of the barometer at the Weather Station in your place.

(14329) W. M. D. asks: Please tell me what the message from Mars was and where received, and when. I would like all information that I could get on Mars. A. There were certain sounds heard on the wireless apparatus which could not be made out. They were not words nor anything like our language. These disturbing noises were not explained by anyone. Some one suggested that they were signals sent from Mars. There is nothing more than that in this matter. It is very unlikely that any signals could be sent from Mars to the earth. We cannot now send half way around the earth, 12,000 miles. How could we send 35,000,000 miles to Mars? Nor have we any reason to think that the inhabitants of Mars, if there are any, would have the same language as our English speech. We could not talk with an inhabitant of Central Africa, how then with a Martian? There is little or nothing in the notion that signals have reached the earth from Mars.

(14330) F. H. M. asks: "What would be approximately the number of cubic feet air inhaled by a person during 8 hours' sleep? About what per cent of oxygen is used from the air by the body in breathing? Does air exhaled have greater specific gravity than air inhaled? Would such air have a tendency to settle to the floor of the room?" A. The average capacity of the human lungs is one gallon, or 231 cubic inches, but the average inhaled and exhaled at a breath is taken at about 30 cubic inches, thus the air is gradually changed in the lungs and their delicate surfaces are not exposed to the chill of air of a temperature much below their temperature. We may assume 15 breaths per minute as normal, and thus it may be calculated that we inhale about 375 cubic feet of air a day. This is vitiated with 4 per cent of carbon dioxide. This will vitiate 1,500 cubic feet of air to one per cent. This is *bad air*. If 4 parts in 10,000 of carbon dioxide are taken as the least to be permitted a man would require 37,500 feet of air each 24 hours. The oxygen removed from the air in 24 hours is enough to make the carbon dioxide. This may be calculated without difficulty. The exhaled air is hotter than the air of the room and thus at first rises. The carbon dioxide in it does not greatly increase its weight or density. Then, too, the carbon dioxide rapidly diffuses into the air of the room and will in time be found in all parts of the room.

(14331) V. T. S. asks: I had always been under the impression that June 21st was the longest day in the year. But according to the almanac, there are several days around the period of the Summer Solstice on which the elapsed time between sunrise and sunset is virtually the same. To put the question in another way: Is there any one day in June on which the sun at noon attains its highest possible point in the heavens? A. The longest daytime, that is, the time from sunrise to sunset, is about June 21st, but varies a little from year to year. The Summer Solstice is the moment when the sun is exactly at its highest north of the equator. The Vernal Equinox is the moment when the center of the sun is on the equator as it crosses it going north. These times are measured by the astronomer to a hundredth of a second. At the moment of the Summer Solstice the sun is highest in the heavens in any northern place, or, as it is better expressed, farthest north of the equator. The length of daytime as given in an almanac which only gives the minute of sunrise and sunset, neglecting seconds, will not vary for several days at that season, but if you had seconds and hundredths of seconds, there would be but one day when the time from sunrise to sunset was the longest. Now, why does not this occur always on the same day of the year, say, June 21st? That is because the time from January 1st to June 21st is not the same from year to year, while the time from the Vernal Equinox to the Summer Solstice is always the same. Every fourth year we insert an extra day in February which puts June 21st a whole day farther off from January 1st than it was the year previous, and this changes the relation of the almanac time to the astronomical events which do not vary as the calendar does. The answer to your question then is: There is a moment in June when the sun is highest in the heavens but that moment does not always fall on the same day of the calendar, although it is always at the same distance in time from the Vernal Equinox. A good almanac should give you the moment of the Vernal Equinox and of the Summer Solstice. These are respectively the time of the beginning of Spring and Summer.

A CAR equipped with a Harrison Radiator is a car that will give dependable and efficient engine cooling service—winter and summer. And the symmetry and beauty of the Hexagon Cellular construction of the Harrison Radiator enhances the appearance of any motor car. The Olds Motor Works is among the many representative automobile manufacturers who, in recognition of these facts, have adopted Harrison as their standard radiator.

# The Measure O' Men

In industry men are measured by their accomplishments. The yardstick of worth is work. Successful work done within the time set, at a reasonable cost, is possible only when light and sight are working together efficiently.

A poorly lighted factory is like a moving automobile with the brake on—its speed "drags." Unless your plant is correctly lighted, then there is a brake on your production—it "drags." Improve your lighting and you improve your production. Expressed in percentages, correct lighting will secure for you 12% more production, 25% less spoilage and 25% fewer accidents. Scores of tests covering a wide range of industry have determined the advantages.

You supply your workmen with the best tools, the most modern machines, because it pays. Yet if you partially blindfold your men by allowing them to operate in a poorly lighted factory, you have largely offset all of these advantages—and more. Remember that in nearly all industries the eye must guide the hand. Do not blindfold the eye.

Every form of industrial lighting problem has been met, studied and mastered by Benjamin Illuminating Engineers. Reflectors ranging in service from "all outdoors" to reflectors for lighting close-up bench work have been successfully designed and produced. Benjamin Industrial Lighting fits all factories. Full information will be gladly sent to industrial executives or their engineers, contractors or architects.

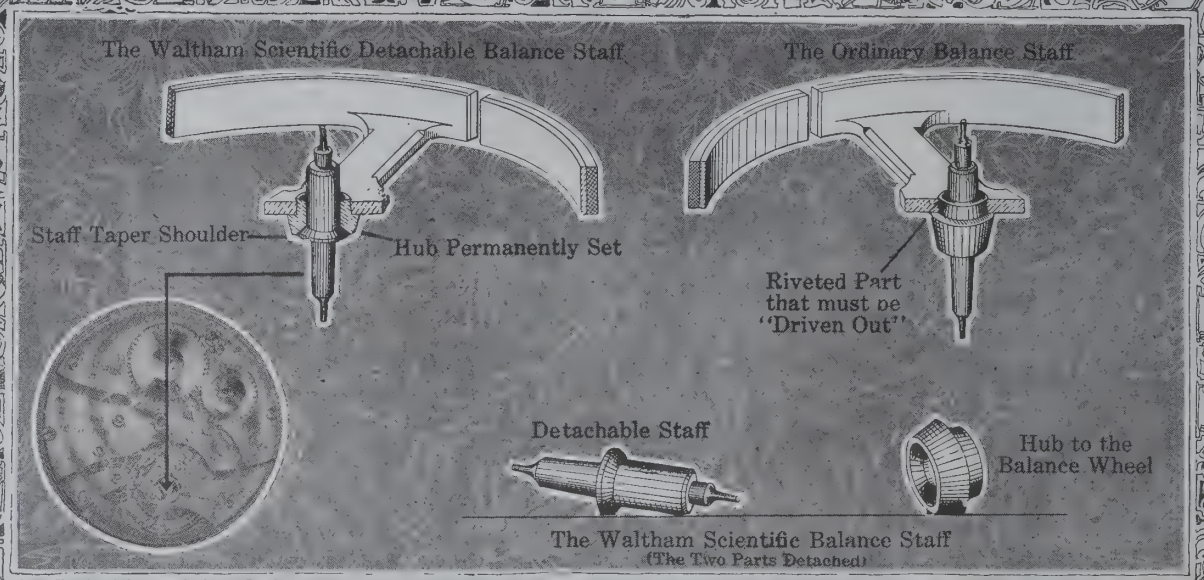
# PROOF



THE MOST SCIENTIFICALLY BUILT WATCH IN THE WORLD

## The Waltham Scientific "Detachable Balance Staff" that Means So Much to You in Time-keeping Accuracy

THE time-keeping accuracy of any watch depends absolutely upon the trueness (in the flat and round) of the Balance Wheel.

This trueness depends largely upon the mechanical precision with which the Balance Staff is riveted to the Balance Wheel.

In other words, if the Balance Staff is not firmly and truly located in its hub, the balance becomes eccentric or wobbly in its action, which immediately affects the time-keeping quality of the watch.

How important, then, is this exclusive development of the Waltham Scientific Detachable Balance Staff. Herein Waltham disregards the ordinary method of making the Balance Staff act as both axle and hub to the wheel.

You will note in the illustrations above that Waltham makes the Staff in two pieces. One a perfectly ground steel hub which is riveted to the Balance Wheel and is an integral part thereof. The Staff (you will note) has an accurately ground tapered shoulder which permits of its being driven to its exact seat and located accurately to the ground steel hub.

Any layman can understand that, if his watch is dropped or has a severe shock, the result will be a broken or bent Balance Staff, therefore requiring repairs in this important unit. Now a Staff which can be withdrawn easily from the hub without affecting the original, perfect assembly of the Balance Wheel assures him of continued accurate time-keeping and service from his watch.

On the other hand, when the ordinary Balance Staff is driven out of the Balance Arm for repair or replacement, the riveted part roughens and distorts the metal.

Therefore, the original aperture in the Balance Arm has been more or less destroyed, and when the new Staff is fitted, the watch repairer must rivet over enough of the metal to secure the Staff, which distorts the Balance Arm and throws the Balance Wheel out of true and poise.

The Waltham Scientific Balance Staff insures simplicity of repair and the original time-keeping quality of your watch.

This is yet another reason why your watch selection should be a Waltham.

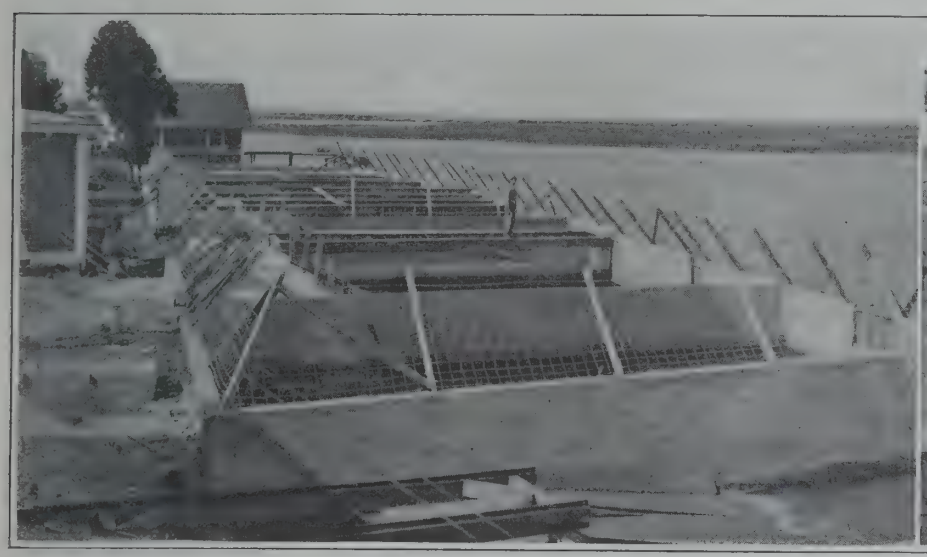
THE WEEKLY JOURNAL OF PRACTICAL INFORMATION

VOLUME CXXIII. NUMBER 2 ] NEW YORK, JULY 10, 1920 [ 15 CENTS A COPY $5.00 A YEAR



Pounds for the adult terrapin and a heated winter-house for the babies

Digging the baby turtles from the sand to put them in winter quarters

## Fish Fancying and Freak Farming

By George H. Dacy

ABILITY to appreciate and accept Opportunity when it presents itself often is the distinguishing attribute which centralizes the successes in one strata of society and the failures in another. Opportunity knocks at everyone's door at least once. The trouble is many of the residents are either not at home or else they are asleep when their chance for fame and fortune arrives. This is the simple story of a Southern townsman who did not need magnifying lenses in his glasses to see Opportunity when it came and who was on the front doorstep ready to welcome the honored guest.

About twenty years ago the Federal Bureau of Fisheries established an experiment station at Beaufort, North Carolina, and began investigations in terrapin raising under confinement. Naturally the townspeople were interested in Uncle Sam's freak fish farm. The doings of the scientists furnished plenty of food for local gossip while the fish ponds, the hatching beds and the winter-house for the young terrapin were interesting places to visit for recreation and amusement. Only one of the citizens, Dr. C. L. Duncan, apparently appreciated the commercial possibilities of domestic terrapin farming and he systematically set about to learn all he could about these aquatic turtles. For eleven years he studied the proposition and gained a first-hand knowledge of all the ins and outs of the fish-farming game. In 1913 he decided that he was equipped to embark in the business of raising terrapin on a commercial scale and as a consequence one of the most novel fish farms in the entire world has been established whereon at present more than 30,000 terrapin a year are being raised.

Years ago wild terrapin inhabited the salt and brackish marshes along the Atlantic seaboard in large numbers and were highly relished and prized by epicures. These palatable turtles have so grown in popularity that they now have come to be regarded as one of the greatest delicacies known to connoisseurs and the demand for them has led to such persistent overfishing that a marked diminution in the available supply has resulted. The result is that Chesapeake terrapin which measure six inches in length on the lower shell now sell for $50 to $60 per dozen on the city market while larger terrapin are correspondingly more valuable. Louisiana and Texas terrapin are almost as highly prized as are the Chesapeake variety while the Carolina and Florida species are not in demand for table use. The National Bureau of Fisheries has irrefutably demonstrated that terrapin farming may be practically and profitably engaged in on a commercial scale while the experiences of Dr. Duncan and a resident of Savannah, Georgia, who also has attempted this freak farming business, are staunch endorsements of the findings of Uncle Sam's fishing experts.

Doctor Duncan's fish farm covers about two acres of marshland close to the coast and is inclosed by a concrete and wooden wall and fence wherein the 2,000 odd adult terrapin can live comfortably, be fed and supplied with safe quarters for laying their eggs. Separate inclosures are provided for the young terrapin while winter quarters for the youngsters are provided in the way of an artificially heated house which is maintained at a temperature of 80 degrees Fahrenheit during cold weather when the turtles under natural conditions are accustomed to hibernate. Under natural conditions the young terrapin are hatched just about the time when the hibernation season is beginning. The consequence is that the young begin a long siesta as soon as they are able to waddle about. During their winter sleep, the baby turtles live on masses of egg yolk which are inclosed in their stomachs. They emerge from their mud holes the next spring much weaker, smaller and less vigorous than when they were born. On the other hand, the young which are housed in the heated quarters do not hibernate during the winter but feed voraciously and develop rapidly so that the following spring they are as large as two- or three-year-old terrapin which have developed out-of-doors. For commercial production of market terrapin, the hothouse method of forcing the turtles to early and economical maturity is most successful.

Terrapin mature and attain full development at the age of six to seven years. The males are only about two-thirds as large as the females and hence are less valuable for market purposes, selling for only $1 to $1.25 apiece. The mating is promiscuous, there usually being about twice as many females as males in the average colony. As a rule, it requires from eight to nine weeks for the eggs to hatch, the average female producing about fifteen young a year. Terrapin are notorious as being the worst mothers in the world as they abandon their young and never take any interest in the progeny after the eggs are laid. When ready to deposit her eggs, the female terrapin scoops a jug-shaped hole in the sand with her hind feet and therein buries her eggs. Then she replaces and packs the sand in place and as far as possible conceals the location of the egg nest. She then leaves the eggs to

Female terrapin six inches long and worth from $50 to $60; a male of smaller size and less value, as is usual; and a collection of eggs with the newly hatched young

## The $5,000 Einstein Essay Contest

IN January, 1909, an anonymous donor who was interested in the spread of correct scientific ideas offered through the SCIENTIFIC AMERICAN a prize of $500 for the best essay explaining, in simple non-technical language, that paradise of mathematicians and bugaboo of plain ordinary folk—the fourth dimension. Many essays were submitted in this competition, and in addition to that of the winner some twenty were adjudged worthy of ultimate publication. It was felt that the competition had added distinctly to the popular understanding of this significant subject; that it had done much to clear up popular misconception of just what the mathematician means when he talks of four or even more dimensions; and that it had therefore been as successful as it was unusual in character.

Today, after a lapse of eleven years, we have with us a freshly-risen scientific topic of transcendent importance—one which has occupied a place in the public prints and the public mind such as has never before been granted to any matter of abstruse scientific doctrine—and one which actually depends in large measure upon the very concept of extra-dimensionality which was so ably treated by the contestants for the prize of 1909. We refer, of course, to what for want of a better name must still be called the Einstein Theory of Relativity, but which possesses such universal bearings that it really cries out for a name less suggestive of controversy and narrow bounds. Every person of intelligence wants to know about this theory; and it is highly important that every person of intelligence know something about it. Numerous efforts have been made during the past six months to present it to the non-mathematician—some conspicuous failures, others successful in greater or less degree. By no means has the success of these efforts been in direct ratio with the distinguished position of the scientists making them. It is felt in all quarters that much remains to be done in this direction; and the SCIENTIFIC AMERICAN is of the opinion that a direct stimulus for further effort to make intelligible to the mass of educated people what Einstein has done is distinctly in order.

In view of the connection of the SCIENTIFIC AMERICAN with the previous prize contest, anticipating in more ways than one the event which we have now to announce, it gives us the greatest pleasure to state that Mr. Eugene Higgins, an American resident of Paris and for many years a close friend of this paper, offers through the SCIENTIFIC AMERICAN a prize of Five Thousand Dollars for the best essay on the Einstein postulates and their consequences, written so that a person of no special mathematical training may read it profitably. Mr. Higgins has followed in the footsteps of the anonymous donor of 1909 by leaving the entire contest in the hands of the SCIENTIFIC AMERICAN. He has deviated so widely from precedent in the amount of the prize with the purpose of attracting to the contest men of the very highest caliber, thereby making the event an unqualified success. This we are sure it will be. The sum of five thousand dollars exceeds, if we are not mistaken, any award open to a professional man with the single exception of the Nobel prize, for which he cannot specifically compete. The prize is very likely to exceed the annual salary of the winner, and is certain to amount to a very handsome proportion of that salary.

In order that prospective contestants may have every possible advantage of time in which to work up their material, we are announcing the contest at once, not waiting until the Committee of Judges shall have been selected. As in the contest of 1909, this committee will be a body outside our editorial staff, having no immediate connection with the SCIENTIFIC AMERICAN, so that they may be selected with sole reference to their eminent fitness to serve. It need not be pointed out that they will necessarily be men who will give up reasonably good prospects as contestants in order to contribute to the success of the event as judges.

The rules under which the contest will be conducted are displayed on the opposite page, and will be reprinted from time to time in later issues. It is earnestly hoped that Mr. Higgins' more-than-liberal offer will bring forth a more-than-liberal response, and that his intention of inspiring the writing of essays which shall really illuminate Dr. Einstein's system will be amply realized. We have tried to do our part toward this consummation by making the conditions as liberal as possible. We leave the issue in the hands of the competitors.

## The Water Power Bill

THE signing by the President of the water power bill is the first step toward the development of the abundant natural water power of the United States. It would not be easy to find a great national enterprise of a physical character, which has been made the subject of more painstaking consideration, and the bill as now signed represents the experience and considered judgment of some of the best minds in the country. Particularly gratifying is the fact that the law will harmonize hitherto conflicting elements; for while it carefully protects the interests of the people of the country at large, its terms are sufficiently liberal to attract the large amount of capital which will be necessary to render our natural water powers available for industry and commerce.

Under the new law, all water powers over which the United States Government has jurisdiction will be controlled by a Water Power Commission, composed of the Secretaries of War, Agriculture and the Interior. Licenses for the development of power will run for fifty years. The amount which the licensee must pay for the use of the water power is fixed by the Commission, and the price to be paid by the consumer is fixed jointly by the Commission and the State Commission, or, in cases where a local agency does not exist, by the Federal Commission.

When the license expires, the United States has the right to take over and operate the property upon the payment of an amount which shall not exceed the original cost. Licenses issued to private or corporate applicants will be subject to annual charges, fixed by the Commission for the following purposes: first, covering the cost of the administration of the Act; second, recompensing the United States for the use of its lands; third, absorbing any excess profits that may be earned by the licensees. One-half of the charges collected on account of public lands is to be paid into the Reclamation Fund, three-eighths to the States and one-eighth into the United States Treasury.

Of the charges collected on account of licenses on navigable rivers, one-half is to be reserved as a special fund to be spent by the Secretary of War in the maintenance of locks and for the construction of head-water improvements on navigable rivers. The remaining half is to be paid into the Treasury.

We recently dwelt in these columns upon the great economic advantages of the electrification of our railroad systems, a large proportion of whose freight consists of coal which is hauled for the operation of their steam locomotives. By removing the hindrances to water power development, the water power bill will prove a most active agent in bringing about the electrification of our railroads, to say nothing of a greatly increased substitution of central electric power stations, with long distance transmission, for many of the unrelated and widely scattered steampower plants, big and little, as they exist today.

## The Era of the Eighteen-Inch Gun

ALTHOUGH there is not as yet an 18-inch gun afloat in our Navy, there is reason to believe that already the adoption of the eighteen-inch gun is contemplated by the Bureau of Ordnance. If so, we shall probably have a renewal of the old controversy between the advocates of great volume as against great weight of fire, such as more than once has stirred up no little tempest on the calm waters of bureaucratic procedure and found an echo in the outside civilian world.

The contention that the discharge of a large volume of projectiles of moderate weight is more effective than that of a smaller number of much greater weight and power, is as old as the history of the rifled gun. The question was hotly debated when we moved up from the twelve-inch to the fourteen-inch gun, and again when we discarded the fourteen-inch for the sixteen-inch gun; and it is certain that, if the tests of the new naval eighteen-inch gun should be satisfactory, the question will once more be threshed out along the old lines.

If the eighteen-inch gun should be adopted, it will probably be placed on some of our new 43,000-ton battleships. As designed, they were to carry twelve 50-caliber sixteen-inch guns, which means that on the same displacement and with the same speed, fuel supplies and general accommodations, they will be able to mount only eight eighteen-inch guns, particularly if the new pieces are to be of 50-caliber length. Many people will be surprised that a reduction of fifty per cent in the number of guns should be necessary when the caliber is increased only about twelve per cent, but this is because the weights of guns and projectiles increase approximately as the cube of the diameter. This applies not merely to the rifle itself, but it affects also the weight of the mount and the loading mechanism, the total weight of projectiles in the magazines, and so forth.

In favor of an eighteen-inch gun are the following points: The gun is more accurate; its range and energy are much greater; the bursting charge also is greatly increased, and therefore the destructive effect, when penetration of armor has been effected, is far greater.

The disadvantages are that not only is the number of shells delivered in a single salvo thirty per cent less for the eight-gun battery, but because of the greater weight both of gun and ammunition, the rate of fire is slowed down, so that the total number of projectiles delivered in a given time against the enemy is considerably over thirty per cent less than that delivered from the twelve-gun ship.

Now, bearing in mind the common saying aboard ship that it is the shells which hit that count, it can be seen that there is over a fifty per cent better chance of landing on the enemy with a twelve-gun "Indiana" than there would be with an eight-gun "Massachusetts." The sixteen-inch shell weighs 2,100 pounds, and if we aim at the highest velocities and make our eighteen-inch gun fifty calibers in length, the weight of its projectile will probably be about 3,000 pounds, a fifty per cent increase in weight which must necessarily slow down the speed of handling. The only eighteen-inch gun afloat is the big fellow which the British built for the 32-knot cruiser "Furious," but subsequently mounted on a monitor and used in the bombardment of Zeebrugge. With a view to extending the life of the gun, the British used a heavy projectile weighing 3,600 pounds and having a moderate velocity.

Despatches from Washington state that 18-inch guns are to be used on two of the new battle-cruisers. If so, one turret and a pair of guns would have to be dropped, leaving these ships with six eighteen-inch guns in two-gun turrets, which would be an arrangement similar to that on the battle-cruisers "Repulse" and "Renown," which mount six fifteen-inch guns in three turrets.

If the eighteen-inch gun is to be adopted because of its superior range, it will be possible to utilize it at the longest ranges only in combination with airplane spotting and to make sure of spotting from a point above the enemy's ships, it is necessary that the attacking ship be accompanied by a fleet of fighting machines, sufficiently powerful to insure absolute superiority in the air.

## Electricity

**An Electric Atomizer.**—There has recently been placed on the market an electric atomizer which is suitable for use in hospitals, schools, sickrooms, and in a variety of other places. It is suitable for sweetening cellars or ice boxes when formaldehyde is added to the water in the atomizer. The atomizer consists of a small brass bowl which contains a heating element imbedded in insulating material. The apparatus is mounted on a wooden base and is supplied with a cord and suitable attachment plug. In use, the bowl is filled with water and a few drops of perfume or disinfectant are added as desired. The boiling of the water drives off the liquid in the form of vapor, thus humidifying, perfuming or disinfecting the room.

**Hydroelectric Development in Texas.** — More than $4,000,000 is to be expended in the construction of a hydroelectric plant which is under way near Eastland, Texas. Preliminary work upon the project is well advanced. It consists of the construction of a dam across the Leon River about four miles south of Eastland which, when finished, will impound more than 600,000,000 gallons of water and serve as the source of the initial power for generating electricity that is to be distributed throughout that part of Texas by means of transmission lines. One of the chief purposes of the company building this power plant is to furnish electric power for drilling and pumping oil wells in the Central-West Texas fields. It will also provide industries and towns with electrical energy.

**Long Distance Transmission Lines.**—According to a French engineer writing in *Revue generale de l'Electricité*, distances of 400 to 500 miles can be spanned with a transmission line by making use of the so-called "quarter-wave" construction. Such a line has the usual two conductors for single phase and three for three-phase, but frequency, capacity and inductance have such values that at no load the line is in resonance. The current must be maintained nearly constant at the generating end, and constant voltage will be received at the other, with reasonable regulation, efficiency and conductor cost.

**A Rotating Arc Lamp.**—A French inventor has recently worked out a rotating arc lamp in order to approximate as closely as possible the theoretical point source of light, fully utilized and automatically maintained. His arc lamp uses a cored carbon rod of much the ordinary type as positive electrode, which provides the luminous crater. The non-luminous negative electrode is a metallic ring surrounding and presenting its inner edge toward the crater; the ring is cooled by circulating water or spirit. By the action of the magnetic field of a coil the arc between the crater and the inner edge of the ring is caused to rotate at 500 to 3,000 revolutions per minute. The rotation is too rapid to be distinguished by the eye, and the arc only appears as a highly incandescent spot surrounded by a bluish halo. Only the positive electrode burns away and need be moved; this regulation is controlled by the dilation of a metal strip, and is independent of the arc current and voltage.

**French World-Wide Radio Scheme.**—There is being discussed in France a scheme for embracing the whole globe with stations erected wholly on French territory. To overcome difficulties due to atmospherics, experts believe that it will be necessary to use at least 1,500 kilowatts and to employ antennæ at least 1,500 feet in height. The network of stations proposed would comprise the stations at Tahiti, New Caledonia, Indo-China, Djibouti, and France. The center of the net work is in France, and comprises three stations able to communicate respectively with (1) the United States, (2) Martinique and Brazil, (3) West Africa.

## Science

**The British Association for the Advancement of Science** will hold its next meeting at Cardiff on August 24-28 next, under the presidency of Prof. W. A. Herdman, of Liverpool University. The inaugural address of the president will comprise a general survey of oceanography and a detailed discussion of certain problems, especially relating to sea fisheries.

**U. S. Government Maps.**—At a conference held in Washington last September by representatives of fourteen map-making organizations of the Federal Government and ten national scientific and engineering societies, several recommendations were made concerning future work of this character by the Government. It is proposed to appoint a permanent Board of Surveys and Maps to act as an advisory body, and to establish a central information office concerning mapping, preferably in the Geological Survey. Several other suggestions were made looking to coördination of work, but the conference reached the conclusion "that there is little actual duplication of effort materially affecting the progress of mapping the United States." It is estimated that the work of primary control, which is in the hands of the Coast and Geodetic Survey, can be completed by 1933 at a cost of $6,305,000, and that the topographic map, which is in charge of the Geological Survey, can be completed within the same period for $40,490,000 (including coöperative appropriations by states).

**The Latest Bull.**—That a little knowledge is a dangerous thing is made again clear by a reporter for a New York daily who was given the assignment of writing a couple of columns about Einstein, when this topic was still new, back in December. The bright young man went along swimmingly for a while, giving a very intelligible account of the predicted deviation of light passing near the sun, and the manner of making observations for this deviation during total eclipse. Then he went on to state that the Einstein doctrine was remarkably borne out, since not alone was the expected deviation observed, but Einstein was found to have accurately predicted its *time*—1¾ seconds!

## CONDITIONS FOR THE $5,000 PRIZE ESSAY CONTEST

1. No essay shall be longer than 3,000 words.

2. All essays must be in English, and written as simply, lucidly and non-technically as possible.

3. Each essay must be typewritten, and identified with a pseudonym. The essay shall bear a title and the author's pseudonym *only*, and must be enclosed in a plain sealed envelope likewise bearing this pseudonym. In the same package with the essay must be sent a second plain sealed envelope, also labelled with the pseudonym, and containing a statement of the name and address of the contestant, the pseudonym used, and the title of the essay. It is necessary to follow these instructions implicitly, in order to guard against confusion in opening the envelopes and assigning the pseudonyms to their proprietors, especially in view of the possibility that two of the contestants may employ the same pseudonym. The envelopes should be sent in a single package to the Einstein Prize Essay Editor, SCIENTIFIC AMERICAN, 233 Broadway, New York.

4. All essays must be in the office of the SCIENTIFIC AMERICAN by November 1st, 1920.

5. The Editor of the SCIENTIFIC AMERICAN will retain the small sealed envelopes containing the competitors' names and addresses, which will not be opened until the competitive essays have been passed upon and the winning essay selected.

6. As soon as the judges have selected the winning essay, they will notify the Editor, who will open the envelope bearing the proper pseudonym and revealing the competitor's true name. The competitor will at once be notified that he has won, and his essay will be published in an early issue of the SCIENTIFIC AMERICAN.

7. There shall be but one prize, of FIVE THOUSAND DOLLARS, to go to the author of the best essay submitted; but the right is reserved to divide the prize between two contestants if in the opinion of the judges the best two essays are of equal merit.

8. The SCIENTIFIC AMERICAN reserves the right to publish in its columns, or in those of the SCIENTIFIC AMERICAN MONTHLY, or in book form, any of the essays which may be deemed worthy of this. Aside from such rights, the essays shall remain the properties of their authors; but no manuscripts can be returned.

9. The number and personnel of the Committee of Judges will be announced in an early issue.

## Aeronautics

**For Our Aviation Service.**—Appropriation of $60,000,000 for army aviation in 1921 has been recommended to the House Military Committee by Major-General Charles T. Menoher, Director of Air Service, $23,714,000 to be used for production and purchase of airplanes and $750,000 for balloons, airships and lighter-than-air machines in general.

**Aerial Licenses.**—The proper licensing of craft and pilots and airdromes is the first essential and has been adopted in all the allied countries, so there will be plenty of sound precedent to work upon. Legislation making illegal low flying and stunting and the dropping of advertising pamphlets must be put through without delay. Rules of the air roads, of entry and exit from airdromes, of lighting, et cetera, must also come up for consideration. The international air laws laid down at the Paris convention are practically drawn from the flying laws originally made for Great Britain and which were adopted by the nations who signed the agreement. American air conditions differ very slightly from those of other countries, and the international model will be found very comprehensive.

**Ford's Aviation Activities.** — The news that the Ford Motor Company proposes to build airplanes is not startling. It has been announced many times. But the powers of the new Ford Company permit it to manufacture aircraft. In this connection, it is perhaps worth mentioning that the Ford Company recently purchased in England the entire outfit and works of one of the largest airplane producers in Great Britain. The airplane has not yet reached that state of scientific perfection which permits of its being automatically thrown together by the mass production method. If, on the other hand, Mr. Ford were able to produce an all-metal plane for, let us say, $1,250 and produce them in large numbers scientifically, the boom in aerial "flivvers" would probably be great. However, with the force at his command and the interests he controls, Mr. Ford would be doing a real service to humanity in general, and to America in particular if he were able to produce rigid airships by mass production.

**Why Not Fireproof Tanks?**—Is it not time that all aircraft were fitted with fireproof gasoline tanks in this country? Would it not be rendering the greatest possible service to aviation to insist upon their use? Our air authorities appear to be strangely blind to the fact that if you want public money for promotion of flying, it is necessary to obtain public belief and confidence in the resources of the air. In flying, as in all other forms of transport, fire is the most terrible risk. It very rarely occurs except in a crash or a bad landing. If the gasoline tank is of the ordinary kind that bursts upon hitting the ground, fire is almost certain. But the air authorities know that there are fireproof tanks which have proved sound after most exhaustive tests—so much so that practically all British machines were fitted with them at the close of hostilities. All civil machines should be fitted with them at once.

**A Flying Academy.**—When the American flying service really gets into going order, serious consideration will have to be given to the establishment of an academy similar in type and standing to the military and naval colleges at West Point and at Annapolis. Since it is certain that in a few years' time the flying service will be of equal importance if not of more importance than the other services, an air college from which men may be commissioned direct into the service after strenuous tests will become a necessity. The practical interest already taken in aviation by the big educational institutions promises well for the future.

# The Twentieth-Century Lumber-Jack

## Some of the Machines and Methods Which Were Not at the Disposal of His Grandfather

By J. F. Springer

*LUMBER! That is the question of the hour—and a grave one. For decades these United States enjoyed the finest and most expansive forests to be found in any part of the world; and that very abundance made us careless with regard to our lumber industry. We kept on cutting trees with little thought about the future. Our reforestation plans were on too small a scale. And the inevitable has come to pass: we are facing an early lumber famine, unless drastic measures are put into execution at once. This article deals with the improved methods of logging. Another article will deal with the lumber shortage. Still others will appear from time to time bearing on the lumber industry.*—THE EDITOR.

LOGGING is, naturally, one of the old lines of activity. It is also one of the highly modern ones. Its procedure has undergone various changes, so that the practice followed at present in certain leading centers of activity would probably astonish the old experts if they could now view the happenings from beginning to end. These old fellows would doubtless be gratified to learn that with all the great advances in machinery two of the oldest of all hand-tools are still leading devices in the lumberman's art. These are the wedge and the axe. The cross-cut saw has taken over some of the duties of the axe, but the latter tool is still indispensable. Trees are felled with the axe alone, or with the axe and the cross-cut saw, the wedge being employed as an auxiliary. It will perhaps surprise many to learn that there has apparently been invented no power-driven machine for felling trees that has secured any widespread commercial application in logging. Probably the difficulty in designing such a machine centers not so much upon making it successful in the actual felling as in the matter of easy portability. The tree may stand in the midst of brush and undergrowth, or upon uneven ground or far distant from a considerable road, and in consequence be difficult of access for a mechanical device and for the power unit to drive it. The axe, wedge and cross-cut saw can go wherever the men can go, and this is one great reason, no doubt, for their continued popularity.

A good deal of change has come over modern logging in connection with getting the logs from the place where the trees are felled to the principal avenues by which they are transported to the mill. Here the cable-way has come into large use. Instead of dragging or sliding the logs along on skidways or the like, they are hoisted into the air and carried along clear of brush, old logs and uneven topography. But while cable-ways have invaded a part of the transportation field, this is not to be understood as meaning that the older procedures have been altogether displaced. By no means. There are situations, and many of them, where the cable-way is not so easy to install and others where it could hardly be installed at all.

As to transportation to the mill, the waterway is still employed; but in Michigan, Washington, the South and elsewhere, there are numerous logging areas where there is no adequate and convenient stream. New England conditions do not, by any means, generally obtain in the logging regions of the United States. The logging railroad is now in considerable evidence. Then with the development of the motor tractor, this device has come into use. In short, there are many situations now where instead of the logs being rafted and floated individually along, they are being hauled in trains, either by locomotives and tractors or else by mules, horses or oxen.

**A typical lumbering scene from Washington, with donkey engine and cableways**

The felling of any tree is an interesting operation. This is pre-eminently the case when the tree happens to be a giant of the Pacific coast—a big sugar-wood, spruce, Douglas fir or redwood. A great notch is made on the side of the tree selected as looking more or less directly in the direction desired for the fall. It is placed a little above the swelling due to the roots. This notch may be wedge-shaped, with the two surfaces at an angle of about 45 degrees and the under surface horizontal. The notch has two possible functions. One is to direct the fall and the other is to prevent bad splitting of the bole. Sometimes the tree naturally leans in the direction of fall. But at other times this is not at all the case. A smaller notch than the size ordinarily used is then employed (unless the axe is to finish the job), contrary to what one might expect. The reason centers on the use of wedges. These are used with more effect, it seems, when the notch is comparatively small. The actual felling of the tree is effected from the side opposite to the notch. Where the old method of doing the felling with the axe is to be employed, the notch on the opposite side is to anticipate this use and to be made very deep in consequence. In fact the cuts penetrate past the center of the hole. Here is a marked distinction between the older and the newer practises. With the latter, the felling is done with the cross-cut saw and wedges. The notch on the side on which the tree is to fall is greatly reduced in depth, the penetration being often less than half a radius. This means a very great reduction in the amount of wood that has to be removed from the notch. On the opposite side all the work is done by the axe and the wedges. Work with the axe is, for the whole job, enormously cut down as compared with felling by the axe. Even in the matter of the notch the horizontal cut may be made with the cross-cut saw, the axe being used for the slanting cut only. While the inclined cut is ordinarily made above the horizontal one, this is not at all necessary. Thus, it may be very desirable to save as much of the bole as possible. Under this condition the slanting cut with the axe may be made underneath. The reader who has carefully followed the foregoing will have no trouble, perhaps, in seeing that the axe is coming to take only a small part in the cutting down of the great trees of the forest. Its duty may be confined only to a slanting cut reaching in less than half a radius.

Assuming that a small notch has been made with a view to felling by saw and wedge, the saw is started on the opposite side of the bole a few inches higher up than the horizontal surface of the notch. The saw is operated horizontally. After a while it will have completely buried itself. As it goes on into the body of the bole, wedges will after a little become usable.

**Old and new types of anchors and how they are tested to determine their fitness for sea duty**

## Is the Anchor Safe?

**By Paul Harnden**

THE ship's anchor, from the standpoint of safety, is a very important piece of equipment. Before an anchor is accepted for any of our great sea-going vessels it must pass severe tests and a rigid examination both by the manufacturer and by Lloyd's and the American Bureau of Shipping.

Since most of our anchors are of cast steel, the designer must be careful that all junctions of metal are of uniform thickness, to avoid cooling strains in the metal. The modern stockless anchor consists of only two principal parts, a shank and a head. The head is movable on the shank and has two wide spoon-shaped flukes, which are depended upon for gripping power. Since the head must bear most of the strain it is most thoroughly tested.

After the head has been cast and annealed it is given a "dropping test." It is lifted about ten feet above the ground by a crane and dropped on two solid pieces of iron. This is to guard against fracture when the anchor is dropped to the bottom at sea. It sometimes happens that the anchor is broken in two when it is dropped on "hard" or rock bottom. All parts of the anchor are carefully inspected before assembly, even to the pins which lock the parts together. After complete assembly the anchor is given a final "pulling test." In this test the flukes are dropped into a depression in the floor, a chain is attached and a hydraulic machine delivers a measured pull several times greater than the anchor will ever have to resist in actual use. If the anchor is found flawless after this test it is passed, ready for use at sea.

Manufacturers have devised other tests for their products, some of which are even more severe. One test, by which it was attempted to show just how the anchor acts on the sea bottom, is shown here.

The assembled anchor was dropped a distance of twenty feet onto hard slag and then was dragged along frozen ground (hard bottom) for a distance of twenty-five feet. Here the flukes found a soft spot and "dug in," with the result that continued power applied by the pulling engine caused the anchor to lift bodily between four and five tons of frozen earth.

The largest "stock anchor" made is the 10,000 pound size, shown in the photograph. The largest vessels, however, require anchors three times this size, and these must be "made to order."

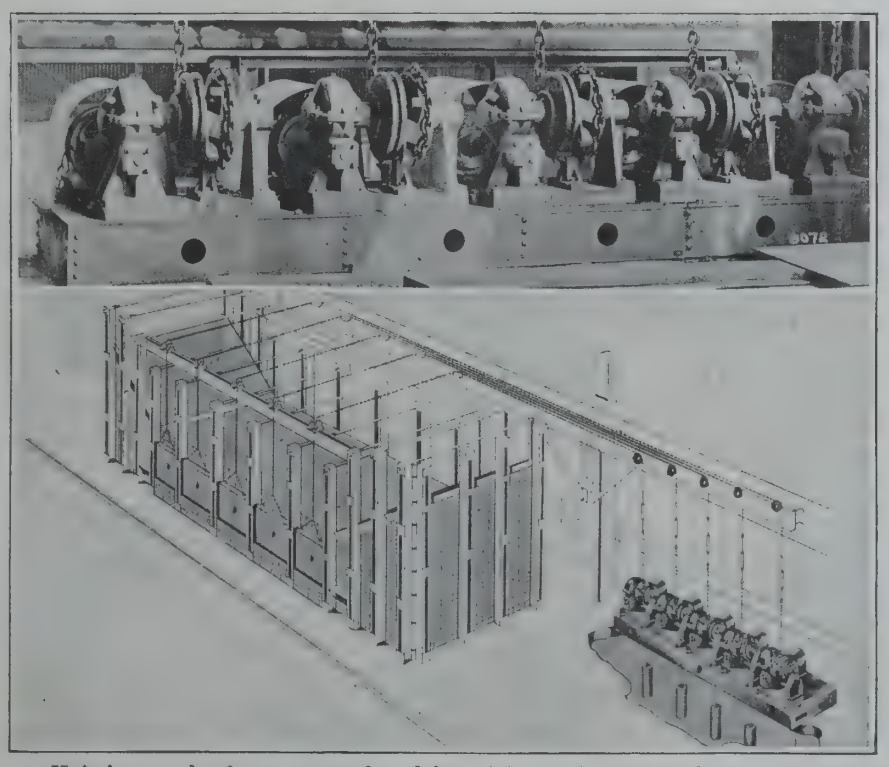
It is interesting to note that the old familiar navy-type of anchor is still being made. It is used chiefly on pleasure yachts and sailing vessels, where it adds a picturesque touch.

The manufacture of anchor chain is of no less importance than the making of the anchor, because the anchor would be worthless without a good chain. Until the last two years all anchor chain was forged and it was considered impossible to cast it successfully. Difficulties of manufacture have been overcome, however, and a large part of the anchor chain used on our new merchant marine is of cast steel. Its makers subject this chain to a more severe test than is required of forged chain and it is claimed the cast chain is much stronger. The chain is subject to a pulling test, as is the anchor before final acceptance.

## Electrification in Europe

THE electrification of the German-Austrian West Railroad, according to the statement of the Under-Secretary of State, Dr. Ellenbogen, will be possible in about three years. This will mean a saving of about three million tons of coal. The stretch in Voralberg will derive power from the Lüna Sea, while that from Wörgl to Arlberg will be fed with electricity generated in the Achen Sea; the improvement of electrical stations in Salzburg and Karpun will furnish power for the section from Salzburg to Wörgl and Salzburg to Linz; that from Linz to Vienna will receive electricity through the harnessing of several different sources of water power.

There has been created in Warsaw, to study the electrification of the main railroads in Poland, a commission whose duty it shall be to collect data concerning present steam locomotives in Poland, electric railroads and larger electrical undertakings in foreign countries, data concerning the advantages arising from electric railroads, under what conditions they work and the reason for their introduction. The commission shall render an opinion, on the basis of this material, whether and to how great an extent the railroads of Poland should be electrified.



**Hoisting mechanism now employed for raising and lowering doors of open hearth and heating furnaces**

## Handling the Heating-Furnace Doors

**By Jules Gaudel**

DEVELOPMENT of a fool-proof automatic system for raising and lowering heavy doors on open hearth and heating furnace work has been recently announced by a large machinery firm of Chicago, after the first installation in a steel plant in Conshohocken, Pa., which has been in continuous operation for fourteen months. Doors operated by this method, it has been demonstrated, always go up to the proper position, and always go down to the proper position, no matter what their weight may be.

Five hoists with an automatic release are used. On each hoist is mounted a pair of chain sheaves, attached to a worm wheel shaft between two flanges, which are pinned to the shaft and supplied with fiber friction surfaces on the sides toward the sheaves. The worm wheel is driven by a worm mounted on the shaft of a reversible motor, the worm and wheel being enclosed in suitable housing.

To raise the furnace door the motor is started in the direction which will pull down on the left-hand chain. As long as the counterweight continues its pull, the sheaves squeeze out against the flanges, and are thereby driven in the direction which will wind up the left-hand chain, and thus lift the door.

The right-hand sheave has a fixed stop on its periphery, so located that it will come in contact with a stop on the bottom casting when the furnace door has reached its proper height. With the motion of the right-hand sheave arrested by this stop, the shaft cannot rotate the left-hand sheave farther because the squeeze between the sheaves and friction flanges are relieved. There is no opportunity, therefore, for overwinding, and if through carelessness the current is not shut off promptly, the shaft with its flanges will simply continue to revolve in a sliding frictional contact with the sheaves, but without the power to grip and rotate them further.

For lowering the doors the direction of the motor is reversed, and practically the same process repeated, except that in this case the power of the motor is used to lift the counterweight, while the pull from the weight of the door serves to keep the sheaves squeezed apart against the friction flanges until a stop on the left-hand sheave engages with a stop in the bottom casting, and prevents overwinding of the counterweight chain in the same manner as described above for the other sheave.

The stop features do away with the automatic electric switch devices which have proved so troublesome for this type of hoist, as well as for skip hoists; and they secure an exact stop for all such hoists without involving failure from human carelessness or complicated electrical equipment. Simple push button mechanism controls the device. The battery of hoisting motors as well as the arrangement of the equipment is shown in the accompanying illustration.

# Turning the Wheels of a Century Hence—II

## Water Power—Some of the A-B-C's That Govern Its Existence and Development

By C. H. Claudy

IT is true that any flow of water is a manifestation of power and that could we utilize that power our power troubles would disappear. But there are certain natural laws and certain economic laws which prevent our doing so. To make this the plainer, consider one of the fundamental theories of water power, which is that there is a fixed relation between "head" (which means briefly, the height from which the water falls) and the quantity of water falling. To develop the same power, the greater the height the less the quantity need be—to develop the same power the less the height the greater the quantity must be. In theory then, if we had a very large river with a practically infinite flow, we could get all the power we wanted out of a one-foot fall by using a great many small wheels, each of which would be moved by the small power of so small a fall. Practically, we can do nothing of the kind, as the installation would be too tremendously expensive and the maintenance too great.

Mere flow of a river, then, does not indicate a power source which is available. To make that power available, we must have a fall of sufficient height to turn, economically, a wheel which will give out power which is not more expensive than the same installation and upkeep would procure through the use of fuel.

There are certain locations where this condition occurs naturally and many others where it can be created artificially. But by no means all natural locations are economic locations, because of the fact that they are not near enough to the market for power. One of the greatest water powers in the world is in Africa, but it is as useful to us as the ice at the North Pole is useful to the icemen: we can't make it available because we can't transport it.

Power is not a *thing*, which can be made, packed, stored and used in the future. With a few exceptions, it must be used when made and largely where it is made. Electricity, of course, can be transported (the phrase is inept, but carries out the simile) by a suitable installation of conduits—electricity brought into being and under control at a power-dam site can be made available to do work economically up to a distance of two hundred and fifty miles, sometimes a little further away.

A curious limitation to the "transportation" of electric power is found in the cost of copper. Copper is the only metal we have of sufficient strength, and sufficient ability to "conduct" electricity, to enable us to use it as a long power line. Copper is costly. The farther away the source of electricity, the greater the voltage must be to force the current through the long line. The greater the voltage the better must be the insulation if the current is not to leak away. So a very long line means a very costly installation. Moreover, the longer the line the greater the drop in potential, and there comes a point where the difference between power developed and power delivered is greater than the economy of water power over coal power. Hence the geographical location of natural sites is a limiting factor to the economic possibilities.

The schoolboy is frequently amazed at the fact that large rivers so frequently flow near big cities. His elders say truly that if the natural power-site is too far from industry, industry may move. And industry has moved, and will continue to move to points where it can get power. It seems unquestionable to many minds that the great economic development of the future lies on the western, rather than the eastern coast of this country because it is the western coast which has the greater water-power possibilities and because coal exhaustion will naturally send power users where the power is. This, of course, is predicated upon the thought that we never are to learn how to "transport" power long distances or how to "store" it.

By no means all natural falls are economic from a development standpoint. There is a limitation in nature which is of the greatest concern to water power development engineers. This limitation is concerned with the flow of the water—its maximum and its minimum. We have learned how to take care of flood water, and we know how to provide against the time of little water; but it is one thing to know how to do a thing and quite another to do it.

Let us suppose a river with a great water-fall, let us say of a hundred feet. During ten months of the year the water coming over is sufficient for the power being developed. During two months the natural flow is diminished to such an extent that artificial storage must make up the deficit. This situation the engineer meets by the creation of a storage lake of sufficient size to hold enough water to keep the power-flow constant during the slack months.

Now let us suppose another river with a fall of twenty feet. Roughly, there must be five wheels on this falls to develop the same power which one wheel develops with the greater fall. If this river is slack for two months its storage reservoir must be five times as large as that of the smaller river with the greater fall. But a lake five times that size may be utterly impossible of construction in the basin behind the falls.

To make this the plainer, consider the Great Falls of the Potomac eighteen miles north of Washington, D. C. Here is unquestionably a great water power going to waste, which could develop in times of normal flow more than enough power to light the streets and the homes of the capital city, run its plants and its elevators, turn its wheels and propel its street cars. But the Potomac comes down through a narrow gorge or rocky valley. There is no place available to make a lake of sufficient size to hold water enough to tide over such a plant at times of slack water. The variation between the normal flow and the low water is very large, and between flood water and low water enormous. A plant calculated upon normal flow would require a storage reservoir much larger than the terrain makes possible. Therefore, to make a power development at Great Falls a practical matter, a steam plant would have to be installed to take up the load when the water power failed. This expedient is very common, but of course means increased expense, a large overhead and maintenance, a coal pile constantly on hand, additional insurance, increased labor, all of which factors enter into the cost of the water power.

There is a great and fundamental difference between a factory producing power and a factory producing baby carriages or refrigerators or machine tools or locomotives or pianos. There is a fluctuating demand for manufactured commodities. In the case of refrigerators, for instance, spring and summer see a demand, fall and winter a falling off in demand. If the factory was built to the size of the spring and summer demand it would be too large in fall and winter. If built to the size of fall and winter demand it would be too small for the spring and summer demand. So it is built with a capacity between the two. In fall and winter it makes more refrigerators than it can sell, in spring and summer it makes less than it can sell. The cold weather surplus becomes the balance wheel against the warm-weather demand.

But a factory for power has a demand which fluctuates not by seasons but by hours, and has no way of storing its power production during the minimum load hours. It must, then, be built to supply its greatest demand, and always have idle units during times of lesser demand. This increases the cost in two ways: in the first place by the extra investment, which part of the time does not earn dividends; and second, by the deterioration as well as the running expense of the plant not engaged in producing power which is sold.

These expenses are less in the case of water power than steam power, for this reason: an idle water-power plant (idle during a part of the day) means no fuel expense. An idle steam-plant must still keep up steam in boilers, and while fires may be banked and some coal saved, nevertheless steam pressure and heat must be wasted if the load is to be picked up promptly when it occurs during the next peak-load hour. Again, therefore, those low heads which require steam plants as aids in time of low water, are much less economical developments of "white coal" than are the high-head streams where the water storage can be sufficient to take care of seasonal fluctuations of water supply.

All these considerations have been put forward that there may be a real understanding of the great difficulty of making any genuine estimate of the maximum possible water-power development in the United States. There are those proponents of water-power development who contend that the amount of undeveloped water power within our borders is far greater than engineers will admit. And from the standpoint of possibility they are perhaps right. But when an engineer estimates undeveloped water power he does not consider the possibilities but the economic probabilities. Such an engineer would doubtless call the Great Falls of the Potomac an undeveloped water power, but would not call "Little Falls" close to the city a water power at all. True, it *could* be made into a dam and supply power, but the head would be so small, the storage practically so little, that it wouldn't be nearly so economical as burning anthracite, let alone bituminous coal.

Remembering that distance from available market, difference between high and low water, differences in demand, amount of head and possibility of storage all limit the practical development of a flowing stream into a power station, consider some statistics which have been gathered regarding water power in this country.

The Geological Survey estimates, as of January, 1920, that there is produced in the United States an average of 1,200,000,000 kilowatt hours of electricity by water power and an average of 1,800,000,000 kilowatt hours of electricity by fuel. Of the total amount of electric power produced, therefore, about forty per cent is water power and the balance fuel power. These figures are for consumption in public utilities, and do not include power for manufacturing or in private plants for light and power otherwise used.

The available horse-power which *could* be developed by the use of water has been estimated at nearly twenty-eight million as a minimum and about fifty-four million as a maximum. Such figures are not inclusive of any possibilities of storage by huge reservoirs but merely take into account the development of existing natural power, or the construction of economical artificial powers (dams for power or navigation purposes).

But as we have seen above, it is not feasible to set a maximum limit because no one knows what the possibilities may be when demand becomes acute. The maximum figure may be less and is probably more than that indicated. In making its calculations the Survey states that in determining the minimum horse-power the minimum flow for the lowest two consecutive seven-day periods in each year was determined, and the mean of these values for the period was taken as the minimum flow. The maximum was determined on the assumption that wheels may be installed up to an amount of flow that can be assured during six months of the year. The estimates assume power measured on the turbine shaft with 75 per cent wheel efficiency.

No estimates based on the possibilities of storage have ever been made which were in any way reliable. Of this problem the Commissioner of Corporations said in a report on water power, "The difficulties of estimating the possible power development of a stream multiplies when an attempt is made to estimate the supplemental reserve force that can be put into it by storage. Not even the authors of such estimates have yet ventured to publish them in detail; they have generally confined themselves to a total for

(*Continued on page 50*)

*THE first article of this series endeavored to make plain that, outside of the fuels, the only power resource which is available with present-day knowledge and present-day methods and present-day economic conditions is that of gravity, made manifest and useful through falling water. We have not yet found an economical way of harnessing tide-power, sun-power, earth heat, atmospheric electricity, earth rotation, atomic or molecular power. We have found methods of harnessing water power. But while the water-wheel is ancient and its development great, it does not necessarily follow that wherever there is falling water there is power. Some of the reasons for this statement, with a discussion of how we may tell where we have water power and how much water power we have, constitute Mr. Claudy's theme in the present discussion. In the final number of the series he will pass to a consideration of what we have to do to make this power available.*—THE EDITOR.

# Measuring Steam

## Methods and Instruments for Determining What the Power Plant Is Doing

By A. R. Surface

IT is only within a comparatively few years that engineers have interested themselves in the metering of steam, but the attention now devoted to the efficiency of operation of industrial plants has created a demand for apparatus which will provide definite information as to the quantity of steam flowing through a pipe. The question of steam measurement first came into prominence in connection with tests of steam-engine efficiency, and the general practise was to condense the steam and to measure or weigh the resulting water. The measurement of steam—as steam—is a different matter altogether, and a far more difficult one.

The most obvious field for steam measurement is when steam is sold to an outside purchaser, or supplied to some department of a factory which has to keep separate costs. The power-plant, as the producers, are not concerned with the efficiency with which such steam may be used, but have to be paid for what they supply. On the other hand, the consumers of steam may rightly demand that they should be charged for steam only and not for water of condensation entrained with the steam. Again, in these days of large boiler plants, the engineer in charge should know how much steam each boiler, or at least each battery of boilers, produces in order to have a check upon their evaporative efficiency as affected by the kind of coal burnt, the method of firing, or the condition of the boilers. Individual water-meters on the feed lines of each boiler, even when fitted as they very rarely are, do not adequately meet the case, for they register all water entering the boilers, including much that is not turned into steam at all. Moreover, the ordinary water-meter merely counts the number of pounds or gallons which have passed, and gives no indication of the rate of flow at any time. Hence there is an increasing tendency for the provision of steam-flow meters in boilerhouses where a high efficiency of operation is aimed at.

Numerous other cases in which the direct measurement of steam is desirable or necessary will at once occur to the mind. The steam supplied to gas producers, for example, must be measured as steam or not at all, and a large number of industrial or chemical processes use steam, the amount of which must be known by the management if the best results are to be obtained either from the process or from the steam generating plant.

Most practical steam meters are based upon one or other of two principles. Either there is a slight constriction inserted on the steam pipe so as to cause a small pressure difference on the two sides, which will vary with the amount of steam passing, or the velocity of the flowing steam is measured by a sort of Pitot tube. The actual measuring instrument can be placed at any convenient distance from the steam pipe and is connected to it by means of two small copper tubes filled with water of condensation which transmits the differential pressure to the instrument. The latter may be constructed either simply to indicate on a dial or scale the rate of flow of the steam at any instant, or to record the rate of flow graphically on a diagram, or to integrate numerically by means of a counting mechanism the quantity which has passed in any given time. Indeed all these functions can be combined in one instrument if desired.

Although the average steam meter at the present time can hardly be classed with instruments of the highest precision, it must be remembered that measurements of steam in ordinary industrial practise need be no finer than is possible in the case of coal or water. If what is called "commercial accuracy" can be obtained in the metering of steam it is as much as the ordinary engineer will demand. Given fairly steady conditions of pressure and superheat, and not too great a variation in the rate of flow, several types of meter will record the quantity of steam passing with an error of about 2 per cent, which is sufficiently accurate for most practical purposes. In the steam meters of continental design which are now on the market little attempt seems to have been made to compensate for the errors which must occur if there is any considerable variation in the steam. The principal British makers, however, employ an ingenious automatic correction for this error, and their meters are in consequence highly accurate over a considerable range of pressure. The same firm issue with their meters a table by which the readings may be corrected for the density error arising from variations in superheat, but no automatic correction for this error has yet been embodied in commercial instruments. It may be taken that the best steam meters working under commercial conditions will give results correct within plus or minus 2 per cent, at loads ranging from three-quarters to full load. At half load the accuracy will be within 2½ per cent, and from one-quarter load to one-sixth load it will be within 4 per cent. Such accuracy can be obtained only by calibrating each instrument under conditions similar to those under which it will have to work.

The mechanical methods adopted to translate the difference of pressure due to the flowing steam, whether determined by a constriction in the pipe or by a Pitot tube, into the actual readings of an instrument differ widely. The simplest instruments of all, those which merely indicate the rate of flow at an instant, sometimes do so by allowing the differential pressure to act upon liquid in one limb of a U-tube, thus causing the liquid to rise in the other limb and to indicate by its height the rate of flow, which is read off a suitably graduated scale placed alongside the liquid column. Water is sometimes used as the indicating liquid partly on account of the ease with which it is automatically supplied by condensation, and partly because of the open scale obtained with very small pressures. Mercury, however, is frequently adopted. For equal pressure-differences the height of the mercury column is only about one-thirteenth that of a water column, s

### Science in Painless Doses

To the Editor of the SCIENTIFIC AMERICAN:

The recent communication from New Mexico containing some truly remarkable revelations concerning the solar system reminds me of a short article I read in the Sunday magazine section of one of the Pittsburgh papers some three months ago. This article, which unfortunately I did not preserve, was written as an authoritative explanation of some of the everyday scientific phenomena which we meet. Among other things it discussed the starting and stopping of a heavy train. It pointed out very nicely how both these operations require investment of energy, the one to negative the momentum of the moving train and the other to create such momentum. Of course, it said energy when it meant momentum, but we can pass that by to get at the main point. Having got this far, the author proceeded to explain, at some length, that it takes more energy to stop the train than it does to start it, because the amount of energy which it has by virtue of its motion after it gets going is greater than the amount of energy which it does not possess when standing still.

### About That "Power Famine"

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of April 17 is featured an article entitled "California's Power Famine." This has come to the notice of a large number of our membership, including the Committee on Manufacturing of the Chamber, who feel that this startling headline is very damaging and not in accordance with facts.

It is true that there is a water power shortage in the state. This is most severe in the north, less severe in the central part, while in the southern part of the state plenty of power for all purposes exists through the foresight of the city of Los Angeles in constructing its 250-mile aqueduct some eight years ago, the hydroelectric power house on this aqueduct and the completion next month of an additional power house.

The article in the SCIENTIFIC AMERICAN is of a tenor to halt all enterprise in this section dependent upon electric power. Unless there is enforced pooling of all power in the state, the southern part of which Los Angeles is the metropolis will be well able to meet all demands and make good our claim that we have plenty of power at reasonable rates.

Could you not put these facts before your readers in order that they may be familiar with the situation as it is?

LOS ANGELES CHAMBER OF COMMERCE.

### Cinder Concrete

To the Editor of the SCIENTIFIC AMERICAN:

On April 10th you published an article entitled "Carbon Concrete." I suggest that any move to use cinders in re-enforced concrete is very dangerous. I saw not a few floor slabs after the San Francisco fire where the steel in contact with the cinder concrete had almost entirely oxidized. I myself removed a large outside porch floor made of cinder concrete re-enforced with a heavy expanded mesh, the spans being about eight feet between I-beams and the expanded metal and the top of the I-beams as well was almost entirely eaten away; and it is a wonder there had not been serious accidents.

I also removed a re-enforced concrete wall where the sand used had been sweepings containing a small portion of hard wall plaster or sulfate of lime; the ¾-inch twisted rods had entirely oxidized in less than four years.

No aggregate should be used in re-enforced concrete where there is even a suspicion of sulfur or sugar.

As a matter of interest, in 1907 I rebuilt an old warehouse. The twisted steel rods in the foundation located at about high tide level had been in the wall twenty years. They were in perfect condition, with not even a speck of rust upon them, although they had been alternately wet and dry daily for twenty years. Originally twisted but once in twenty diameters, I retisted the rods to once in ten diameters, had them tested and re-used in new work. But keep cinders away from concrete where steel is used.

Los Angeles. CHAS. E. RICHARDSON.

### Maternal Impressions

To the Editor of the SCIENTIFIC AMERICAN:

In reference to your science note on "Maternal Impressions in Canaries:" A friend of mine has told me of a man he knows who lives near a railroad at a spot where the engines always whistle. He told my friend that he had never been able to raise chickens there as they were always deformed when hatched and died shortly afterward. This man wanted my friend to hatch some eggs for him and told him of the circumstances and if it were not that I had told my friend about the canaries he would have told him he didn't know what he was talking about.

I have suggested an experiment which would be interesting and that is to exchange eggs and hatch them. They would then know whether the damage was done when the egg was forming or when it was being hatched.

Maybe you could tell me whether this has already been tried.

LEONARD W. SMITH.

Newark, N. J.

[*We do not know of any such experiment that has ever been carried out. Perhaps some reader does, or will be provoked by Mr. Smith's letter into trying it.*—THE EDITOR.]

### Not Yet Time to Scrap the Switch Engine

To the Editor of the SCIENTIFIC AMERICAN:

In connection with your recent article, "Getting Along Without the Switching Locomotive," I would make a suggestion. All indications are that sooner or later the railroads will be electrified, and when that development has reasonably progressed it will be time to do away with a principle so strongly adhered to in railroading. The horse pulls the wagon, let the locomotive pull the cars.

The ultimate result of the electrified railroad must be that the cars pull themselves, headed by a small auxiliary locomotive or the baggage car. The economies inherent in this principle, both in maintaining the roadbed and in eliminating the big locomotive should speedily help to pay the cost of the electrification of the railroad.

# Toys That Do Great Work

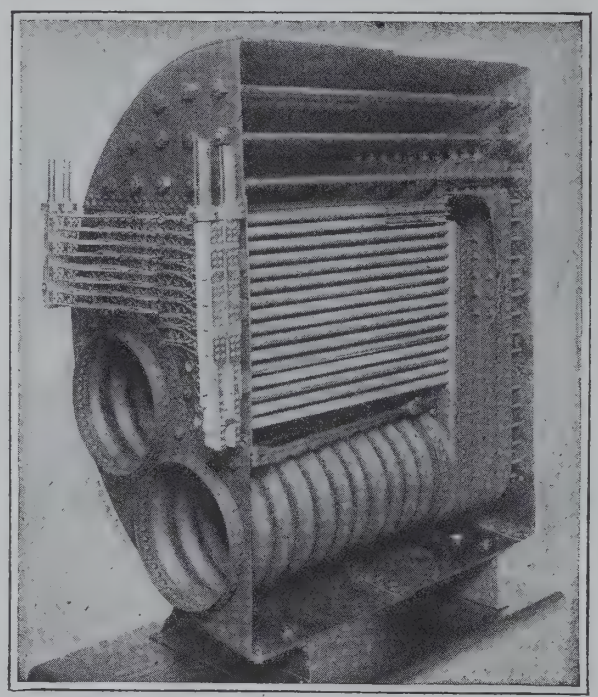
## The Indispensable Place Occupied by Models in the Engineering of Today

By M. A. Henry

A MODEL engine, or a model steamship or skyscraper is not always a toy or merely a thing of sentimental value. We too often think of a model as the work of a "tinkerer" and are apt to forget that model making has its definite place in modern industry and that the model maker is a highly skilled workman who works with great precision.

Recently at an important murder trial a model of the scene of the tragedy was introduced to show more clearly to the jury "just how it happened." The model had been made by a "tinkerer." It was shown to be inaccurate and was ruled out as evidence. The professional model maker knows that one of the most important uses for models is in lawsuits and he knows that this may prove a most exacting test for the accuracy of his work.

During the war an engineering firm undertook the erection of a large drydock for the Navy at Seattle, Wash. It was found that because of conditions which could not have been foreseen, a great deal more construction work than had been thought necessary was required. Suit was finally brought against the Navy for the extra expense incurred. The case was a very complicated one and difficult to present to a jury of non-technical men. The attorney for the company admitted he had failed to "put across" his point and then a happy thought occurred. He called in Horace E. Boucher, a famous model maker of New York, a model was constructed to exact scale and the jury could then be readily shown the point at issue. The model served its purpose so well that it "saved the day."



Model of a boiler, showing tubes and all other features

For the trial of another suit, involving the patent rights for a well known make of steam turbine, more than $3,000 worth of models were constructed and used as evidence.

In the trial of the German, Fay, who was caught attaching bombs to the stern of vessels, a model was again used to advantage. The bomb Fay used was attached so that it was actuated by the ship's rudder in much the same manner as the balance wheel of a watch regulates its movement. Fay had calculated the number of turns the ship would make so that the bomb would explode after the ship was well at sea. The whole conception was so fantastic that to convince the jury a six-foot model of a ship's stern was made and a small working model of Fay's bomb (minus the explosives) was attached. Fay was convicted.

There are almost countless other instances where models have played important parts in lawsuits, but this is not their only practical use. They are very essential in the shipbuilding industry. For every steel ship built a "plating model" is made. This is a wooden form of half of the ship's hull. On this the steel plates of which the real hull will be made are laid out and the plates are ordered from this model. This is necessary because of the irregular shape of the hull, making an accurate blue-print impossible. Another model of the hull is made and towed in a testing tank and its resistance to motion in the water

### Bill Boards That Travel Through the Streets

SAN FRANCISCO has a new and quite unique way of combining business with pleasure. The "Baseball Special," a string of trolley cars running to the ball grounds, carries a huge poster which advertises the date and time of each game. Only one side of the car carries the bill board, the other side being left free for light and air.

### A Machine That Is Rougher than the Freight Handlers

IN a test for strength of shipping boxes, the object of which is a simulation of the rough knocks, bumps, and jars of handling which a loaded box may encounter in railroad traffic, there has been designed a machine by which the railroad usage which a box may meet in a 2,000-mile haul can be duplicated in four or five minutes.

The first machine of this kind, known as the drum box-testing machine, was designed by the United States Government Forest Products Laboratory at Madison, Wis. The Mellon Institute of Industrial Research of Pittsburgh, Pa., has recently installed a machine which is said to be an improvement over the original tester in that the inconvenience of overhead pulleys and shafting has been done away with by the substitution of a reduction gear for cutting down the motor speed to the drum speed of two revolutions per minute.

A valuable field of investigation and scientific study of construction and materials of packages is opened up by the new machine, such as best methods of interior and exterior packing for fragile or irregularly shaped objects; the determination of proper specifications for containers carrying various commodities, etc. An offer of free service in the designing of scientific packing methods for the various commodities capable of being shipped in fiber containers, which includes the use of this equipment, is being advertised by the Container Club of Chicago, an association composed of corrugated and solid fiber box manufacturers of the United States.

### A New Use for the Old Diving Bell

ALWAYS seeking new fields of exploitation, the motion picture producer is not one who hesitates to plunge into something new in the way of submarine devices. Indeed, the Williamson submarine tube, which for years had little if any real promise of practical application, suddenly came into its own as a means for producing marvelous underwater scenes for the motion picture screen. And now a Western inventor, A. B. Barringer, has worked out a modified form of diving bell shown in the accompanying illustration, for the purpose of taking submarine pictures.

The Barringer equipment is the usual diving bell construction, but instead of being open at the bottom, it is closed. A heavy plate-glass window is provided in one side of the steel shell in order to operate a motion picture camera or the usual "still" photograph equipment. Air is furnished to the operator by means of a conventional air pump. Weights are mounted about the casing in order to secure the desired results. So far, tests of this equipment have been highly successful, and the screen may soon be favored with a fresh lot of submarine pictures which are always fascinating to us creatures who live in a different element.

### The Largest Motor Boat Afloat

IF you let your eye range down the full 445 feet of deck length of the fine freighter shown in our photograph you will notice at once, if you are familiar with ships, that she has no smokestack—and this of course proclaims her to be a Diesel-engined vessel. The "Africa" has recently been built in Copenhagen for a London company. She is 445 feet in length, has a beam of 60 feet, and her carrying capacity is 14,000 tons. She is driven by Diesel engines of 4,500 horsepower, and on the strength of her power and size she is credited with being the largest motor boat in the world.

This vessel and other large Diesel-engined ships which have recently been built or are now upon the ways, show that the internal combustion engine is steadily, if rather slowly, making headway as a successful drive for ships of the largest size. This advance would be more rapid were it not for the limitations of size of individual cylinder dimensions imposed by internal combustion conditions. In the present state of the art there is a point at which cylinder capacity for the single cylinder is restricted, and this being so, it becomes necessary to resort to a great multiplication of cylinders in order to reach a large total power output on the propeller shafts. The Germans, at least up to the close of the war, seemed to have advanced further than other engineers in this direction. If a satisfactory gas turbine should ever be developed, the question would be solved for ships of the largest power. The advantages in fuel economy, increased cargo space, reduction of engine and boiler room force, to say nothing of the speed and convenience of fueling, are motives which are urging marine engineers to bend every effort to the solution of this problem.

### Other Metals with Radioactive Properties

IN addition to the ordinary radioactive substances, which are all closely related to uranium and thorium, two elements of the lightest atomic weights known, only two of the light metals of relatively small atomic weights, potassium and rubidium, seem to be radioactive to a certain extent. The nature of this latter radioactivity is by no means understood, while a great deal is known as to the character of the ordinary radioactivity. In case of the radium and the other radioactive elements there is certainly a decay of atoms. As regards potassium and rubidium we have no definite evidence of any decay. In discussing these problems in the *Physikalische Zeitschrift* some time ago, Otto Hahn and the late Martin Rothenbach point out that, while several investigators are convinced that these alkali metals emit beta rays, alpha rays have not been discovered; it is on the other hand striking that the potassium salt deposits of Stassfurt are rich in helium. The radioactivity of the alkali metals might be due to some impurity; but no impurity has been traced, and the radioactiviey observed is always proportional to the potassium percentage, *e. g.*, the intensity of the radiation from potassium which was first observed by N. Campbell at Cambridge in 1906, is very small; yet it was considered to be at least 10 times stronger than that from rubidium. Hahn and Rothenbach made their experiments especially on the sulfates of potassium, rubidium and caesium, with the aid of electroscopes of unusually large dimensions. The following are the conclusions at which they arrived: There is no indication of the presence in rubidium of some isotope; the beta rays from rubidium seem in penetrating power to stand between uranium X and radium proper; the ratio of the activities in rubidium to uranium as 1:15, and rubidium to thorium as 1:10; the life period of potassium would probably be from three to seven times longer than that of rubidium. Speculations have been made by others as to a possible production of strontium from rubidium, calcium from potassium, and barium from caesium; but such speculations appear to be quite arbitrary for the present.

**Two of the clever dodges whereby the automatic telephone is enabled, pending its complete installation throughout the city, to work with the manual offices**

# The Mechanical Hello Girl

## An Automatic Telephone Switchboard That Can Take Care of the Busiest Exchange

By H. A. Mount

THE automatic telephone is not new. Efforts to build a telephone system in which any subscriber could be automatically connected with any other desired subscriber without the aid of a human hand, began in 1879, only three years after Dr. Bell produced the telephone.

But an automatic telephone exchange in a big city, such as New York, where there are in the neighborhood of a million telephone stations served by 100 central offices is decidedly new and of great significance. In the years between 1879 and the present many inventors have tackled the problem and there have been many systems of automatic telephony invented. Automatic telephones have been used successfully in towns and smaller cities for several years but their introduction into the big centers of population like Chicago, Philadelphia or Boston presented obstacles which seemed well nigh insurmountable.

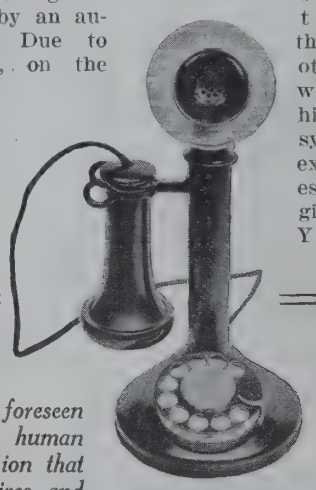
Where a community is served with a single central office or two or three central offices the engineering problem was comparatively simple. A system had to be devised which merely made it possible for any subscriber in the system to reach any other subscriber.

But in New York not only must each of the 1,000,000 subscribers be able to reach any other, but due to the large area involved, many of the calls involve extra charges, which means that they must be supervised, timed and ticketed. Then there are the following general classes of service demanded by the public: Flat rate limited, message rate, official, coin box unlimited, and pay station. Add to this single party, two party and four party service and picture a densely populated surrounding country with several hundred towns and cities from which come and to which go thousands of messages each day, all of which have to be supervised, timed and recorded.

That an automatic telephone system capable of doing all these things and many others could be devised seems little short of marvelous. And yet the biggest problem of all was not in doing these things, but in devising a system which would operate in harmony with the existing manual central offices.

It will be seen that the task involved in changing to automatic telephones in a large city is stupendous and it would be a physical impossibility to convert the whole system at one time. The change must take place gradually, one central office at a time changing to automatic switching, until the whole job is accomplished. The change must be made without interruption of service and for a period of some years the new automatic apparatus must work in harmony with manual apparatus.

The first part of New York's automatic system is now in operation and the whole city is to be converted to automatic switching as fast as apparatus can be manufactured and installed. The process will be so slow, however, that telephone officials say they will not have to discharge a single operator replaced by an automatic switchboard. Due to the normal labor turnover, on the other hand, the company will have continually to hire more operators. The system is constantly being extended, too, and it is the estimate of telephone engineers that in 1950 New York will have at least 2,700,000 stations served by 225 offices.



*THE telephone system has attained a complexity which its inventor could hardly have foreseen when he was struggling to reproduce the human voice at the other end of a wire. The suggestion that all the business of this vast network of wires and switches might be performed automatically seems at first blush preposterous. But every day it is harder to recruit the army of operators needed for the manual exchanges. It becomes ever more necessary to devise, not a means of doing away with the operator, but merely of getting along with the operators that can be obtained. Largely on this account a determined effort has been made to apply automatic telephony to the large and busy exchange as well as to the small and comparatively idle ones; and incredible as it may seem, this has been a complete success. We may look forward with certainty to the day when any two instruments in New York City may be connected without the intermediate agency of any human operator. This is the story which Mr. Mount presents to us here.*—THE EDITOR.

The first makers of automatic telephones had a single exchange to deal with and only a few subscribers. The first machine switches produced had a separate switch for each line, so arranged that it could find and connect directly with any other line in the exchange. The long adherence to this plan was probably one of the principal causes for failure of these early systems. The first systems to succeed to any marked extent made use of a scheme of trunking whereby the calling line was extended link by link until it reached the called line on a very much smaller multiple group than the total number of lines in the exchange.

The first system to find any commercial application makes use of this fundamental trunking principle. The switches are the "up and around" type with 10 vertical and 10 rotary steps, each switch accommodating 100 lines or 100 trunks. A dial with the 10 digits 1 to 0 is provided at each subscriber's station. The subscriber in calling manipulates this dial. This sends impulses to the switches, which cause them to build up the connection desired.

For example, when a subscriber calls a four digit number, as 9653 in a 10,000-line system, the first movement of the dial by the calling subscriber will send nine impulses to the central office corresponding to the thousandths digit, and the switch under direct control of these impulses will step up nine times and extend the line to another switch which serves the ninth thousand. The next movement of the dial will send six impulses and this will cause the switch of the ninth thousand to step up six times and extend the line to a switch which is capable of reaching the hundred lines of the sixth hundred of the ninth thousand. The next movement of the dial will send five impulses to correspond to the tens digit and will cause this last switch to step up five times. The last movement of the dial will send three impulses which will cause this same switch to take three rotary steps and thereby complete the connection. Of course the system is more complicated than this because there is machinery for automatic ringing, for giving busy signals, and the like. But most of the automatic systems in use follow these general lines. There have been many minor improvements in this system but the general principle has not been altered.

More recently there has been devised the "automanual" system, which as its name implies, includes some of the features of both the automatic and manual systems. In this system the subscriber calls central and gives his number in the usual fashion. But Central sets up the number on a switchboard with very much the appearance of an adding machine and the switching is done automatically.

There were several reasons why these systems, although used successfully in many places, could not be adapted to the needs of large cities. It was found that too great a mass of machinery and equipment would be needed and to meet this objection a new type of switch

had to be devised. The basic necessity of having a large number of trunks in one group added another difficulty—the system could not be laid out on a 10 x 10 or decimal basis. At the same time it was obviously desirable that the calling device be operated by the subscriber on a decimal basis. With a large number of trunks in one group, it was found that there was not sufficient time between one set of impulses and the next to permit the switches to hunt and find an idle path or trunk.

To meet these and other objections the "sender" was devised and it is declared to be the greatest single advance in the art since the selector switch. Instead of controlling the switches directly by the impulses from the subscriber's dial, these impulses are received and literally stored up by the sender. The sender then allows the switches to go upward to the desired point and then stops them by removing their driving power. This permits the usual decimal system of numbering, but the sender can be arranged to translate these decimal impulses to any desired non-decimal system, permitting the most advantageous arrangement of wiring and switches to meet any given condition. It permits the elevators or switches to hunt over any number of trunks in a group without any reference to the speed of the calling device. This fact permits the building of rugged power-driven switches which can be operated at their best speed on circuits local to the central office. It solves the most serious problems of the large cities by permitting the most economical arrangement of trunks outgoing from any office; it allows trunk groups to be made larger or smaller and permits shifting the multiple from one place to another to meet changing conditions. Thus, the sender makes the system flexible and less costly and the most economical layout can be used without fear that future expansion in any direction will be blocked.

It must be remembered, however, that the transition period in a large city extends over a number of years and during at least half of this time most of the calls would originate in manual offices. One of the chief problems to be met was finding a satisfactory method of sending calls from manual offices to mechanical offices and from mechanical to manual offices.

Three successful methods of handling service from manual to mechanical offices have been worked out, each best suited to a certain condition. In the simplest of these, the manual operator is provided with a dial similar to the subscriber's dial and when she receives a call for a mechanical station she dials it for the subscriber, having first "plugged in" on an idle trunk line.

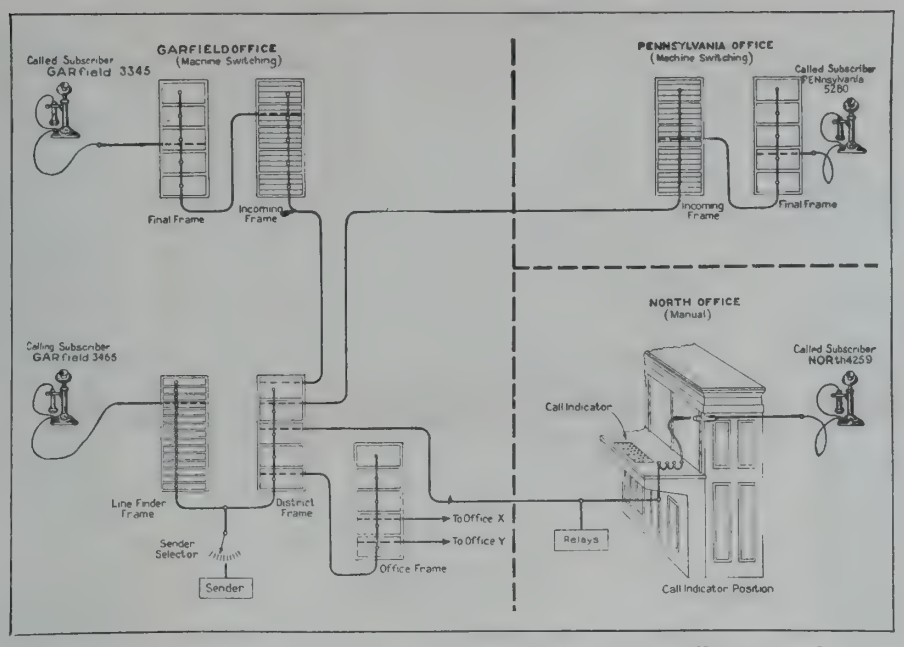


**Diagram showing progress of a call from an automatic subscriber to another automatic instrument or to a manual-station subscriber**

The advantage of this system is its low first cost but it has the disadvantage that where the number of calls is large it slows down the operator. It will be used only in small cities where traffic is light.

Another is called the "key indicator" plan, and permits the manual operator to complete a call to a mechanical office very speedily without the aid of any other operator. When the subscriber gives the number desired, if it is in a mechanical office, the operator depresses a key corresponding to that office and an idle trunk line is automatically selected for her and indicated by the flashing of a small lamp. She "plugs in" on this line, having depressed the digits of the desired subscriber's number on a 10-button "numerical key" with which she is provided. A "sender" which has been attached automatically proceeds to guide the connections in the distant mechanical office. This plan is to be used in offices where it is proposed to retain the manual equipment for a number of years, as it involves a large cost and extensive changes of equipment in the manual office.

The third plan and the one to be quite frequently used is the scheme of using "cordless B" operators in the mechanical offices. The plan contemplates that the call will come in to the manual switchboard in the usual way and that the operator will handle the call as though it were to another manual office. At the incoming end, the "cordless B" operator will receive the number and will set up the number on the keys before her. A "sender" is provided to receive and register this number and to cause the desired line to be found and rung. This plan has the advantage that no changes are necessary in the manual office.

Calls from a mechanical to a manual office are always handled in the same manner. The manual operator has before her a "call indicator" consisting of a table of figures, any one of which can be illuminated by lights beneath them. The incoming call is indicated in the usual manner but instead of having the subscriber repeat the number wanted, it is set up on the "call indicator" by the illuminating of the proper figures. Thus so far as the full mechanical subscriber is concerned a call through a manual office appears to him the same as a call to another subscriber in his office. The operator then puts through the call in the usual manner.

In fact, the progress of a call through a full mechanical system is parallel in a striking way to that of a call through the manual system with which we are familiar and it may make the function of the apparatus more clear if we consider the similarity. When a subscriber in a manual system removes his receiver to make a call, he causes the line relay at the central office to pull up and light a lamp associated with an answering jack. An operator takes up the answering plug of a cord pair, plugs in and answers. In a full mechanical system the subscriber removes his receiver, causing his line relay to pull up but instead of lighting a line lamp, it applies current to a row of contacts on the "line finder banks" and starts an elevator called a "line finder" going upward in search of this row of contacts. When the line finder reaches his contacts it is caused to stop by having its driving power removed.

Thus there is a marked similarity between the answering jack and the line finder contacts of the line finder bank; between the line finder and the answering cord; and between the operator finding and plugging in to an answering jack and the line finder finding and attaching itself to the contacts on the bank. After this, in the manual system, the operator, after plugging in, throws a listening key and she notifies the subscriber she is ready to receive his order by saying "number, please." In the mechanical system the "line finder" has associated with it a "sender selector" which proceeds to find and attach an idle "sender" during the period that it is finding the calling subscriber's line. The "sender" notifies the calling sub-

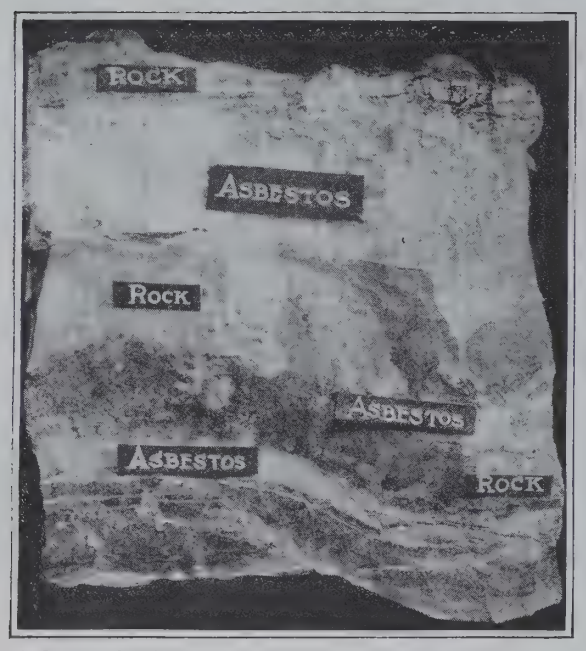
# The Rôle of Asbestos

## Some Facts Bearing on the Growing Importance of This Substance in Industry and Architecture

By Ralph Howard



**Asbestos in the natural state, showing characteristic layer formation**

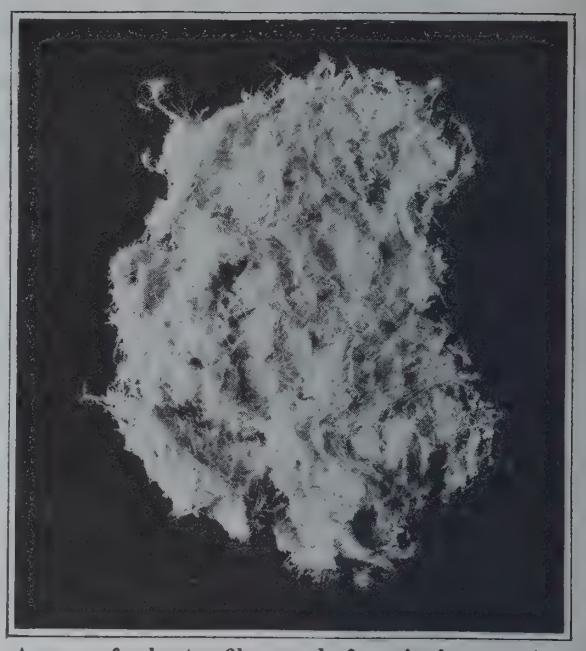
FOR centuries asbestos was but a curiosity—a mystic mineral paradox, to all appearances a solid rock yet composed of silk-like fibers so rugged in themselves that the millions of years of the earth's cooling, hardening and cracking did not break these slender threads. The ancients knew something of asbestos and held it in great awe because of the weird superstitions about its origin and powers that had been built up around it. Our early scientists knew of the properties of asbestos but it was not until something over half a century ago that the first experiments were made for using it on a commercial scale. From then on its uses grew in leaps and bounds until today it is a recognized commercial, industrial, and domestic necessity. Developed by the vision and efforts of a few great business institutions, this curio of the ancients now contributes to the world's progress and makes life safer and more complete in an almost infinite number of ways.

To look at a bunch of asbestos fiber one would think it would blaze up at the touch of a lighted match or dissolve when brought into contact with acids—yet it resists high temperatures and practically all commercial acids, the wear and tear of friction and the elements. It looks delicate, yet it can be spun into very strong yarns. While the rock itself is heavy yet these yarns can be woven into cloth weighing less than 16 ounces to the square yard, or thread weighing about one ounce to the hundred yards. The length of the fibers themselves ranges from a fraction of an inch to 4½ inches.

The almost inestimable economic value of asbestos proceeds from the fact that it possesses such an unparalleled combination of heat- and wear-resisting qualities. It is practically indestructible and resists decay and destruction under almost every condition of heat and moisture. It withstands high temperatures and has a low heat conductivity. It is a non-conductor of electricity, has a high coefficient of friction, considerable tensile strength, flexibility and elasticity. It is unchanged by flame or temperatures up to 1,500 degrees Fahrenheit, defies erosion, and is immune to climatic or atmospheric conditions.

One of the most important results of the development of asbestos has been the saving of heat through insulation—insulations that retard the escape of heat from boilers, furnaces, pipes and flues. The perfection of the heat (and cold) insulations and their application to thousands of America's power plants, is saving power and saving fuel—millions of dollars' worth annually and with the increasing cost of coal this economy is correspondingly greater.

The commercial forms of asbestos insulating materials are quite varied but the most familiar types are the sectional pipe insulations, blocks and cements used in the conservation of heat on superheat, high-pressure, low-pressure, hot water heating and circulating lines, inside and outside, overhead and underground. Asbestos insulations are highly efficient, in fact, are capable of maintaining a difference between steam inside the pipe and air outside of some five hundred odd degrees. This is a praiseworthy service not only in its mechanical ingenuity but in the conservation of every unit of heat energy necessary to maintain production at its maximum and also conserves our natural fuel resources which statistics tell us are being dissipated at an accelerated rate.



**A mass of asbestos fiber ready for spinning, matting and molding**

In addition to the saving of heat units in boilers, pipe lines, etc., asbestos is indispensable in the factory and power plant in the form of packing for air-brake cylinders and for all kinds of rods, pistons, plungers, and flanges against steam, water, air, brine, ammonia, oil, gasoline, acids and alkalies. It is invaluable as conveyer belting for handling hot slag, cinders and other materials requiring a fireproof fabric. It finds employment in helmets, aprons, coats, leggings, shoes, etc., for the protection of workmen, especially in foundries, steel mills, and glass works, where molten metals and glass are a constant source of danger to life. It is also made in the form of cords, twines, rope, yarns, paper, roll board and mill board for conditions where metal or organic materials would be quickly destroyed by the attacks of heat or acids. As a tape made as thin as 0.025 inch and as braided tubing it is used as a protective fireproof covering for conductor wires, cables, armature windings, field coils, etc., to prevent the spread of flame in case of short circuit, particularly on heavy service apparatus such as rolling mill, traction and crane motors, lifting magnets and other machinery which are in constant danger of being burned out. Also it is extensively used in compound with mica and more brittle non-conducting materials to which it gives body and elasticity. In the chemical industry it has made some electrolytic processes a success where they had previously been badly handicapped or utterly impossible. It is the logical material for filtering acids and alkalies because of its immunity to their action and the fact that it is an absolute neutral substance and does not change or

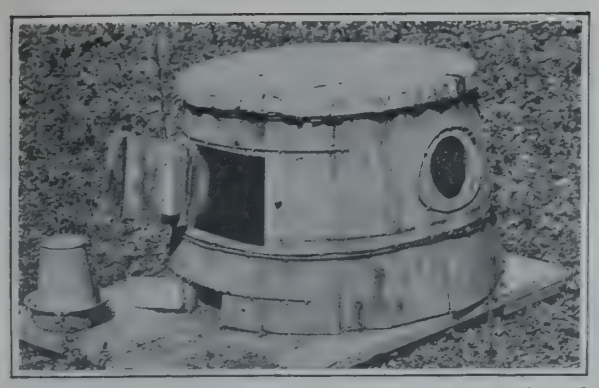
**A very sketchy exhibit of the diverse rôles played by asbestos in modern affairs**



**Considerable ingenuity is shown in the construction of this chicken coop from half of an ordinary barrel**

### A Chicken Coop from a Barrel

INGENUITY on the farm is typified by the chicken coop shown in the illustration herewith. This coop is made from half of an old barrel, with appropriate trimmings. The top is covered with heavy burlap, neatly nailed, and with the nails prevented from tearing through by metal caps, as shown in the photograph. The barrel is handsomely reinforced with heavy wire—a necessity in view of the fact that the other end with its usual binding hoops is absent, leaving the staves without adequate support. With an opening cut for the mother hen to survey the neighborhood through, and a smaller one beneath it for the chicks as they pass in and out, in addition to the ventilation ports covered with netting, it will be seen that the biddy is fixed up in great shape when she establishes her headquarters in this cleverly got-up coop. Stability is added by a wooden platform, and hooks to tie the superstructure firmly down upon this.

### What the All-Metal Airplane Can Do

THE war being over, the German aeronautical designers and constructors have turned their attention to the problems of commercial flying. And in this respect they have a decided advantage over their rivals in other countries. During the latter part of the war the Germans evolved an all-metal airplane which did excellent work at the front; and this very same construction is now outrivaling anything that can possibly be done with the wood-and-canvas construction which at present distinguishes the operations of British, French, Italian and American builders.

On June 27th last, the Larsen all-metal monoplane made a non-stop flight from Omaha, Neb., to a point 20 miles east of Lancaster, Pa. Had it not been for the dense haze which interfered with the navigation of the monoplane, it is said that the flight would have been continued to Central Park, L. I., some 25 miles east of New York City. As it is, this flight broke all non-stop records for the United States.

However, this flight is only a means of focusing public attention on the merits of the all-metal monoplane. There are still a few surprises in store for the public—aeronautic experts have already expressed themselves as regards this new construction, and they will certainly be disappointed if it does not accomplish some remarkable feats in the very near future. At the recent Aeronautic Congress held at Atlantic City, the same plane, J. L. 6, flew from Atlantic City Airport to Philadelphia and return, a distance of about 130 miles in the record time of 59 minutes and 34 seconds. It carried a total of six persons along with 80 gallons of fuel. A 185-horse-power motor was used in this flight. In the efficiency tests over the same course a J. L. 6 monoplane equipped with a Mercedes 160-horse-power motor carried eight passengers. The distance was covered in one hour and 28 minutes, and the fuel consumption was 12½ gallons for the round trip. On a trip from Atlantic City to Central Park, Long Island, the J. L. 6 carried five passengers and 143 pounds of luggage, a total weight of 1,082 pounds, horse-power used. The distance covered was about 110 miles, and in spite of the fact that the plane with its heavy load climbed to a height of 20,600 feet, it completed the trip in 80 minutes. When the all-metal plane was first reported, it was met with considerable skepticism, and naturally so; but it has easily established its position as one of the headliners of modern aero practise.

The all-metal monoplane has been introduced in this country by Mr. John M. Larsen, who has made an extensive study of aviation in the leading European countries. The machine is largely the design of Mr. Larsen, but the thick wing and metal construction features are due to Dr. Hugo Junker, whose name meant so much in German aviation during the war. In fact, this machine is a peacetime version of the famous Junker all-metal fighting plane.

It is claimed by Mr. Larsen that his monoplane will carry six to eight persons at an average speed of 112 miles per hour with only a 160-horse-power motor, throttled some; and with a six-cylinder 185-horse-power motor (no surcharging) this machine has actually taken eight persons over 22,000 feet high—a world's altitude record for an airplane carrying eight people. This and other similar performances, it is held, amount to more than double the efficiency the average plane of today is showing.

By way of comparison in the matter of size, we present an excellent view of the huge monoplane flying boat, developed for the German navy early in 1918. This machine is also of all-metal construction. The wings, as in the Larsen machine, are covered with corrugated aluminum composition. Four Maybach six-cylinder engines deliver their power to a pair of propellers and a pair of tractors. The speed is about 90 miles per hour, and the machine is capable of carrying a load of several tons.

**Huge monoplane flying boat of all-metal construction, developed for the German navy in 1918**

### Color of Brick

NOT only the ingredients in clay but the temperature at which it is burned has an influence upon the color of brick. An increase in iron is usually shown by an increase in the redness of clay. At a red heat a salmon color is obtained which becomes a deeper red as the temperature attains 1800° or 1900°F. Above this heat purple tones appear, followed by a chocolate brown and ultimately black. Buff shades are due to lime and alumina. Excess air in the kiln tends to produce a red color, while a smoky atmosphere may usually be depended upon to give a brown or black.

**This little dwelling has been constructed out of packing boxes of all sizes and shapes**

### When Packing Boxes Solve the Housing Problem

WE will not take up the reader's time by telling him about the housing shortage. That fact is pretty generally known. It is a universal problem.

A New York postman recently found himself confronted with the steadily shrinking dollar and the over-ambitious landlord. Unable to make both ends meet, he decided to build his own house on a small plot of ground near the city line. In order to get away from the high cost of building materials, this postman went to work and bought all the packing boxes he could lay his hands on. Furniture crates, piano boxes, canned-goods boxes, dry goods cases—all manner of odd sized and shaped boxes were sent out to his little plot. These he converted into a small dwelling during his spare moments, as shown in the accompanying illustration.

### Things That Go with the Car

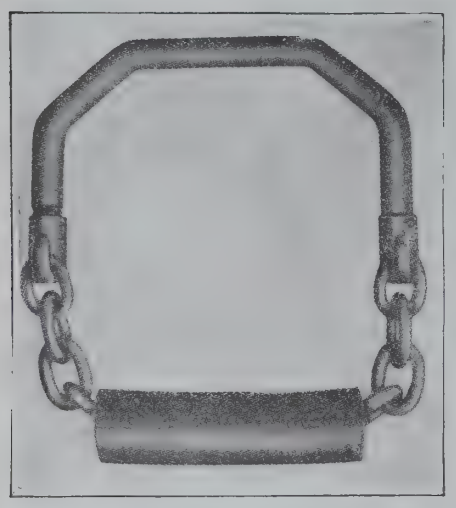
EVERY imaginable item of equipment is furnished on some of the new models for 1920, including shock absorbers front and rear, motometer, cowl ventilator, transmission theft-lock, muffler cut-out, emergency gasoline valve, located on the heel board of the rear seat and giving 1½ gallons additional supply, rubber foot-pedal pads, tire pump on the transmission, Yale locked double tire carrier, and many lesser items. Great care is being taken in the attachment of spare wheel and tire carriers, these being of exceptionally substantial construction and made an integral part of the chassis instead of being an afterthought, both in construction and appearance, as in the past.

Luxurious closed cars, especially the sedan and coupe, were again the headliners of the New York Automobile show, and the interest that is being evidenced in them more than justifies the manufacturer in increasing his production of these owner-driven all-season models during the present season. Aluminum bodies, custom designed, effect a material saving in car weight and add much to car performance and operating economy. The overall height of some of the sedan and the coupe models is uncommonly low, due to the adoption of the new method of body mounting, and the body lines are straight and unbroken, with graceful curves to relieve even the slightest suggestion of severity. A high, narrow radiator, duplex headlamps of distinctive design, a tapering bonnet of many louvres, a patent leather visor over the windshield, individual front fenders, and wide, sharp-cornered doors are some of the many salient style features of the 1920 sedan and coupe models.

These closed models have many interior appointments in common. These conveniences include a clock on the dash, roll curtains of silk, automatically-locking mechanical lifts for window adjustment, exhaust heater, large octagonal dome light, and door pockets of silk covered with large flaps. In some of the sedans, the auxiliary chairs, facing forward, are dropped out of sight in the back of the front seat when not in use, and corner lights are provided for additional illumination of the rear compartment. A walnut vanity case and smoking set are also included in the equipment items.

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*



**A non-skid grip that is easy to apply**

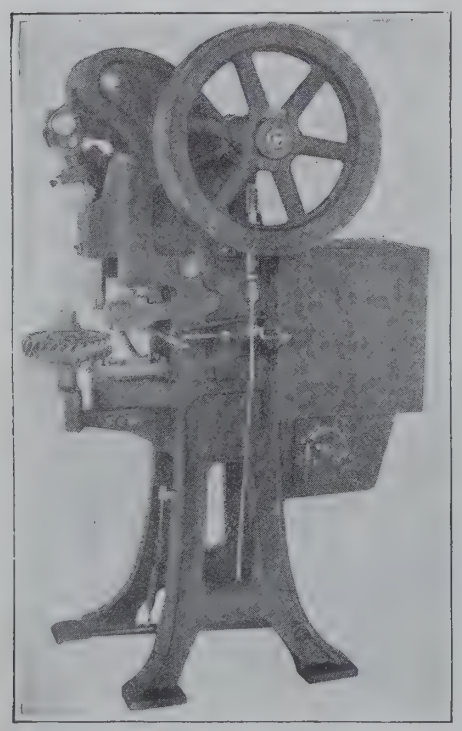
### Non-Skid Grip for Single Tires

A SET of four of these new grips for each rear tire will save the motorist many weary maneuvers in applying a non-skid device to the wheels of his automobile. This grip has obvious advantages over the continuous chain type of non-skid devices and still retains all of the road-gripping qualities the chain possesses. Made so that it fits around the wheel rim and rubber tire very snugly there is no need of adjusting in applying them. A rubber buffer of substantial thickness slips over the chain to keep it from marring up the wood spokes. The part of the device placed next to the tire is made of drop-forged steel. One end of the steel rod is fitted with screw threads and the chain portion is unscrewed when being fitted to the wheel and in operating position is screwed on tightly.—By *Allen P. Child.*

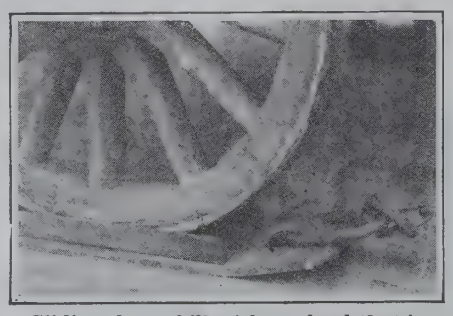
### A New Electric Riveter

AN electric machine designed for welding differential gears has been recently developed by an Ohio manufacturer of electrical machinery. The worm wheel on which the rivets are to be set is supported by a bracket at the front of the machine. This part of the machine consists of a bronze rim in which the teeth are generated, and two cast iron flanges fitting into counterbored recesses on each side of the bronze rim. The worm wheel is carried on a bracket which locates the work in such positions that by simple turns of the wheel successive rivets will be brought into position for heading. Time is saved as this method eliminates adjustments of the work for each heading.

The upper electrode is drawn over toward the operator, in operation, and just above the rivet to be heated by a lever in the operator's right hand. Another lever at the top of the machine is pulled down by the left hand and the electrode is brought into contact with the rivet. The electric circuit is completed and a push button located in the end of the left hand lever is depressed. This brings remote switch into action and current flows through the work and heats the rivet. After the proper temperature is secured the left hand lever is raised and the contact is removed from the rivet. After the right hand lever is released a spring pulls back the electrode and this guards against interference with the steel heading tool which is directly above the rivet at all times.



**Rapid and accurate electric riveting is done by this machine**



**Sliding down-hill with a wheel that is firmly locked against rotation**

### Locking the Wheels to Go Down-Hill

A NOVEL and simple device is used by a San Francisco drayage concern in locking the rear wheel of a heavily loaded wagon in going down the steep streets in that city. The device consists of a flanged piece of metal bolted to a heavy steel shoe. The wagon wheel is kept from moving off the shoe by the flanges. The forward part of the steel shoe is slightly inclined upward, with two slits about 2 inches apart and about 5 inches long. This section of the shoe was then raised and a heavy link inserted as shown to the right in the photograph.

A chain running from the front of the wagon is connected to this link. This device is much more efficient and a great deal safer than the usual method of locking the rear wheel by attaching a chain to the spoke and rim of the wheel.—By *C. W. Geiger.*

### Featherweight Phonograph

THERE is something new in the world of phonographs. A machine has recently been perfected with a weight of but four pounds that produces a tone quality comparing favorably with much larger instruments. The machine plays a ten-inch record and has controlling levers for tone and speed. The horn is made of a fiber board and can be easily removed for traveling. The regular needles provided for larger instruments are used on this smaller machine. The base is made of metal neatly finished in black enamel, is narrow and has a length of about twelve inches. Within the base is a double-action spring that furnishes power for the motor.—By *K. H. Hamilton.*

### How Hard Did It Hit?

A RECENT article described an impact-tester designed by the Bureau of Roads for testing the ability of road surfaces to stand up under hard pounding. But road testing surfaces are not the only things that receive blows, nor are heavy blows the only ones that it may be desired to measure.

For instance, the Department of Agriculture has demonstrated that it is profitable to pick most small fruits in the early morning while it is still cool. The Department's tests have shown that when cool the skin of the fruit is considerably tougher than when warm and less easily bruised. The apparatus for these tests consists of an upright metal standard from the top of which an arm projects to one side, supporting a sensitive coil spring. Attached to the lower end of the latter is a metal rod that passes through a glass tube, the tube being held in place by an arm attached to the upright. A hair-line on tube and rod makes it possible to determine the point at which the tension on the spring balances a given weight. At the lower end of the metal arm a glass rod is attached to which is cemented a small glass needle with a rounded end.

To operate, the fruit is placed on the stand in a holder, and the adjustment made so that the surface of the fruit just comes in contact with the tip of the glass needle when the two hair lines coincide. The tension on the spring is released by means of a rack-and-pinion adjustment, permitting the standard to telescope slowly. The operator is able to tell the instant at which the lessened tension permits the needle to puncture the fruit, since movement of the needle is indicated by movement of one of the hair-lines, easily seen because it destroys the coincidence of the two lines.

**A four-pound phonograph of good tone**

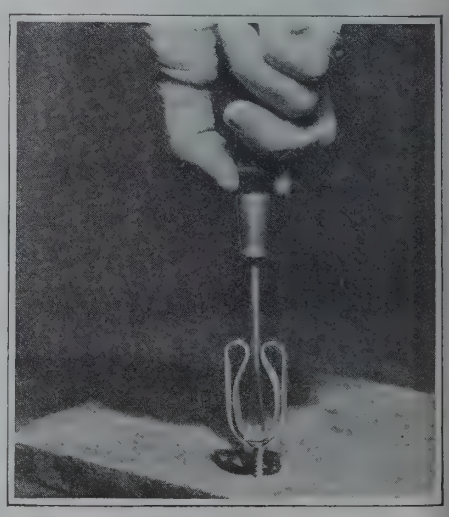
A rather different impact tester is to be found in the Forest Products Laboratory, which has been engaged in a series of tests to determine the relative value of varying species of wood in the construction of airplanes, the resistance to decay as revealed by penetration tests being the determining factor. Port Orford cedar takes first place for its durable quality, while Southern cypress and California redwood are substantially resistant to decay. Douglas fir, white oak, and black walnut proved to be of durable quality.

**Two styles of impact testers used by the Government**

Formerly, the short-lived existence of airplanes rendered the subject of decay immaterial. With improved construction and minimum accidental breakage of airplane parts, the growing needs of replacement because of decay brings to the foreground the relative resisting powers of different species of wood. For instance, spruce timber, the favorite wood for aircraft, is less durable than a dozen other species, according to the government experiments. Basswood, beech, birch and maple are classified as being unable to withstand the powers of decay, with which all mundane things are more or less influenced.

### Driving Screws with One Hand

THE one-handed man will find no difficulty now in driving screws, and his two-handed brother will be able to operate the screw-driver in bad corners where there is no room for a holding hand—there's a place like that on the starting-motor housing of this year's small automobiles. This device, made from spring steel, is so shaped that its fingers hold a screw in place on the end of a screw driver. The upper part of the screw-holder steadies and holds the driver.



**One-hand screw-driver, for use by cripples or in bad corners**

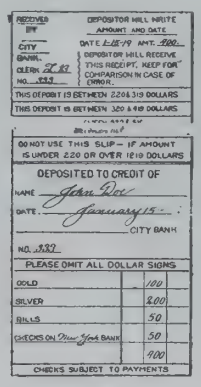
# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

## Of General Interest

DEPOSIT SLIP.—N. E. GOLDBERG, 22 E. 89th St., New York, N. Y. The object of this invention is to provide a deposit slip for use by depositors in depositing bills, coins, checks, coupons and like monetary valuables in banks



A FACE VIEW OF THE DEPOSIT SLIP

and arranged to provide the depositor with a receipt of approximately the amount deposited in addition to the usual entry of the exact amount in the pass book. Another object is to permit the bank of deposit to readily trace any error that may have been made by the receiving teller in the transaction.

DEVICE FOR USE IN BUYING ICE.—J. T. GILBERT, De Funiak Springs, Fla. The invention while adapted for other purposes is more particularly intended for use by a householder in the purchase of ice. The invention especially relates to a device adapted to be placed at the exterior of a house, whereby a coin, ticket or equivalent may be deposited in a receptacle, and a signal displayed bearing numerals indicating the quantity of ice desired; means are provided for locking the device, the signal being automatically removed from display by the raising of the cover of the coin receptacle.

AERO SUBMARINE TORPEDO.—E. A. RIDER, Westbury, L. I., N. Y. The particular object of the device is to provide a high explosive device adapted for dropping from aeroplanes in attacks upon submerged submarines. Among the objects is to provide a torpedo comprising a body with a heavy point

A VERTICAL LONGITUDINAL SECTION, WITH PARTS IN FIRING POSITION

and having its base portion charged with an explosive and equipped with means which after the torpedo enters the water will have a tendency to retard the speed of the projectile, effecting the firing of the charge at a certain determined depth beneath the surface of the water.

SIGNAL POST.—W. O'TOOLE, 1943 E. 30th St., Lorain, Ohio. The object of the invention is to provide a signal post which is of rubber or other suitable material, which if struck by a vehicle will not injure the post or the vehicle, and which is capable of a bending movement with sufficient elasticity to return the post to normal position when permitted, and which when struck will sound an alarm.

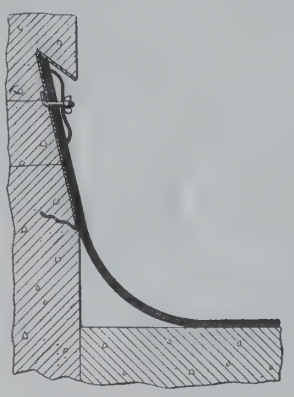
SKIMMING SPOON.—C. F. BEAUFRERE, Central Islip, N. Y. The invention relates generally to skimming devices, and more particularly to a device for removing one of two liquids of different specific gravities which though together are not chemically mixed, the object being the provision of a simple inexpensive device for this purpose which may be readily manufactured of material having a known specific gravity greater than one of the liquids but less than that of the other liquid.

HINGE FOR ARTIFICIAL LEGS.—R. R. DODE, Box 1105, Honolulu, Territory of Hawaii. An object of the invention is to provide a hinge construction with a soft and yieldable pad buffer or stop which will render the closing operation of the hinge soft and resilient, eliminating all closing sounds. The device while particularly intended for use in connection with artificial limbs, may be used in various other ways; it can be built in various forms and designs.

TORPEDO CAPTURING AND DESTROYING NET.—E. KOHLER, Box 3, Alameda, Cal. The invention has reference more particularly to a net which may be cast from a ship and vertically presented in the path of an approaching torpedo to intercept the torpedo in its travel toward the vessel. The primary object is to provide a guard against submarine attacks. A further object is to so construct the guard that it will not only prevent the torpedo from reaching its goal, but the device is capable of also destroying the torpedo.

WALL FLASHING.—W. L. HAWLEY, 2007 E. Washington Ave., North Little Rock, Ark. An object of the invention is to provide a construction of wall flashing which will prevent possibility of leaking at the joint covered by

AN ENLARGED VIEW IN VERTICAL SECTION,



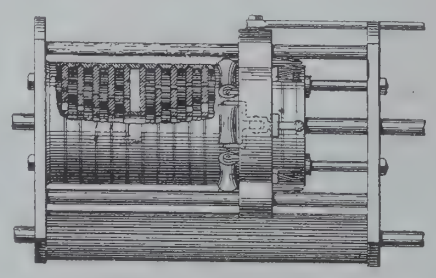
SHOWING THE FLASHING

the flashing. A further object is to provide a wall flashing especially designed for reinforced concrete building structures and which can be anchored in the wall as the latter is built, and which will be comparatively cheap to install and efficient in the performance of its functions.

## Machines and Mechanical Devices

SPRING MOTOR.—O. E. BOAS, 410 No. 5th St., Fort Smith, Ark. The invention has particular reference to means for receiving and holding a coil spring wound to facilitate the insertion of the original within the drum, and to permit of the removal of such spring when broken or otherwise injured and requiring the insertion of a new spring. A further object is to provide means simply constructed, cheap to manufacture and convenient in use.

VARIABLE SPEED TRANSMISSION MECHANISM.—H. G. ALTVATER, 1015 W. 14th St., Denver, Colo. The object of the invention is to provide a variable speed transmission mechanism arranged to permit the operator to quickly and easily change from one speed to another without danger of stripping gear



A PLAN VIEW OF THE VARIABLE SPEED TRANSMISSION MECHANISM

wheels. Another object is to provide a large number of different speeds, say ten for forward drive and five for reverse drive, thus permitting a gradual instead of an abrupt change from high speed to low speed or vice versa thereby rendering it possible for the engine to maintain a practically constant speed.

MEANS FOR LUBRICATING MACHINE TOOLS.—W. F. MCCARTY, Defiance Machine Works, Defiance, Ohio. The object of the invention is to provide means for lubricating the drill spindle, the driving and feeding mechanism for the drill spindle, the speed changing mechanism, and simultaneously supplying lubricant to the drilling tool in the work on the work bed. Another object is to insure a continuous feeding of the lubricant, and to permit of using the lubricant over and over again, thus reducing the waste to a minimum. A further object is to permit the use of a completely closed casing to prevent dust and accidents from the moving parts.

## Medical Devices

MEDICAL APPLIANCE.—W. J. DOYLE, 5804 17th Ave., Brooklyn, N. Y. Among the objects of the invention is to provide a medical applance especially adapted for use by bedridden patients, such device being secured in operative position without liability of becoming displaced, or the contents of the receptacle being spilled, but which may be readily cleaned, thereby making the same sanitary in every respect.

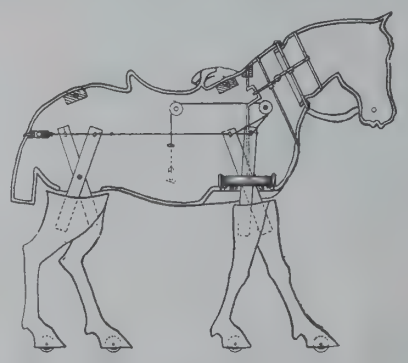
RUPTURE PAD.—T. PACHALI, SR., 232 No. 10th St., Reading, Pa. An object of the invention is to provide a pad which comprises two members movable toward each other to exert a pressure on the tissues. A further object is to provide a pad which can be utilized to grip the flesh directly or a covering or portions of the clothing over the same, and which will retain its position after adjustment. The device may be utilized in connection with any approved form of belt.

## Prime Movers and Their Accessories

SPARK GAP CONTROLLING DEVICE.—G. H. TABER, 182 State St., Binghamton, N. Y. This invention relates to sparking devices for internal combustion engines or the like, and has particular reference to means for varying the intensity of the spark by positive means under the control of the operator. The primary object is to provide means whereby the gaps in all or any number of spark circuits may be increased or diminished at will and so maintained either during the starting of the engine or its subsequent operation.

## Pertaining to Recreation

WALKING TOY HORSE.—A. H. LOOMIS, Les Cruces, N. M. This invention relates to amusement devices and has for its object to provide a toy horse with means whereby its legs may be moved by an operator seated upon



A LONGITUDINAL SECTIONAL VIEW THROUGH THE DEVICE

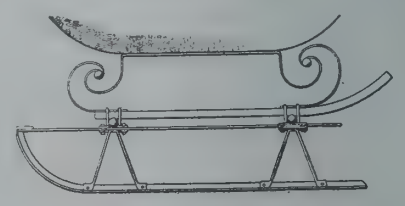
the horse whereby the device will progress with a walking action. An important object is the provision of a toy horse in which the head is swingable laterally to effect steering, connection being provided between the head and the front legs whereby they may be turned without interfering with the walking action.

MARBLE SHOOTER.—A. E. MADISON, 118 Myrtle St., Redlands, Cal. This invention while capable of discharging various projectiles for different games is more particularly intended for embodiment in a device for shooting the taw in playing marbles. The general object is to provide a shooter presenting a seat for the article to be projected and provided with handles to be grasped for holding the shooter and a spring for exerting a projecting force, together with means to contol the spring and to release the same for the projecting movement.

## Pertaining to Vehicles

SHOCK ABSORBER.—T. DAVIS, R.F.D. No. 1, Mounds, Okla. Among the principal objects of he invention is to provide a shock absorber so constructed as to resiliently suspend the springs of a vehicle in such a manner as to relieve the springs of a portion of the road shocks, by the provision of a device wherein compression and rebound occur without danger of breaking the vehicle or the shock absorber springs.

SLEIGH RUNNER ATTACHMENT FOR VEHICLES.—B. FISCH, 403 Chester St., Brooklyn, N. Y. The object of the invention is to provide an inexpensive attachment for vehicles,

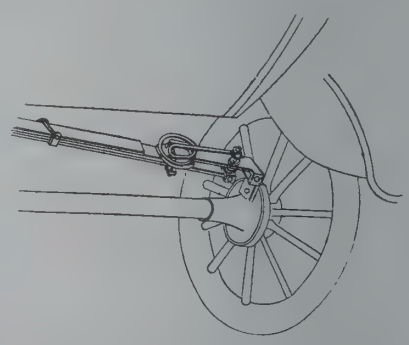


A SIDE ELEVATION OF THE DEVICE, AS ATTACHED TO A BABY CARRIAGE

especially baby carriages, having two runners with means by which they may be quickly and easily mounted on the axles of a vehicle and be secured in position relatively thereto.

TIRE PROTECTOR.—L. F. PETEY, 324 Lincoln St., Rhinelander, Wis. The invention has for an object to provide a construction wherein the resiliency of the pneumatic tire is retained while a thorough protection against puncture is secured. Another object is to provide a protector formed into a plurality of parts and connected together in such manner that it will not interfere with the usual resilient action of the tire.

SHOCK ABSORBER.—T. DAVIS, R.F.D. No. 1, Mounds, Okla. This invention relates to attachments for motor vehicles and has for its object the provision of a shock absorber for use upon motor vehicles of a very popular make provided with transverse front and rear springs, the device being in the nature of



A PERSPECTIVE VIEW, SHOWING THE DEVICE AS APPLIED TO ONE END OF THE REAR SPRING

a coil spring including a plurality of horizontally disposed convolutions, novel means being provided for connecting the device with the rear hubs or with the front axle as the case may be.

RIM HOLDING STAND.—P. CANNON, 36 W. 66th St., New York, N. Y. The invention relates to means for facilitating the removal of a shoe or tire from a rim and more especially to a device particularly adapted to be used with a rim of what is commonly known as the detachable, demountable type. The object is to provide a foldable rim holding stand arranged to support a rim a short distance above a floor to facilitate the removal of the shoe, the device being readily adjustable to accommodate different sized rims.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

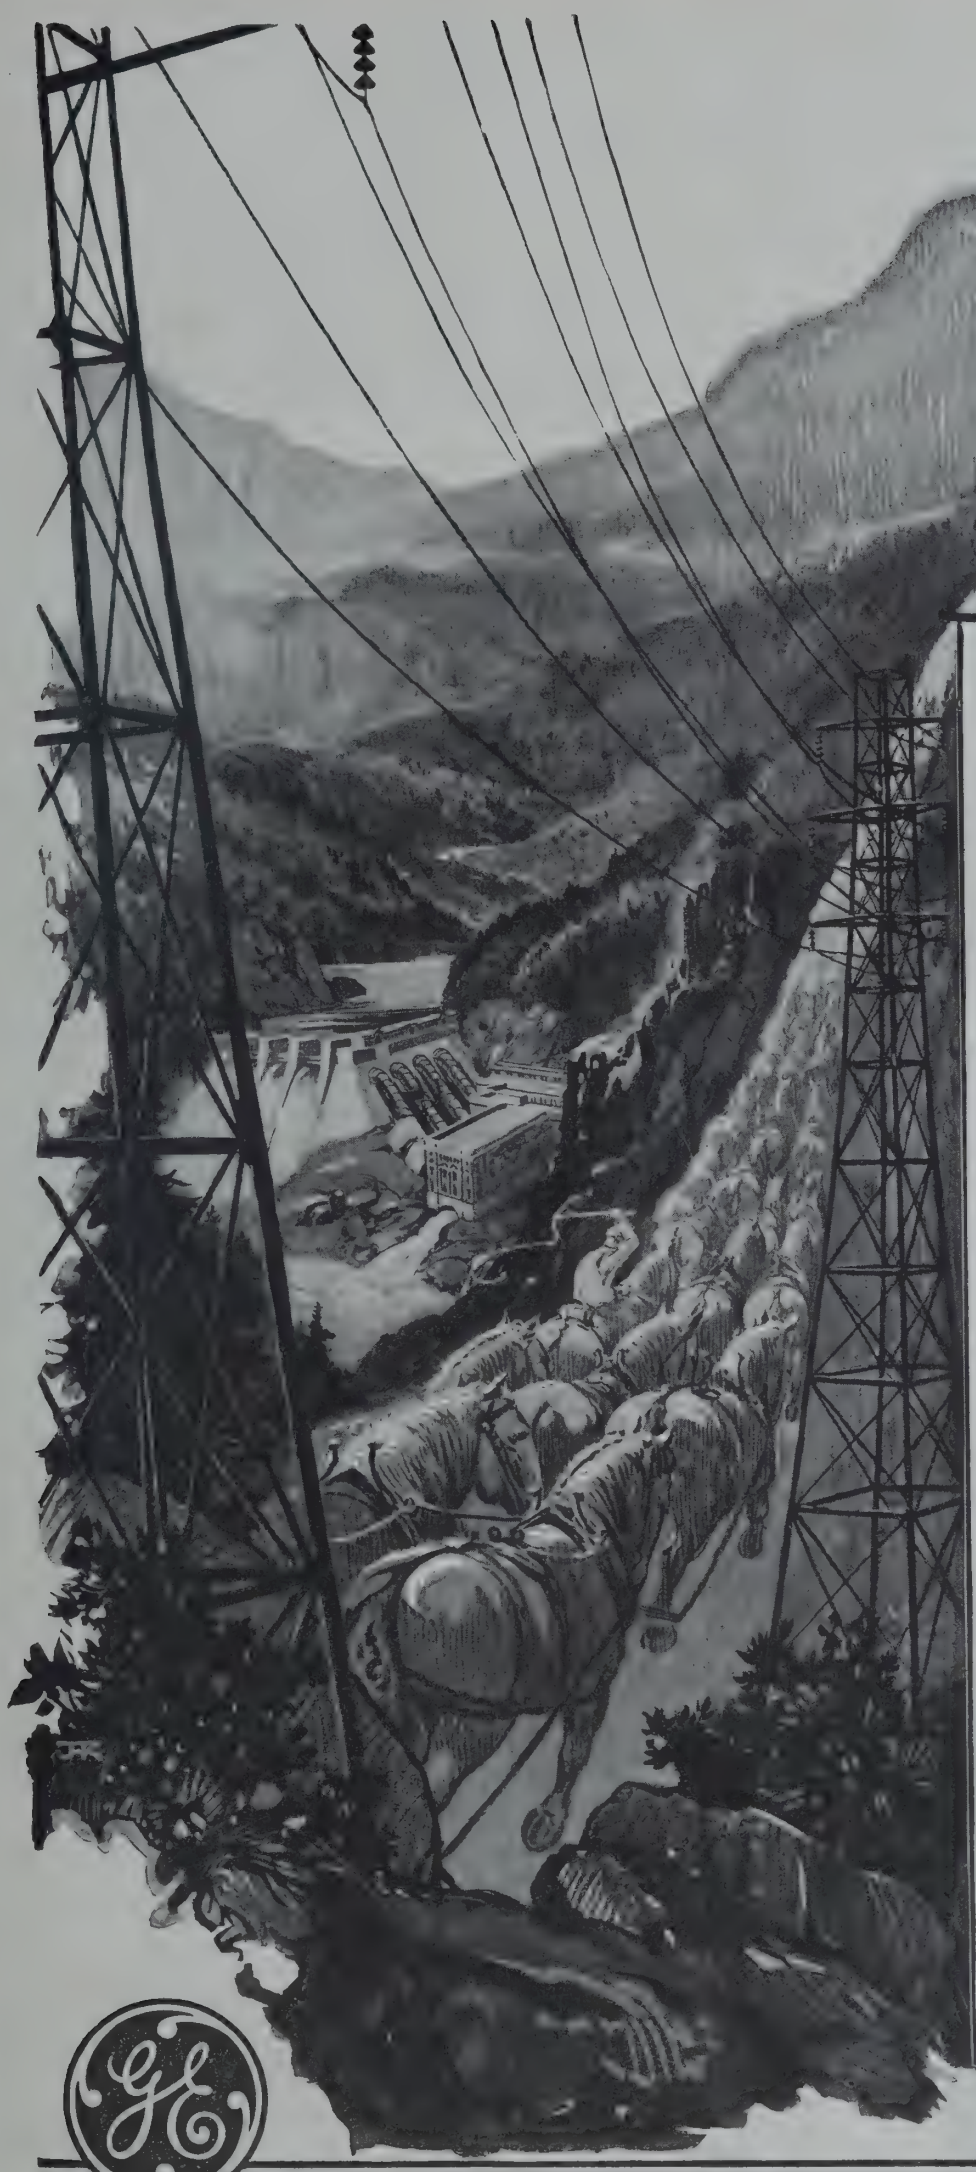
Hobart Building, SAN FRANCISCO, CAL.



## *Sending horse-power world-wide through a wire*

AT six o'clock in the evening a switch is closed and the streets of Los Angeles become broad avenues of light. At the same time, a little village a hundred miles away is made safe for the night by the glow of electricity. And the same source of power supplies them both.

Far up in the hills is a power plant, where big smooth running machines silently change the rush of a waterfall into the invisible power that runs through a wire and does the work of man *wherever he needs it, whenever he wants it, no matter how hard that work may be.*

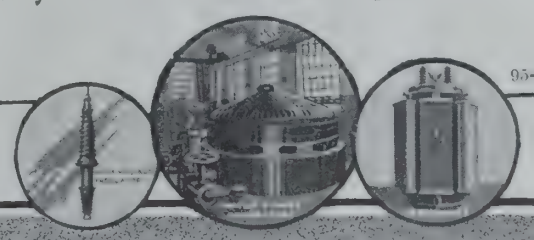
Whether it be to drive the wheels of big industry, to carry people and materials across continents, to propel a ship at sea, to save the housewife work and worry, or to furnish the same good light for the rich and poor alike—electricity is always available, for it can be carried from the place it is made to the place it is used, quickly, cheaply, safely, in any amount.

The same system of wires may be fed by a coal mine in Pennsylvania and a waterfall in Maine, and may supply a power line which serves a spinning mill in Massachusetts and the water pump of a Delaware farmer.

The people of several states derive benefit, pleasure and protection from one power plant on the Mississippi at Keokuk, Iowa. The falls of Niagara serve thousands of communities in New York State and Canada.

The General Electric Company has not only provided a means for developing nature's dormant resources into power. It has also perfected the necessary machines and devices for sending that power to the places of greatest usefulness. These machines regulate the intensity and pressure of that power; protect the lines from lightning and make it easy to distribute 50,000 horse-power in fractions of a single horse-power, without danger to equipment or user.

But the greatest service of the General Electric Company is its increasing usefulness, both in the origination of new machines for new uses, and in the whole-hearted employment of its vast organization towards making electricity a commodity which may be made cheaply, transmitted easily and used intelligently by the masses, from school boy to engineer. And in doing this, the General Electric Company is constantly striving to conserve raw materials, such as fuel, which may better serve man in other capacities



95-173

GENERAL ELECTRIC COMPANY

# Jim Wanted to Earn More —

Jim was the "belt man" at the Millard Mills.

Ambitious enough to want to see more money in his pay envelope each week. Yet *intelligent* enough to know that to *get more*, he must make himself *worth more*.

And just there was the "rub."

Kept on the jump every minute of his working day—rushing hither and yon to *remake* belt joints that didn't, wouldn't and apparently couldn't "stay put"—Jim found little or no time for really constructive work—work that would have increased his earning power and his *getting* power. He was in a rut—and he knew it.

It was then that he heard of Crescent Belt Fasteners—heard how they dispelled belt troubles once and for all by making a joint that "stayed put."

Jim was incredulous—but desperate. He determined to give Crescents a trial. Did so. Found that what he had heard was Gospel Truth. The joints he made with Crescents H-E-L-D with a won't-let-go grip. No part of the belt was punched or cut away—its full strength was sustained. Perfect contact with pulley at the joint insured full power transmission. Freedom from the interruptions caused by non-holding joints meant continuous production.

And now Jim is a different man.

Freed from the worry and work of continually remaking belt joints, he has time to apply himself to productive, constructive work—to make himself *worth more* to Millard Mills.

Furthermore, the Big Boss has noticed the difference in Jim. And has made a corresponding difference in the amount he puts in Jim's weekly pay envelope.

Is there a moral in this for you?

If so, we suggest that you write to Dept. 66 for new Booklet on Increasing Belting Efficiency

## Fish Fancying and Freak Farming

(*Continued from page 31*)

their fate and never revisits the spot.

With the approach of cold weather, the adult terrapin begin to get inactive and ultimately burrow into the mud and hibernate until warm weather again rolls round. Left to themselves, these turtles hibernate in deep water or in holes which they dig along the shore a few inches under the low-water mark. Where the turtles are raised in confinement the customary practise is to provide a board shelter which is sunk and fastened to stakes about one foot above the bottom of the pound in some protected corner of the inclosure. Generally the fish shed is bedded with eelgrass, a shelter three by five feet in size furnishing ample bedroom facilities for the winter sleep of 100 to 200 full grown turtles where they arrange themselves in layers, as they ordinarily do.

It is a relatively easy and simple matter to care for adult terrapin while their feeding expenses are practically negligible as it only costs seven to eight cents a day to feed 100 animals. Under natural conditions, the diamond-back terrapin is omnivorous, feeding on smaller crustaceans and mollusks and consuming, in addition, considerable vegetable matter. Under domestication, chopped, fresh fish is one of the best foods for the aquatic turtles, the average adult consuming about two ounces daily. Blue crabs or fiddlers may be used as a change feed to lend variety to the menu where they are available while oysters are the preferable food for the young turtles which are forced during the season of cold weather in the hothouse. The common practice is to feed unmarketable and small-size fish to the terrapin. Under conditions where a dependable supply of fresh fish was not obtainable, cornmeal has been fed in a soft mash form while sliced and mashed cabbage and turnips have also been successfully used.

Terrapin farming features two avenues of income, as foundation breeding stock can be sold to persons who wish to engage in the business in addition to marketing the mature turtles for human consumption in Baltimore, Philadelphia and New York, the leading terrapin centers of the country. As the annual losses consist of less than ten per cent of the first brood and a mortality of less than one per cent a year in the case of the full-grown terrapin, the income from the commercial production of these valuable and sought-after products promises to be fairly certain and dependable. It is essential to keep the pens and pounds clean and free of contamination. Usually the water flow will carry away any debris and where only chopped fish is fed there ordinarily is no aftermath left to be removed. It is necessary to maintain the winter house for the young in a neat, sanitary condition and where these requirements are satisfied, the terrapin raised under confinement are protected from all the evils and ailments to which the animals are exposed under natural conditions with the results that sickness and mortality are reduced to a minimum.

## The Twentieth-Century Lumber-Jack

(*Continued from page 34*)

These are driven into the cut, back of the saw. They keep the tree above from throwing weight on the saw and thus causing it to "bind" and they also assist in directing the fall. After a time, there comes a critical moment when the tree really starts to fall. This occurs when a part of the bole is still untouched either by notch or by saw cut. The sawyers must be on the alert. It is necessary to stay long enough, and it is inadvisable to stay over long. One man simply lets go and makes his "get away"; the other must get the saw out and then get out of the way.

Before quitting the felling of trees, it may be of interest to show how the lumberman uses peavey and kilhig in directing the fall. The kilhig is a long pole, perhaps 3 or 4 inches in diameter. At one end it is sharpened or else shod with a pointed tip or fitted with a spike. This end is set in a small notch in the tree at a point anywhere from 5 to 8 feet above the ground; while the other end rests against a peavey handle or short pole. The peavey or pole is stuck in the ground like a crow-bar and is in contact with the kilhig a short distance above this point of support. By thrusting the upper end of the peavey or pole forward, the whole acts as a lever, the fulcrum being at the ground level. By this means a very strong thrust may be exerted against the kilhig and so against the bole of the tree.

The great tree may be comparatively alone so far as big companions are concerned; but there may nevertheless be quite a woods around. He crashes down, woods or no woods, crushing and breaking everything in his way. His branches are to be cut away and his bole cut into log lengths. This latter is called "bucking" the tree. Here the cross-cut saw has largely displaced the axe.

The cable-way is coming into greater and greater use in logging operations. Its principal function at present is concerned very largely with the getting of the logs from the scene of the felling to points along the road over which they are to be hauled. Essentially, the cable-way consists of a sufficiently heavy wire rope temporarily suspended between elevated supports, a carriage adapted to travel on this rope as on a track, and sheaves and tackle suited to shift the empty or loaded carriage along the cable. This cable needs to be a strong affair as it must ordinarily support the log or logs. A wire-rope 1 or 1¼ inch in diameter is the usual thing. The span may be 600 or 750 feet, or even longer. A representative method of arranging matters is as follows: Along the road over which the hauling is to be done, and at intervals of perhaps 1,000 feet, head trees are selected. Back in the region to one or both sides of the road, tail trees will also be chosen. Intervals between them of 150 or 250 feet are representative. These tail trees will roughly parallel the road and the line of head trees. A cable-way will cover the ground between a tail tree and the nearest head tree. It will readily be seen that in some positions, the cable-way will be perpendicular to the road and at other times more or less oblique. The logs are secured, naturally, in the regions commanded by the cable-way positions and brought in to the head trees by operating the carriages.

The head trees are selected for size, height and straightness as well as convenience of position. A good head tree may be 18 inches in diameter 60 feet from the ground. Steel guy ropes are used as a means of maintaining head and tail trees. It is necessary that the carriage or trolley shall have two movements—the out-haul and the in-haul movement. Two independent ropes may provide for this double requirement. A hoisting engine will be set up near the head tree. For two independent ropes, it must provide two independent drums or their equivalents. The tail rope may be arranged as follows. It passes from the hoisting engine to a sheave block secured up on the head tree, thence to and through the carriage and on to a second sheave up on the tail tree. Passing round this sheave, it returns to the carriage and is there attached to the rear of it. Naturally, a winding-in movement of the drum will exert an out-haul pull on the carriage. The in-haul rope is known as the skidding rope. It runs from a drum on the hoisting engine to a sheave up on the head tree and thence to a

# The Connecting Link Between

*Economy was the first line using an inexpensive bare link for restoring a blown fuse to its original efficiency to be Approved In All Capacities by the Underwriters' Laboratories.*

second sheave secured to the head of the carriage. This rope may then run back to the head tree. A winding-in movement of the drum, and the trolley is hauled in with its load. The power of the skidding haul may be regulated by the windings on the blocks. Naturally, though, the greater the power exerted thus, the slower the speed. But it is, in mechanical affairs, often the case that what really counts is doing the work whether the speed be slow or fast.

The aerial tramway is a kind of developed cable-way. It is advantageously used in such cases as those where the logs are to be got off of a plateau to some comparatively low point in the valley; and in cases where a reverse transfer is to be made—that is, for example, from a wooded region in a canyonlike valley to some elevated point on the side. In either case, what needs to be done is not necessarily a transportation from the scene of the felling nor a transportation to a main road to the mill. The bridging of the gap, as it were, may occur at any place between the point where the trees grew to a point where they are cut up into lumber. Generally, the tramway lies in one vertical plane. But there may be curves in that plane—depressions and elevations. If the general direction is down, gravity may supply the power for the transportation. The logs are carried, not dragged. Tramways may be quite long affairs. There is one in the South that is 3,700 feet in length. The logs are brought to the brow of a plateau by other means. From this point to a railway in the valley below, they are transported on the ¾-inch steel rope of the tramway. The general slope of the country is followed roughly by the line traced out by this cable in a vertical plane. There are brackets at intervals of 150 and 250 feet which support the line and are in turn supported by the trees to which they are attached. There is a suitable casting belonging to the brackets, and a slot in this casting provides a resting place for the wire rope. The logs are carried by trolleys, two to a log. The cable rested in a slot in the casting without being fastened, except in depressions, where a keeper was secured to the bracket. Each of the trolleys carrying a log was provided with two sheave pulleys. These ran on the upper side of the cable. The logs were secured and held by "grabs." Each grab was attached to a short chain at one end, while at the other a ring was provided. The rings enabled the chains, grabs and logs to be temporarily secured to the two trolleys. Five pairs of trolleys carrying five logs were secured together by a ⅜-inch wire rope which passed around a drum controlled by a friction brake. Naturally, the hoisting engine to which the drum belonged was set up at the head of the incline. It paid out the line connecting the trolleys when they made the descent to the railroad, and wound it in when the load had been discharged and the trolleys and chains were ready for the return. A 15-hp. gasoline engine supplied the power. The logs were brought to the brow of the plateau by horses, after which they went down the inclined cable. This example will answer as sufficiently representative of the use of cable tramways in logging operations. Variations may naturally be made, even to reversal of the direction of movement of the load.

Logging railways have been coming into favor in recent years. These vary much in design, excellence, speed of transportation, and the like. Some roads have tracks whose rails are the natural boles of trees. The limbs are removed and the inner face squared. Such rails may be laid directly on the ground if it is sufficiently hard, although a certain amount of ballasting or blocking up may be needed to get the upper surface moderately level. The motive power consisting of horses, mules or oxen, goes on its feet in the space between rails. After a time

# Enemies of Portable Electric Cord

Sharp edges, heavy tools, castings, trucks—these are the enemies of portable electric cord.

Ordinary cord falls down under such treatment because the cover is weak. For on the cover depends the life of any cord.

**DURACORD**
TRADE MARK

is the portable electric cord with the heavy *woven* covering like a piece of fire hose that stands up under the most grueling service. It will outwear ordinary cords many times, prevent expensive delays and keep down renewal costs.

Duracord can be furnished in all sizes of portable electric cord and also in the larger sizes of single and duplex cable. Ask your electrical jobber about Duracord or let us send you samples of Duracord and ordinary cord for you to test and compare yourself.

# SIMONDS

## CIRCULAR SAWS

*'tis the way they are made*

The SIMONDS method of flattening and tempering under pressure, in one process — and without hammering — is a vital factor in the keen, edgeholding qualities of SIMONDS Circular Saws.

The fact that SIMONDS owns and operates their own Crucible Steel mill, insures steel of the exact analysis desired for every SIMONDS product.

**Simonds Manufacturing Co.**

**SIMONDS** SAW STEEL PRODUCTS MADE RIGHT SINCE 1832

such a railroad may become a kind of shallow trench through the woods. The wheels of the cars may have big circular grooves on the periphery to provide for a proper grip on the rail; or the inner flange may be more pronounced. Then there are railroads where sawed pieces supply the rails. This particular type of road is common in the hardwood regions of the Appalachians. However, the cost of maintenance is considerable, due largely to the wear and tear of the rails, but also to the disintegrating effects of wet weather. Steel rails are in considerable use and have approved themselves over a goodly period. Railroads with such rails may be operated by animal power or by steam locomotives.

### Turning the Wheels of a Century Hence

(*Continued from page 36*)

the country or for a drainage basin. Furthermore, different authorities show a wide variation even for comparatively limited areas. For instance, one authority allots to California 11,400,000 horsepower, another only 5,000,000. One authority gives Oregon nearly 9,000,000 horse-power, another only 3,300,000. One gives New York, Maine, California, Oregon and Washington a total of 31,000,000 horse-power while other authorities give these states a total only half as great.

There are comparatively few distinctively storage developments in the United States. In many engineering problems the engineer can use the actual results of similar work as a basis for estimates, but in computing storage possibilities few if any such results are available. Any estimate including storage, therefore, must be mainly theoretical. Such theoretical computations are likely to give results far in excess of actual possibilities. There are many practical factors that reduce such theoretical power. In the first place, the flow of many streams so fluctuates—that is, the flood is so high and the minimum so low—that a vast storage would be necessary to bring about a reasonably high average of actual power-production. Such storage may be either physically impossible or its cost may be prohibitive, because of the value of the land which would necessarily be submerged. The New York State Water Supply Commission, for instance, found that the flow of the Delaware River varied from as little as 400 cubic feet per second in extreme drought to 150,000 cubic feet at freshet flow, but that there are not storage facilities of sufficient capacity to hold back the vast volumes of flood water. Again, a stream may have a relatively even flow but so gentle a slope as to render storage impracticable; and still again, power and storage developments may be impracticable because of insufficient foundations for a dam. This is the case with the lower portions of the Grand and Muskegon Rivers in Michigan. Storage possibilities are further limited by the increasing demand for water for other uses, such as irrigation and domestic supplies for cities and towns. It is apparent, therefore, that any estimate based largely upon the theoretical possibilities of the topography of a section must be subject to serious practical error.

Summarized, then, the conclusions here reached are that the maximum possible power-development through the use of water power is but a wild guess, but that it is most certainly in excess of twenty-five million horse-power, that it is probably in excess of forty million horse-power and that it is possibly more than double that sum, should great need (as caused by a fuel shortage) make an intensive cultivation of water power a necessity as well as an economical possibility.

With these figures in mind, we can logically proceed to a consideration of those factors which have held this nation back in the development of its water power and the necessary things we, as a nation, must do to make of our power resources as great an economic asset as we have made of our coal and are now making of our oil. Let us hope that when we do, it will be with less waste and extravagance than has characterized our use of fuels, and let us thank whatever Gods control us that our power resources, unlike our forest resources cannot be destroyed by fire or greed for the present gain without regard to the future.

### Measuring Steam

(*Continued from page 37*)

that it is usual to magnify the motion of the mercury by a float and pulley mechanism, thus giving a large motion of a pointer exactly as in the case of the ordinary type of "weather glass." Another device consists in arranging that the column of mercury as it rises shall successively short-circuit a number of resistances through which a current of constant voltages is flowing. By suitably proportioning the resistances it is possible to arrange that the quantity of current flowing at any time is directly proportioned to the quantity of steam flowing. Thus an ordinary ammeter will serve as an indicating instrument, and a wattmeter similarly can be used for recording the total flow. The use of mercury, however, has certain disadvantages, so that other makers cause the differential pressure to act upon a spring-controlled diaphragm, the movement of which is magnified and transmitted to the pointer by means of a series of levers.

In some steam meters diaphragms, similar to those used in aneroid barometers, are employed, and the pressure correction device to which reference has been made above consists of another set of spring-controlled diaphragms subjected to the total steam pressure. The motion of these latter diaphragms is made to alter the leverage with which the differential pressure diaphragms act upon the pointer. The combined action of the two sets of diaphragms therefore causes the pointer to indicate the true quantity of steam which is passing, independently of changes which may take place on its pressure. In addition to recording the rate of flow on a chart these meters may be caused to integrate the quantity of steam which has passed, so that it may be read directly on counting dials. The clockwork mechanism which drives the chart also causes the periodical rotation of a spindle, which is held in gear with the counting mechanism during a part of the revolution, greater or less according to the rate of flow at the time. Other methods of integrating the flow comprise a friction wheel driven by a disk. The disk is rotated uniformly, but the revolutions of the wheel and therefore of the counting mechanism depend upon the radial position of the wheel on the disk. This position is controlled by the rate of flow of the steam.

### Toys That Do Great Work

(*Continued from page 38*)

recorded. It is possible to calculate from this test just what horse-power will be required to drive the completed ship. In the case of yachts or other pleasure boats, the designer often has made a model which will show the prospective owner just how the vessel will look.

Before a skyscraper is built or any other important building, plaster or clay models of it are made to assist the architect in designing the exterior. Interior models are also often made to help in the arrangement.

Models were used in the laying out of some of our huge war munition plants. In one case a model almost large enough to fill a room was made, with every building in detail. It facilitated the problem of arrangement.

Since 1912 the U. S. Naval Academy has used hundreds of models for the instruction of cadets. One model built for the

academy is a full-size Deisel oil engine, cut away to show how every part functions. The firing, scavenge and intake in the cylinder is illustrated by colored lights automatically operated.

It has been found that by the use of models instead of drawings or photographs the task of explaining a mechanism to the student is much simplified. Other nautical schools and in fact, schools of all kinds, have followed the lead of the Naval Academy in using models.

The motorist now can buy models made of cardboard and metal which show him the exact function of every piece of his motor car. In fact, any attempt to catalogue the varied practical uses to which models are put must end in the approved sale-bill style "and other uses too numerous to mention."

The foregoing names some of the more important uses, but overlooks perhaps the most common—that of employing models in the developing of patents. The U. S. Patent Office formerly required that a model be submitted before patent papers were granted. But this practise was discontinued after thousands of models had accumulated and finding storage space had become a problem. But every American citizen over the age of ten years has tucked away somewhere a model of "my invention."

## The Mechanical Hello Girl

(*Continued from page 41*)

scriber it is ready to receive his order by giving him a distinctive buzz called a "dial tone."

As the next step in the manual operation the calling subscriber gives his order verbally to the operator. In the mechanical system the calling subscriber dials his order to the sender by pulling the letters and numerical digits of the number desired, in succession.

Assuming that the call is for another subscriber in the same office, the manual operator gives the desired number to a "B" operator in her own office over the call wires, gets a trunk assigned and extends the calling line to the "B" operator by plugging the calling cord of the pair she has used in answering into the outgoing trunk leading to the "B" position. The mechanical "sender," upon receiving the office code letters from the subscriber dial, recognizes their significance and causes the "district selector" (elevator), which is definitely tied to the line finder previously used, to start up and select an idle path or trunk leading to an "incoming selector" (elevator) in the same office. The analogy is evident between the "calling cord" of the manual system and the "district selector" of the mechanical, as well as the manual outgoing trunk multiple jacks which terminate at the "B" operator's position to the district selector banks which terminate incoming selectors on the incoming frame.

The "B" operator locates the desired subscriber's number in the multiple before her by first locating the hundred, then the strip, then the particular line. She then tests the line to see if it is busy. If it is not she inserts the incoming trunk into the multiple jack and ringing is started automatically. If the line had been busy, she would have inserted the trunk plug into a "busy back" jack. The mechanical step corresponding to all this is when the "sender" causes the incoming selector to locate the group of trunks leading to the particular 500 lines in which the desired number is located. This causes a non-busy trunk to be selected and then causes the "final selector" (elevator) on the end of that trunk to locate the hundred, then the ten and finally the particular unit line desired. The "final selector" tests the line to see if it is busy, and if it is not establishes the connection. Ringing is started automatically. If the line is busy the connec-

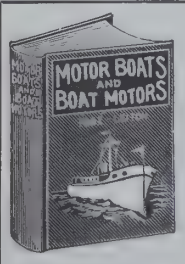
A New, Complete Book for Owners' Uses, Repairmen and Operators



**Motor Boats and Boat Motors**

DESIGN—CONSTRUCTION—OPERATION—REPAIR

Written by a corps of experts, edited by
VICTOR W. PAGE, M.E.

524 Pages (6x9), 372 Specially Made Engravings and Complete Working Drawings
Price, $4.00; by mail, $4.20

THIS is a complete handbook for all interested in any phase of motor boating, as it considers all details of modern hulls and marine motors, deals exhaustively with boat design and construction, design and installation of all types of marine engines and gives expert advice on boat and engine maintenance and repair. Not only is boat construction fully treated but every needed dimension is given for building from complete, yet simple plans and construction is considered step by step. Everything from the selection of the lumber and laying out the boat molds to the finish of the completed craft is outlined in detail. The boats described have been built by the author and the plans are right. The book has also

A Special Chapter on Seaplanes and Flying Boats

SCIENTIFIC AMERICAN PUBLISHING CO., 233 Broadway, New York

tion is not established and a "busy signal" is sent automatically back to the subscriber. The analogy between the subscriber's multiple on a manual "B" board and the combination of the incoming and final frames, while not perfect, is still rather striking.

No attempt has been made here to describe the intricate machinery which accomplishes the remarkably human results. They represent years of work on the part of many trained engineers and it would take volumes to describe them adequately. Neither has it been explained how all of the supervising, timing and ticketing of various classes of calls is accomplished. It must suffice, in the limited space available, to say that it is done and with much less error than occurs when these same operations are performed by human hands and brains.

While other improvements will undoubtedly add to the utility and economy of the automatic telephone, the instrument has now reached a stage of perfection where the large telephone companies are willing to invest millions in such equipment, and have already begun installations which will eventually cover the entire continent.

Of course most of these momentous changes will go on so gradually and with so little friction that the average man will not realize their significance. He will have his desk phone equipped with a dial and he will find the telephone numbers in the directory listed with the first three letters of the exchange name in capitals. He will find his service better, but he will take it all for granted and will worry his head very little over how it's done. But to the man who takes the trouble to investigate, this new development in modern science will be a never-ending source of wonder.

## The Rôle of Asbestos

(*Continued from page 42*)

contaminate the original composition of the fluid.

Asbestos has a very wide adaptation in the automobile field, for, in addition to the already enumerated uses, which are of course found for it in automobile factorise as well as elsewhere, it is used in wood form for the construction of enameling ovens and in other places requiring a structurally strong fire- and acid- proof material. Asbestos is particularly valuable in the actual operation of the automobile itself, as a gasketing material for cylinder heads and intake and exhaust manifolds; as spark plug packing, clutch facings and protective tubing for the electrical wiring; and in some cases in the manufacture of the tire fabric. Then the greatest use of all for asbestos in automobile operation is for brake-band lining, the production of which is approximately fifty million feet per year. The longest fibers are required for brake band lining and textiles. On account of its high coefficient of friction and resistance to heat and wear it is also chosen for brake drums on hoisting-engine cranes and like apparatus.

The familiar uses for asbestos in the home are the insulation of furnaces, steam and hot water pipes, hot air ducts and as a stove lining; as table covers, table mats, flat-iron holders and rests and fiber for gas logs; as a fireproof material for ceilings, walls, partitions and baseboards; and as stucco or roofing for the home, barn, silo or garage.

A list of the possibilities of asbestos is far from being exhausted by packings and heat insulations in the industrial field. The architect and engineer are further indebted to it for the safer, better and easier construction of fireproof buildings which its use in the forms of asbestos wood or "lumber," waterproofing felts and roofings has made possible. The variety of present uses in the building of business structures and homes indicates the almost unlimited range of possibilities for this mineral in building construction.

Asbestos wood is remarkable in many ways. It is comparatively light in weight; structurally strong and practically everlasting. It can be "worked," fastened and painted like ordinary woods but unlike them it does not warp or crack in service. It is all the more remarkable because of the positive fire-protection it affords with a minimum thickness—as against brick tile and other materials—thereby saving valuable floor space. It is widely used as a fire barrier in walls, partitions, doors and ceilings in hospitals, libraries, depots, public buildings, residences, foundries, warehouses, machine shops, garages and almost every other type of building. In this application it takes the form of roofing, sheathing, window casing, moldings, cabinets, tank linings, flooring, and battens. For electrical purposes asbestos wood plain or impregnated is less absorptive, has greater dielectric strength, is lighter in weight, has greater insulation resistance, and is structurally stronger than competing materials; it will not crack under the highest voltage.

Asbestos is recommended for use as disconnecting switch bases for lightning arresters; primary fuse boxes; terminal blocks on motors and generators; panels for switchboards; switch barriers; faces for all kinds of rheostats; electric elevator controls; cabinets for distant control of oil switches; converter panels; busbar supports; and for many other places in the manufacture and uses of electric equipment.

Next to the heat-insulating and packing field the greatest use for asbestos is in the manufacture of fireproof roofings and shingles. Its inherent durability and immunity to fire and atmospheric conditions make it the ideal material for this purpose because of the protection from roof-communicated fire it affords both the individual and the community. The standard forms of asbestos roofings are, first, asbestos shingles, composed of asbestos fibers and Portland cement pressed together and cut to size and shape, and invariably used in the construction of homes and residences. Then there is asbestos felt roofing, made of asbestos felts cemented together with asphalt and shipped in rolls, and used both as a roofing material and in waterproofing the foundation walls of industrial and office buildings and similar structures. Finally, corrugated asbestos roofing, in which the asbestos felts are cemented to both sides of a sheet of corrugated steel to serve as a protection against rust and corrosion, is used on foundries and industrial buildings over skeleton frame construction as a roofing and siding.

Even in the theater asbestos is absolutely essential. In the curtain it serves as an armor against fire and the dangerous backdraft. Scenery is made from asbestos and the lights, both in the theater and home, are energized from distant generators through a system safeguarded by this same material. In the moving picture theater, which today is a recognized part of our social life, the patrons are protected from the spread of fire from the inflammable film by an asbestos-wood projecting booth. At the warehouses of the film distributors these highly inflammable films are stored in racks and cabinets made of asbestos wood.

Asbestos today is an industrial, architectural and domestic necessity in the strictest interpretation of that word. There is no substitute for it. No other known material possesses the inherent fire resistance, durability and adaptability of asbestos. It can be woven, spun, pressed, matted, molded, in fact made up in almost any form, either alone or in combination with other materials to produce the desired results. And what is very important, it readily combines with almost any material because it offers no chemical or physical reaction.

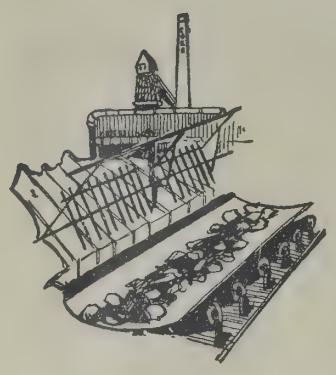
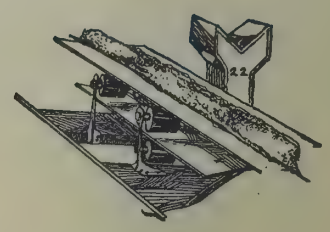
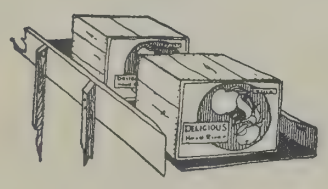
# "Convey by Belt"

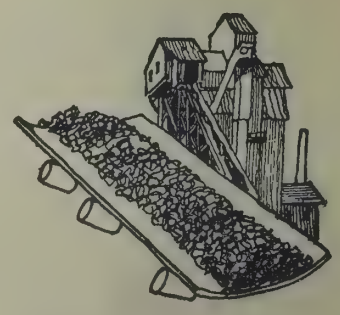


THE progressive man does not transport his raw material or finished product by wheelbarrow or hand when railroads or motor trucks are available.





Yet within his own plant there are relatively short hauls where conveyor belts can handle materials in greater volume and more economically than hand labor.



Our engineers who specialize on conveyor belt problems will demonstrate upon request how you can secure greater production at lower cost when you "Convey by Belt."

# PAIGE

*The Most Serviceable Truck in America*

# MOTOR TRUCKS

It is unquestionably because of their rugged construction and enduring stamina that Paige trucks are proving themselves so eminently fitted to the needs of inter-city transportation.

On numerous motor express lines—notably on the well known Mason City route in Iowa—they are daily demonstrating their sturdiness and stability by the regularity with which they maintain exacting schedules.

The uniform dependability which Paige Trucks are exhibiting in this latest and most severe type of truck transportation may be taken as a reliable criterion of the service which Paige trucks render in all lines of truck transportation, city as well as rural.

# The Square marks the spot where the escape was made

RIGHT through steel plates, mocking the rivets, without noise or clue, one thousand pounds of coal escaped from within this chalked square last year. It escaped as valuable heat bought and paid for—horse-power that never did a tap.

Now a square foot isn't very large, just large enough to suffer being overlooked in the average place where heat is used. But when you add up the small isolated areas, fractions of square feet in a power plant or factory, or even in a cellar heating plant, the total is enormous. It stands as wasted coal, more often amounting to tons rather than pounds.

In money it is often staggering, and so unnecessary because so readily corrected if intelligent knowledge of insulation is called in to correct it.

From the buyer's viewpoint, an insulation service should be able to answer this basic question: How much money return, based on heat savings, can I expect through an investment in insulation of this or that kind?

It is the answer to this that Johns-Manville Insulation Service is able to provide.

Through scientific investigation controlling manufacture and application of insulations, any condition can be met and corrected with certainty and savings computed even before the work is started.

Insulation is one of the most important departments of our business, and has been for over fifty years. Today this is a national service, not only completely equipped with materials for every industrial condition, but including as well contract departments in all our Branches for the application of these materials.

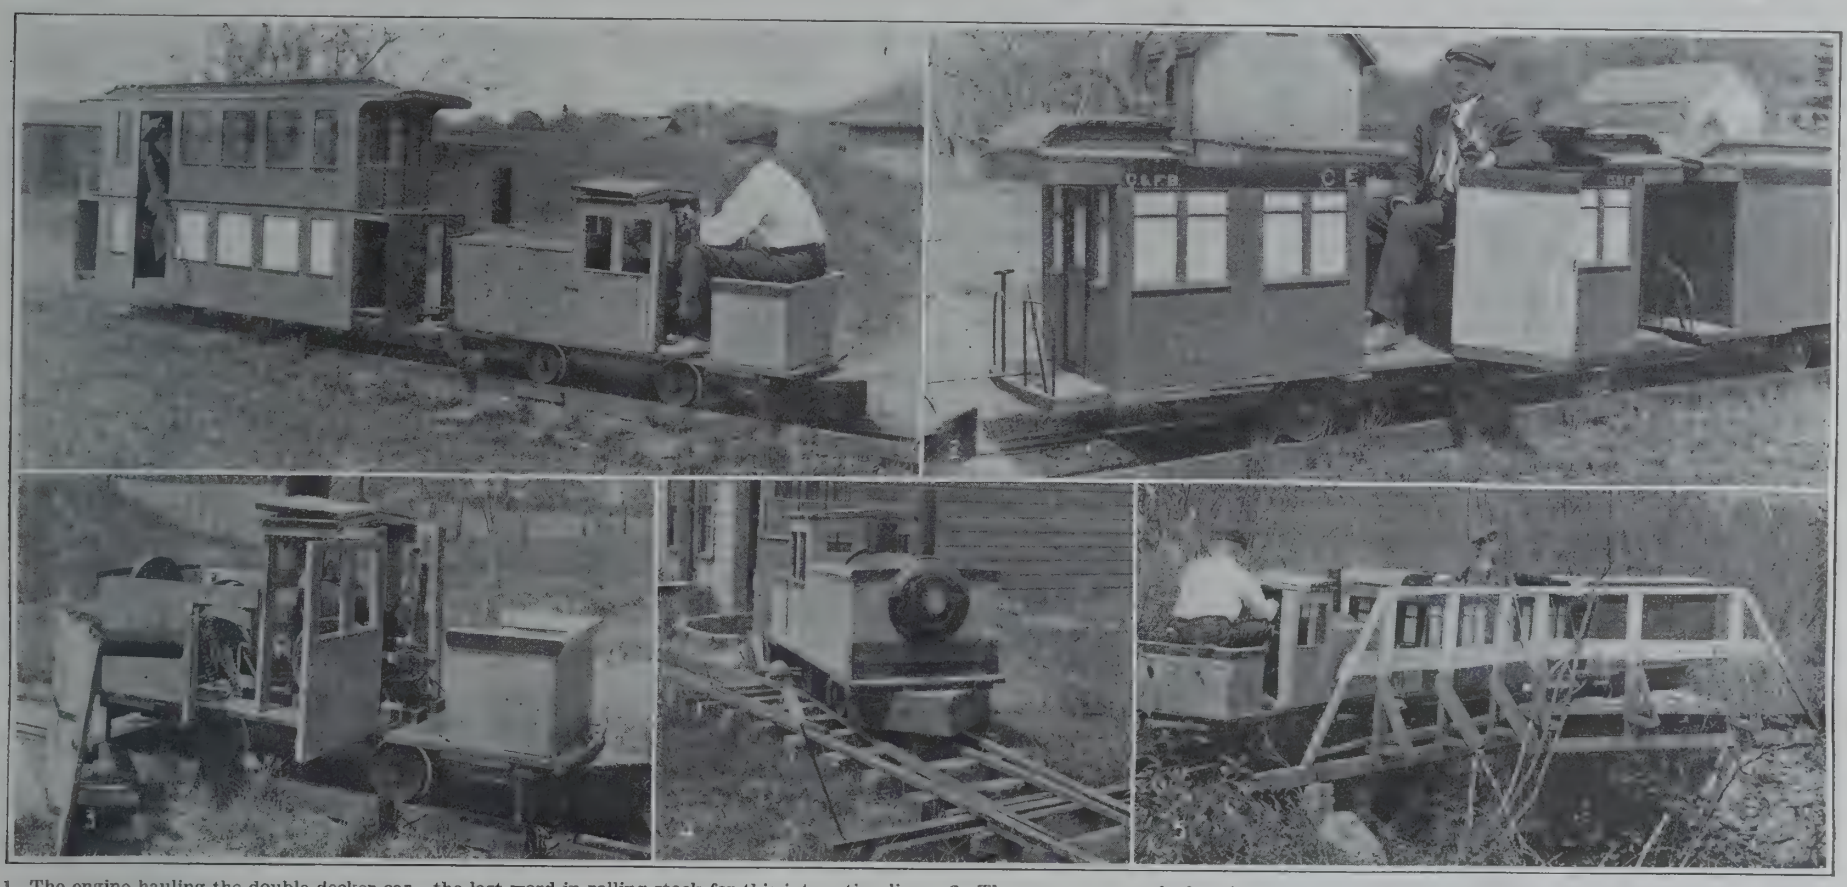
THE WEEKLY JOURNAL OF PRACTICAL INFORMATION

VOLUME CXXIII. NUMBER 3 ] NEW YORK, JULY 17, 1920 [ 15 CENTS A COPY $5.00 A YEAR



1. The engine hauling the double-decker car—the last word in rolling stock for this interesting line. 2. The passenger cars look quite like the real thing, but their interior arrangements are slightly different. 3. Showing some of the details of the locomotive, with its gasoline engine. 4. A one-car passenger train leaving the roundhouse. 5. A bit of rural scenery where the road crosses the brook.

**Toy railroad of much utility built as a hobby from old lumber by a New York farmer**

## A Tiny Railroad, at Once a Toy and a Tool

WHEN the city man sets himself up on the farm, either upon his retirement from active business or in connection with the establishment of a summer residence, he seldom confines his attention to mere farming. Something in the way of a side-line is bound to catch his fancy and lead him on until the farm itself has become more or less a side-line, while the original passing notion is the serious business of the estate.

Few gentlemen farmers, however, can boast a hobby as unusual as that of Mr. W. C. Gage, who a couple of years ago gave up his activities as a New York broker to enjoy the peace and quiet of his farm up the state. Mr. Gage found that the facilities for local communications between the several parts of his farm were not of the best. He also found that he had an abandoned chicken house about 250 feet long, which was thoroughly useless as a chicken house and in which the lumber was beginning to deteriorate. So he proceeded to kill three birds with one stone by using this lumber to renew the lines of transportation, and to have a bully lot of fun in the bargain.

The pictures show the miniature railroad—we cannot properly call it a play railroad because, while Mr. Gage plays with it a lot, it also does a lot of the serious business of the farm—at any rate, the pictures show what Mr. Gage made from his old hen house. He laid wooden rails to all sections of the farm, built a few tiny cars of various types, and set to work on an engine to pull these. It will be seen that while the engineers and the passengers occupy rather unconventional accommodations in the various units of rolling stock which make up Mr. Gage's equipment, these units are all got up, externally, to carry out the illusion of regular railroad stuff.

The locomotive is no dummy at all; it mounts a four-horse-power gasoline engine, which is ample to pull the cars at a decent speed over the rails which are supplied for the purpose. It is built for service rather than style, so the engineer has to imitate the oarsman and ride with his back toward the place to which he is going; but that is no great drawback. The passenger cars are capable of carrying two passengers each; and one double-decker car, with glass windows and all the other trimmings, is altogether de luxe.

Mr. Gage's road possesses, in addition to the passenger-carrying equipment, box cars and flat cars of ample size and in ample numbers to do all the hauling business of the farm, and to do it efficiently—in fact, he insists that his hobby justifies its existence in this manner. During the week he travels about the farm gathering up the produce and distributing manure and other necessaries; then on Sundays and holidays he totes the admiring visitors about in his miniature trains. Bridges, cross-ties, signals, and everything else that can add to the railroading atmosphere are to be found here—and all of wood, all home-made by Mr. Gage right on the spot.

## Stained Glass Once More in Vogue

ALL the valuable stained glass windows were removed from the large churches in Paris in order to protect them against air raids and destruction by long range gunfire, during the war. The windows were stored in safe places and remained unharmed. They are now to be carefully retouched and renovated and then to be reinserted. These windows total approximately 470,000 square yards of stained glass, and their renovating will take a long time and will be of considerable expense.

A wide and remunerative scope of work has thus been opened to the Paris Association of Glass Stainers, some members of which are noted artists. Although this association and some other guilds of glass stainers work entirely in a mediaeval craft it would be wrong to conclude that their methods are behind the times. Fifty years ago the old secret of staining glass, which was lost with the decline of art in the 17th and 18th centuries, was rediscovered and, with the aid of chemistry, has made remarkable progress. This is shown by the fact that today the glass stainer disposes of over 5,000 different pigments, while in the 12th century, the golden age of glass staining, only twelve colors were known.—By *J. E. Boos.*

## For Spark Plug Electrodes

THE use of cements for sealing electrodes into spark plug porcelain has been found to be attended by serious difficulties in high temperature engines such as airplanes. Among these are: promotion of oxidation and destruction of the electrode wires by reactions taking place in the cement and between the cement and electrode wires; breaking of spark plug porcelains caused by difference in coefficients of thermal expansion of electrode wires and porcelain, and cracking of cement, with consequent gas leakage, due to the same cause. A cement composed of silicate of soda and raw kaolin has been found to give little trouble from chemical action. In order to avoid the difficulties attending the use of any form of cement, the use of a mechanical seal at the top of the porcelain has been tried with promising results. Those interested are referred to Technologic Paper No. 155 of the Bureau of Standards, "Cements for Spark Plug Electrodes," which is now ready for distribution and any one interested may obtain a copy by sending a request to the Bureau.

## The All-Metal Monoplane

THE recent 1,400-mile non-stop flight on an all-metal passenger-carrying monoplane is notable, both because of the distance covered and because of the special design and materials of the machine. The all-metal monoplane has particular interest for this journal, for the reason that as far back as 1910, the SCIENTIFIC AMERICAN published its own design for a racing monoplane, built entirely of high-grade alloy steel. The article was inspired by a study of the highest types of airplanes of that period, as represented in the celebrated meet, ten years ago, at Belmont Park, all of which, including even the fast Bleriot monoplane, were so encumbered with wire and wood struts and ties, to say nothing of the elaborate landing gear, as to present a large and, as it seemed to us, unnecessary amount of head resistance. It was our conviction that by the use of steel construction throughout and by the adoption of the monoplane type, it would be possible to give the wings sufficient thickness for the insertion within them of transverse beams of sufficient depth to provide the necessary bending strength, thereby getting rid of all exterior trussing. The body of the machine was of oval cross section and streamlined, and in place of linen the wings and the body were covered with very light corrugated steel plating. The landing gear folded against the under side of the body when the machine was in flight, and automatic stability was secured by means of a compressed air cylinder, whose movements, controlled by a gyroscope, actuated the ailerons.

The suggestion was ahead of its day, but with the coming of the wonderful aluminum alloys that are now available, the design took practical shape, and toward the close of the war the Germans built some very successful monoplanes, which dispensed entirely with wood and linen fabric, depended for their wing strength on internal trussing, and were covered as to wings and body with thin corrugated aluminum plating. We believed then and we are still of the opinion that the fastest machines of the future will be of the monoplane type.

## The Scientific Basis of Sport

CONSTANTLY we refer, in speech and in writing, to the human mechanism and the human machine, or use some metaphor that draws analogy between the human body and the structure of metal, stone and wood. Often too we reverse the figure and speak of a machine that seems almost to be endowed with human intelligence. But when our little flight of rhetoric has served its purpose, we lapse back into a state of mind where we recognize that of course a man and a machine are two fundamentally different things. It were trivial to catalog the many distinguishing points that separate the human from the mechanical; but we may single out one of these points for purposes of adorning a tale.

We never design or install a machine of any consequence without considering carefully what it will do. Always there are understood to be certain things that a machine will do, and certain other things differing only in degree but which it will not do. It will travel 60 miles per hour but not 80. It will haul a load of 50 tons but not one of 75. It will turn out 10 tons of concrete mix an hour but not 11.

We go further than might necessarily appear on the surface of these remarks. We assume that under like operating conditions the machine will give like performances. We assume that if it will make 60 miles an hour today it will do the same tomorrow and next week and throughout its useful life. This may not seem to be an assumption—it may appear founded upon the immutable laws of cause and effect. But if we will compare the machine with the man on this basis of constancy of performance, we will see that we make an assumption, and a very material one, when we ask the machine to do a thing today merely because it did that thing yesterday.

As we write, Mr. Hagen has just lost out in his effort to annex the British golf championship. Four times he propelled the little white sphere over the landscape at Deal. Once he had to hit the ball 84 times to produce the desired results; again he required 82 strokes; twice he got around in 78—all over the same course. Duncan, the ultimate winner, on the second day negotiated the 36 holes in 143 strokes as against 160 which he used up the day before. No record of the occasions on which Hagen has turned in a better performance or Duncan a worse one is needed to establish the fact that what a man does today in golf, tomorrow he may repeat and he may not.

Again, as we write, Mr. Tilden has just taken unto himself the championship of the world in the game to which he devotes his attention—tennis. In doing this he had to defeat Mr. Parke, who had the day before beaten Mr. Johnston, who last year beat Mr. Tilden decisively for the American title. In the same tourney, Williams and Garland, on all performances of the past by far the weaker of the American teams, took the doubles title right out of the grasp of no less formidable a combination than Tilden and Johnston. On the basis of previous performances who would have dared predict all this? Who would be rash enough to assert that if the tourney were played over, the same results would be attained?

A couple of weeks ago the Brooklyn baseball club went to Boston for six games and lost five of these. They have just returned from a second invasion of the hub, during which they played and won four games. And because this morning's papers narrate how the club that represents New York in the other league scored 14 runs in a single inning against Washington does it follow that they will win the next time they face the same pitcher?

We have paraded these examples of human mutability from the field of sports because it is in the field of sports that we shall draw our moral. The fact remains, we can never predict that because a human being has done a thing he will do it again when he tries it again. The causes which contribute to a good or an average or a poor showing in any intensive human effort are so very many and so very complex that they defy analysis and prediction alike.

After all, isn't it better thus? Where would the zest and the competition in sport be if we could say "Well, A beat B last year, so B doesn't stand a chance against him now." There would not be any competition at all, except between "maidens," if we may borrow a term from the sport of kings. After a newcomer in any field of sport had met all the leading players, his place would be immutably fixed, and he could experience the real thrill of uncertainty, the real zest of competition where the result is at issue, only against other newcomers. So from the point of view of real sport, it is mighty fortunate that the human mechanism does not "run to form" like a true machine, and that constancy of performance is something to which no human can do more than achieve a rough approximation.

## The Folly of a Divided Fleet

WHATEVER political expediency there may have been in dividing our fleet between the Atlantic and the Pacific, from the standpoint of military efficiency, national defense, and economy, it was one of the most faulty moves ever made in the administration of the United States Navy.

A strong statement—but having behind it the Navy's greatest strategical authority; for in 1912, Admiral Mahan said: "To divide the battle fleet would be the most entirely suicidal act that could be contemplated."

The results of dividing the fleet are bad at best, and positively disastrous at the worst. In the first place, a divided fleet practically doubles the requirements for flagships, supply vessels, tugs, targets, flag officers and staffs, shore bases—in fact for everything which in business would be known as overhead expense. By combining the two fleets and reducing the ships and staffs now duplicated we should save several hundred officers, several thousand men, reduce Government expenditures by several million dollars and greatly increase the efficiency of the Navy.

Again, divided fleets develop doctrines and ideas independently of each other, according to the admiral in command. When the fleets come together for combined exercises, they do not readily amalgamate, for their training has differed. You could not throw the Princeton and Yale football teams together overnight and expect them to play an efficient championship game with Harvard the next day. Team work in a great fleet can be obtained only as a result of long practise. Neither half of a divided fleet is as big as the combined fleet would be in war. Therefore, during peace the Commander-in-Chief is not obtaining the training he should have in handling and maneuvering the large number of vessels that would be under him in war time. An occasional assembling of the two fleets under one command would never provide the requisite training. It should be continuous throughout the command of the Commander-in-Chief.

When the fleet was divided several fallacious arguments were offered in support of the move; but the claim that competition is stimulated by having two separate fleets five or six thousand miles apart by sea is ridiculous. The two fleets are so separated, mail communication so slow, weather conditions so different in the two oceans, that real competition does not exist. Keenest competition is secured when a large force of vessels is assembled, all in sight and in touch with one another. Greater effort is necessary to win the pennant for engine efficiency, gunnery, or what-not in a fleet of one hundred ships than in one of fifty.

The strongest argument of all, the one which Admiral Mahan had in mind when he called the policy of division "suicidal" is that a divided fleet gives an enemy an opportunity to destroy the two fleets in detail. A Japanese fleet, by interposing, might catch one-half of the fleet at a disadvantage; similarly a European nation, by placing a fleet in the West Indies, might accomplish the same end.

The teaching of history, the warning of our greatest naval strategist and the present crying need for economy, unite in demanding that our fleet, no matter where it may be based, shall be reunited into one powerful unit.

Consider the score of economy. Many of our naval ships still burn coal, and there is no coal on the Pacific—it has to be taken there at a huge expense by colliers. Even as regards oil fuel, it should be remembered that while the cost is about the same on each coast, there is a greater supply on the Atlantic with more tanks and better facilities for handling it—hence, fewer tank vessels will be needed and much money saved. The argument on the score of general supplies is even stronger, for nearly all supplies are manufactured on the Atlantic side.

Labor, the greatest element of cost today, is very limited in the Pacific and is more expensive. The same thing is true of steel, all of which comes from the East. Of the greatest importance, too, is the question of personnel, most of which lives on this side of the continent. We have here a more fertile area for recruiting and the nation is put to very great expense in transporting the personnel to and from the Pacific when enlistments and changes have to be made. Finally, in the important question of morale, we must remember that sailormen are as human, perhaps a little more so than the rest of us. They all like to get home occasionally, and as the homes of the majority of the men are on the Atlantic side, it follows that if half the fleet is based upon the other coast there will be a falling off of enlistments and an inevitable discontent engendered.

## Naval and Military

**The Capsize of Eagle Boat No. 25.**—The Eagle boats have never been popular either inside or outside of the Navy. We confess that to our eye they have always looked unstable, and this defect was emphasized during a severe thunder storm on June 11th, when Eagle Boat No. 25 capsized with a loss of nine of the crew. A heavy wind struck the boat during a severe electrical storm; but although she turned turtle, other craft in her vicinity came through the test in safety. The boat was two hundred feet in length, twenty-five feet six inches in beam, and had a displacement of about six hundred tons.

**Our Future Army Strength.**—The official figures for the strength of the Army of the Reorganization Act of 1920 show an authorized strength of 298,882 commanding officers, warrant officers and enlisted men, of which the Infantry will have 38.2 per cent; the Field Artillery, 13 per cent; the Coast Artillery, 10.5 per cent; the Cavalry, 7 per cent; the Air Service, 5.9 per cent; the Corps of Engineers, 4.2 per cent; and the Signal Corps, 1.8 per cent. The annual appropriations for 1914 for the Army was $94,266,145, which is slightly less than one-quarter of the Army appropriations for the fiscal year 1921.

**Expenditure of Ammunition in Flanders.**—The final report of Sir Douglas Haig includes some amazing figures of ammunition expenditure in Flanders. In the opening attack, in 1917, the total expenditure on July 31st exceeded 23,000 tons; and on the two days, September 20 and 21, 42,000 tons were expended. From the commencement of the British offensive in 1918 to the conclusion of the Armistice 700,000 tons of artillery ammunition were expended by the British Army on the Western front, while in the three days of crucial battle on the 27th, 28th and 29th of September, nearly 65,000 tons of ammunition were fired by their artillery.

**The Latest Rigid Airship.**—In the latest rigid airship, R-80, as developed by the Vickers people, particular attention was given to the elimination of unnecessary head resistance and the cutting down of weight, and the builders have produced in R-80 a ship of only 1,250,000 cubic feet capacity, whose performance in speed and endurance is equal to that of R-33 and R-34, which have a capacity of 2,000,000 cubic feet. The over-all length of R-80 is 530, its diameter is 70 feet, and its height, 85 feet. The total gross lift is 38.5 tons at sea level, and the disposable lift is 17.5 tons. At full power, the estimated speed is over 60 miles per hour, and the cruising radius at this speed is 4,000 miles, and 6,500 miles at fifty miles per hour.

**The Object of Lofty Flying.**—The Air Service has issued a statement explaining the object of Major Schroeder's recent flights at altitudes in which he made a world record. It says that there was long and careful planning and much experimental work was done before the flights were attempted. Future wars will be fought largely in the air, and, because of the development of anti-aircraft guns, much of the airplane work will be done at altitudes of 20,000 feet and over. For flight at these altitudes, the aviator must be provided with devices which will enable both him and his machine to function properly, and it is these facts which have caused the Air Service Division of the military service to carry on this highly scientific and very successful work.

**The Seventy-Five Mile Gun.**—We stated, in our issue of April 27, 1918, that the Germans were probably using one of their 15-inch naval guns with a subcaliber tube inserted to obtain the necessary length for the great range of seventy-five miles. It now appears that they did use several worn-out, 45-caliber, 15-inch naval guns. They screwed on to the muzzle of this great gun an additional outer tube forty-five feet in length, and then inserted a tube one hundred feet in length, which was bored and rifled to a bore of 8.2 inches. To the gun as thus assembled they added a smooth-bored twenty-foot section, the total length being 120 feet. This great length was adopted in order to keep down the powder pressure and the erosion. The guns, because of the inequalities in the powder were erratic, and it is believed that after fifty rounds they became so worn out as to be unusable.

## Science

**Making Streets Safe for School Children.**—A commendable campaign among school children is being conducted by the Safety Bureau of the Philadelphia Rapid Transit Company. More than 185,000 school children in that city have listened to stories and talks on "Safety First," and three-quarters of a million pieces of illustrated printed matter on the same subject have been distributed in the schools. A striking feature of this campaign is an organization of 300 boys who daily patrol crossings in the dangerously located school neighborhoods.

**A Naturalist in an Airplane.**—Dr. Chalmers Mitchell, who took part in the recent attempt to fly from Cairo to the Cape, has sent to the *Times* (London) a detailed account of his observations, which serves to illustrate how much valuable work in physical geography and kindred subjects may be carried out by a suitably qualified airman. His bird's-eye view of the Nile basin is a notable contribution to our knowledge of the physiography of that region and of the geological processes which have occurred there. He also furnishes interesting information concerning the larger animals observed along his route.

**More Light on Botulinus Poisoning.**—According to the U. S. Bureau of Chemistry the recent sensational cases of poisoning from ripe olives have occurred almost exclusively in connection with olives put up in glass. A plausible explanation is offered by the Bureau. It appears that the trouble is due to defects in the methods of pickling, packing and processing the olives. In most establishments the product when packed in glass is sterilized at about the temperature of boiling water, and this temperature is too low to ensure the destruction in every instance of the *Bacillus botulinus* and the toxin it produces. The trouble, the Bureau says, is not inherent in the glass container, if sound olives be used and the packages are properly sealed and sterilized. Unfortunately some of the packers in their anxiety not to break the glass containers do not always process the olives at a sufficiently high temperature. The poison would develop just the same in tin under the same circumstances, but as there is no danger of breakage in tin there is usually no hesitation on the part of the packer to apply sufficient heat. The Bureau is urging producers and dealers to make a thorough inspection of all ripe olives in glass and to destroy any that show the slightest sign of decomposition. It is also recommended that all olives, whether in tin or glass, which may have been processed at too low a temperature be sent back to the packers for reprocessing.

**International Meteorological Conference.**—The report of the International Meteorological Conference which met in Paris last October, at the invitation of the French Government, has just been published. In view of the far-reaching changes that have recently taken place in the scope and methods of meteorological work—due especially to the new requirements of commercial aeronautics—this meeting was timely, and most of the national weather services of the world were represented by delegates. The General Powers were not invited to participate; and the United States of America, which possesses the most imposing meteorological bureau in the world, was not represented, because Congress failed to make the modest appropriation recommended by the President to provide for the expenses of two delegates. The conference decided to perpetuate, with some slight modifications, the international organization of meteorology that existed before the war. Sir Napier Shaw remains president of the International Committee. Much important work was accomplished by the conference, looking to a material enlargement in the scope of weather reports and their dissemination, especially by wireless, for the benefit of aeronauts. In lieu of the old commission which bore the misleading name of International Commission on Scientific Aeronautics there were organized two new commissions; one on the applications of meteorology to aerial navigation, and one on the exploration of the upper atmosphere. There are also international commissions on agricultural meteorology, weather telegraphy, marine meteorology, solar radiation, the *Réseau mondial*, terrestrial magnetism and atmospheric electricity, and polar investigations.

## Automobile

**Keep Clips Tight.**—Spring clips should be inspected at least once a week and tightened as much as possible. If the clips become loose, the spring will break between the clips. If there is undue stretching of the clips, the difficulty might be overcome by having new clips made of better material, as it is always cheaper to replace clips which are too light than to have broken springs as a result. The bearing place upon which the spring rests on the axle should absolutely conform to the curvature of the spring at that point, as sufficient bearing surface is just as important as tight spring clips.

**Why Horses Are Retained on Farms.**—When discussing the motorization of the farm, agriculturists are always ready to state that even though most of the work of the farm will be done in the future by motor devices, the horses will still be found necessary. Attention has been called to the fact that street car railroads were electrified and for a long time maintained large stables of horses. Electric roads have no horses today. Big business in the large cities motorized and for long periods continued to maintain stables of horses because of some lack of confidence in the motor equipment to meet an emergency that never came. Big business interests are now gradually giving up their horses. Farmers will motorize and continue to keep their horses until such time as their confidence is thoroughly established in the motor equipment of the farm motor truck, tractor, etc., when they will quickly give up the horses.

**Automotive Industry Magnitude.**—That 1920 will be the greatest producing year thus far in the history of the automotive industry can be readily foreseen, with the great demand for motor vehicles in this and other countries. Production in America has reached such a point that the National Automobile Chamber of Commerce announces that this year's business will rank second only to steel. The 1919 production totaled $1,807,594,580 and if bodies and accessories were included, this figure would exceed $2,000,000,000. Exports of automobiles and parts, including tires and engines, for the government's fiscal year ending June 30, 1919, surpassed all previous records by aggregating $185,000,000. The former high record was in 1916, when $140,000,000 business was done with foreign nations. Of the total amount of 1919 exports, $35,000,000 worth was commercial cars, $75,000,000 worth was passenger cars, $41,000,000 parts of automobiles and nearly $30,000,000 worth was tires, while about $5,000,000 worth was automobile engines.

**Taking Down the Motor.**—In order to look over the parts of an engine and to restore the worn or defective components it is necessary to take the engine entirely apart as it is only when the power plant is thoroughly dismantled that the parts can be inspected or measured to determine defects or wear. If one is not familiar with the engine to be inspected, even though the work is done by a repairman of experience, it will be found of value to take certain precautions when dismantling the engine in order to insure that all parts will be replaced in the same position they occupied before removal. There are a number of ways of identifying the parts, one of the simplest and surest being to mark them with steel numbers or letters or with a series of center punch marks in order to retain the proper relation when reassembling. This is of special importance in connection with dismantling multiple cylinder engines as it is vital that pistons, piston rings, connecting rods, valves, and other cylinder parts be always replaced in the same cylinder from which they were removed, because it is uncommon to find equal depreciation in all cylinders. Some repairmen use small shipping tags to identify the pieces. This can be criticised because the tags may become detached and lost and the identity of the piece mistaken. All parts should be thoroughly cleaned with gasoline or in the potash kettle as removed, and wiped clean and dry. This is necessary to show wear which will be evidenced by easily identified indications in cases where the machine has been used for a time, but in others, the deterioration can only be detected by delicate measuring instruments.

# A Chemical Loafer, and How It Was Put to Work

## Argon, the Laziest of All the Elements, Plays a Big Rôle in the Latest Incandescent Lamps

By E. W. Davidson

ONE of the most useless of the constituent elements of the air we breathe was turned to a highly valuable use for mankind when argon gas was first injected into incandescent lamp bulbs. By filling lamps with this gas which is among the laziest of all gases, and by observing certain precautions, the efficiency of the lamp thus made was greatly increased. Furthermore, argon gas has helped the larger sizes of incandescents up to the huge 1,500 watt lamp to displace arc lamps for street lighting purposes.

Sir William Ramsey first discovered argon in 1894 which he found to constitute about one per cent of the atmosphere. By this discovery he filled out one of the blanks in the chemical periodic system. Previously it had been noted that nitrogen extracted from the atmosphere was heavier than nitrogen produced by chemical process. The search for an explanation of this led to the discovery of argon. But he found absolutely no practical use for the new gas. For 25 years this valuable element was permitted to continue in its happy state of desuetude.

Nobody used argon until Dr. Irving Langmuir in the Research Laboratory of the General Electric Company at Schenectady discovered the increased efficiency to be gained in incandescent lamps by filling them with inert gas instead of merely making them vacuous. He used both nitrogen and argon.

Nitrogen was promptly put to use in lamps because it is comparatively easy to extract so prevalent an element from air, but nobody used any argon on a large scale until about 1914 when an air products company constructed machinery, which by fractional distillation from liquid air, produced it in considerable quantities mixed in equal parts with oxygen and nitrogen. This is the form in which it is marketed today. At lamp factories the oxygen is thoroughly removed by passing the mixed gases through a tubular furnace nearly filled with copper filings at red heat and about 90 per cent of the nitrogen is extracted in another furnace. Then the argon, about 90 per cent pure, is injected into lamp bulbs.

The very inertness which once stamped argon as absolutely useless has proved to be its valuable quality. The facts that it is relatively stubborn in its refusal to serve as a conductor of heat and that its density discourages the evaporation of tungsten filaments even at tremendous heat have therefore made it possible to increase the temperature of lamp filaments with a consequent increase in lamp efficiency beyond the point which was the previous maximum. So a greater candlepower is possible without undue deterioration of the filament; or keeping candlepower fixed, the life of the bulb is prolonged.

The air is exhausted from the lamps when the turn-table carries them through the oven. They come out at the left, are cooled by air-blast, and as they come to the position beneath the operator's left hand the argon is injected from below.

**Filling lamp bulbs with the purified argon**

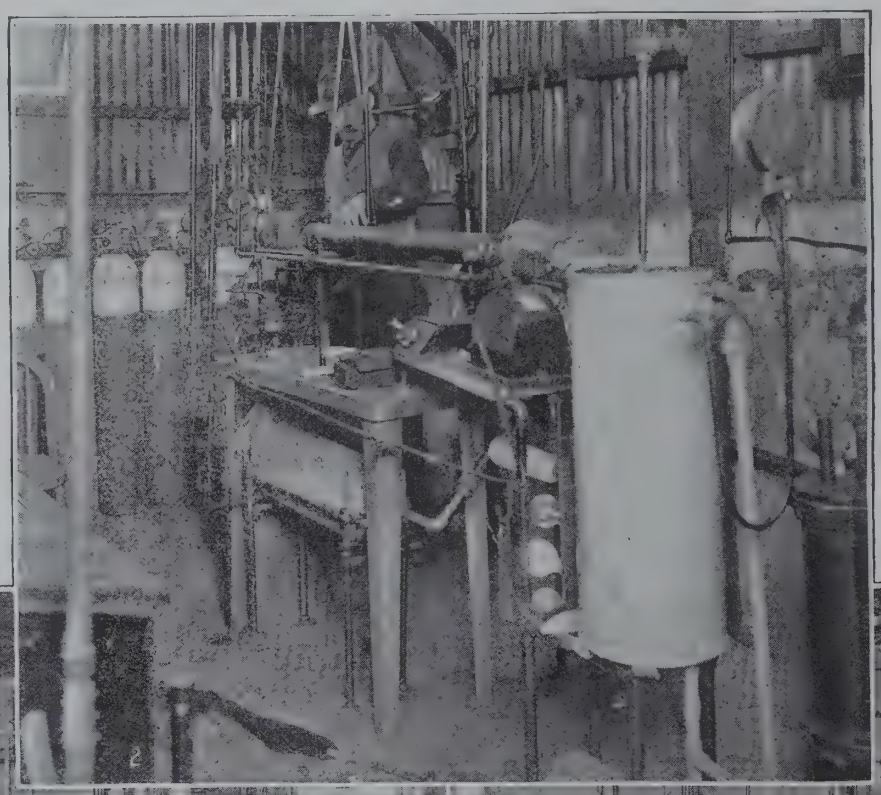
Although it has not been economically advantageous to use argon in the lowest current lamps, its use renders the higher current lamps more brilliant and efficient. Large argon-filled lamps equal in efficiency the magnetite arc, so as to serve for any sort of street lighting except to produce the brilliant glare needed for "white ways." Argon-filled incandescents, which can be mounted in varying sizes on a single circuit to meet varying needs as arcs cannot be, and whose glow never flickers as does the glare of arcs, have established their supremacy for general outdoor lighting as well as for other medium and high-power illumination needs.

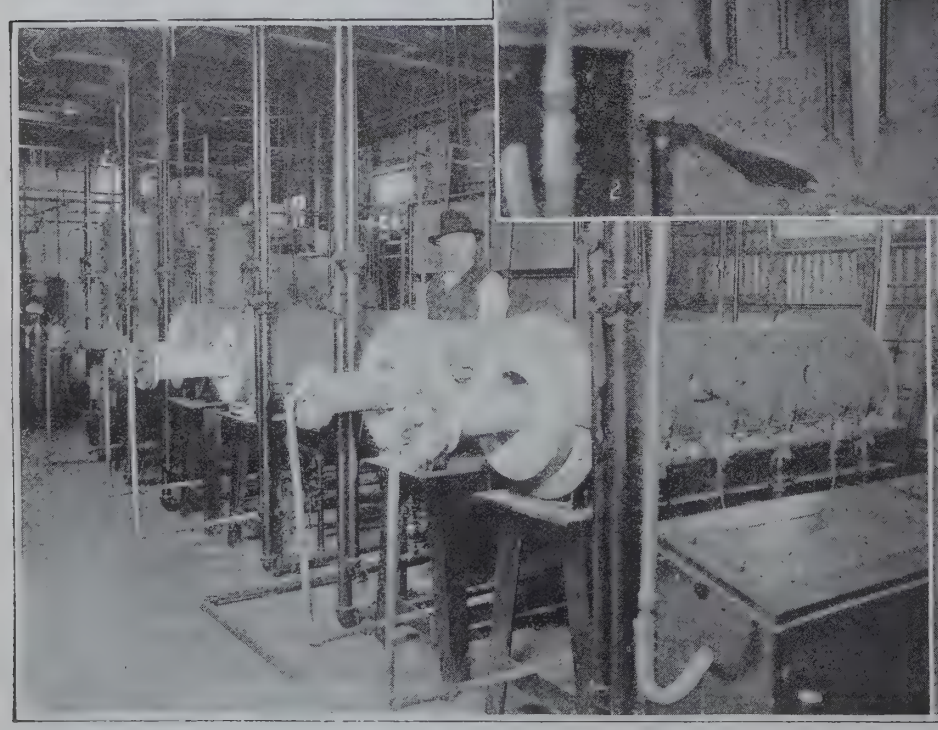
### Rail and Street Car Indicator

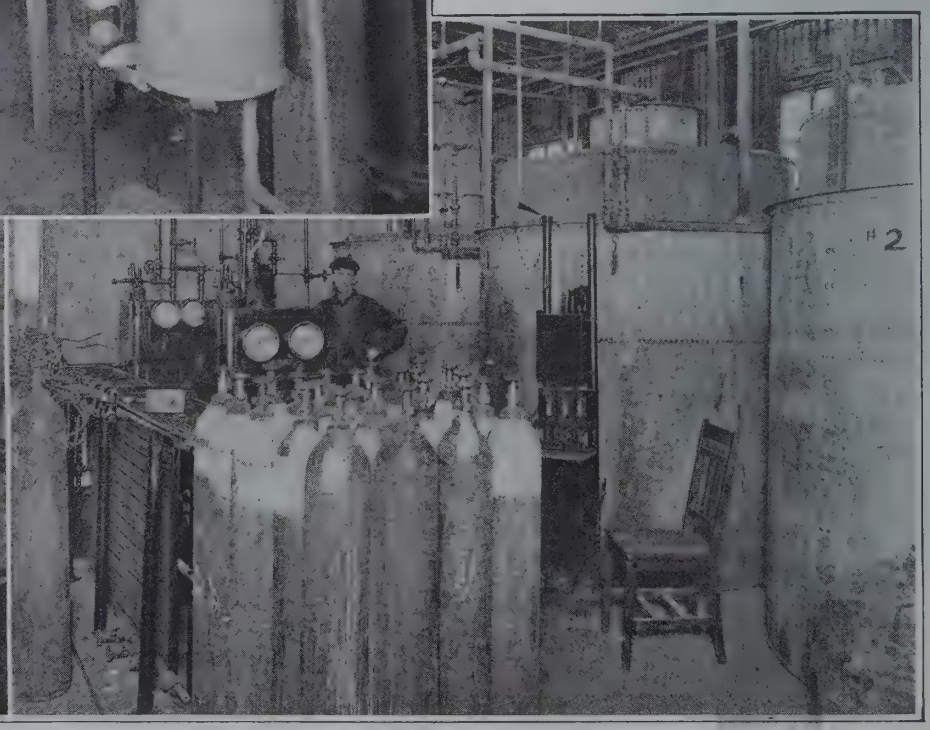
THE London Metropolitan Railroad has arranged to put into operation on its system an electrical device whereby the names of stations are indicated in the passenger cars. The system is operated by illuminating sections of the ceilings of each compartment, arranged in panels, each of which in turn becomes prominently lighted up as the journey proceeds. At the commencement of the journey the next station becomes so indicated; when that point has been left, the section or panel applying to it becomes dull, but the next becomes illuminated. Before starting a journey the motorman actuates a series of switches, and the rest of the action is automatic, the mechanism being operated by a small striker on the track between the stations. In addition to the names of the stations, it is intended to show a map of a square mile of streets around each spot, giving shopping centers and amusement places.

This indicator is to be put into operation on the Great Northern tube.

The concern controling the device claims that as passengers will thus easily become acquainted with their whereabouts, time should be saved and congestion relieved.

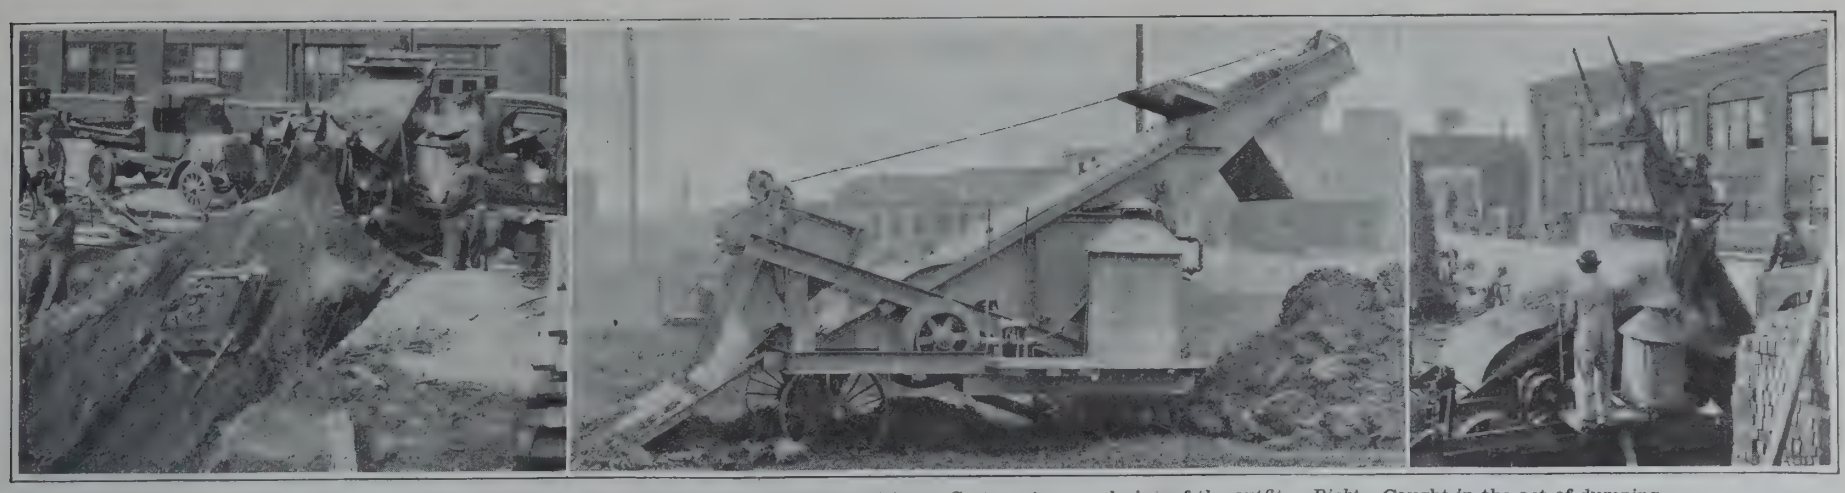






1. The calcium carbide furnaces in which the argon is purified of nitrogen at a temperature of 900° Centigrade, and brought up to 80 per cent pure. 2. The first step; the commercial argon received in the cylinders is burned in a hydrogen flame to free it of 30 per cent of oxygen, after which it goes to the furnaces shown in the first photograph. 3. The finally purified argon is pumped through big meters and into the cylinders, from which it is fed into the lamps.

**Removing oxygen and nitrogen from commercial argon to make it fit for use in filling incandescent lamp bulbs**



*Left :* Hauling the drag full of excavated material up to the dumping position. *Center :* A general view of the outfit. *Right :* Caught in the act of dumping

**The drag-line excavator-loader that delivers the material to the truck in the very bucket that digs it**

## Digging and Loading in One Motion

**By B. F. Mundorff**

A NEW excavator-loader is especially designed for excavating work, for the removal of materials from one location to another and for general work where flexibility of operation is not limited so closely as in the case of the steam shovel. It likewise eliminates the pickax and shovel worker entirely.

The machine is in reality a portable dragline, filling the gap between the steam shovel and the antiquated and expensive gang of hand shovelers. Because of the principle on which it operates, portability is a feature "built in" this excavator and loader. Only two men are necessary to the operation of the machine; one at the operating levers and one at the loading point. To a point anywhere within 50 to 200 feet from the machine is stretched a chain, at right angles to the line of digging; upon this chain are two sheaves hooked to the chain. Either sheave may be unhooked and relocated in an instant. One heavy cable passes from the hoist drum on the machine, then to the digging skip, then through both sheaves, back to the retrieving hoist drum on the machine.

The operator of the machine manipulates but two levers and a foot brake. As he places power on the digging line the other man manipulates the handles on the skip, so as to fill it with the material to be dug or removed. The skip has a capacity of 15 cubic feet per trip. As soon as the skip is filled the man releases the handles and allows the skip to ride to the excavator. As the skip strikes the apron at the machine it unlocks the catch arm then carries the skip up over the machine and on to a slanting chute located on the front of the machine from where the material in the skip discharges into the waiting wagon, truck or railroad car. The skip is then quickly retrieved to the starting point and the operation repeated.

**Shoveling the coal on the barge for delivery ashore**

## Pedigreed Chicks from Incubators

WHEN eggs are hatched in incubators, the difficulties incidental to pedigree work are such that many poultrykeepers do not attempt it, simply using eggs from selected hens and letting it go at that. Others hatch special pedigree eggs under hens. Mosquito netting bags for incubators, into which the marked eggs are placed on the 18th day of incubation, each sack being indexed, are successful, but somehow do not "catch on" with poultry breeders. The new cornpopper plan will be much more popular with the average breeder. It is so simple that any poultrykeeper can use it.

Two-quart wire cornpopper baskets, the common kind purchasable at any hardware or general store, are used, one basket for the eggs of a particular hen. Attached to the basket is a tag on which the hen's number is entered. During the hatching time, in this manner, the chicks of one hen, or the chicks of several, may be kept separate. Whether the pedigree work is simple or elaborate, the cornpopper plan is efficient. The breeder must bear in mind that when cornpopper wire baskets are used chicks have less room to hatch in than when the whole floor of the incubator is free to them. If the hatching percentage is heavy, and many of the eggs are pedigreed, there can easily be overcrowding. For this reason the poultry keeper should watch the operation, and if an emergency arises be prepared to transfer some of the eggs for hatching to a second incubator, so that there will be room for all. The object can be attained by loading incubators under capacity.—By *J. T. Bartlett.*

**The screen that separates the coal from water and non-combustible solids**

## Mining Coal with a Dredge

**By George Gaulois**

IN many parts of the anthracite and bituminous fields of the East there are to be found locations where the mad rush of previous generations to skim the cream from Nature's offerings, regardless of what happened to the skimmilk, has resulted in leaving in the river bottoms large accumulations of coal which the miners of a generation ago felt that they could not afford to transport to market in the presence of better grades and more convenient sizes. Today, in the search for economies, we are beginning to bring this coal to the surface and avail ourselves of it. In addition, there are a few places where there appear to be deposits of coal in their original positions at the bottoms of water courses, and these frequently can be mined by the same methods utilized to get at the submarine dump-heaps of former days.

Sometimes the work is done from shore, sometimes from barges moored out in the stream. We illustrate herewith a process of dredging, followed by screening of the material brought up from the river bottom, which is resulting in the recovery of a lot of good coal from the Susquehanna River, near Danville, Pa. The coal here is of fair size and good quality, and comes from the water in the shape of smooth rounded lumps. There is of course a good deal of non-combustible solid matter with the coal, but this can be said of mine coal, and its removal from damp, dustless river coal is if anything more easily effected than in the case of coal brought up from below ground. One of our illustrations shows the apparatus with the aid of which this is accomplished and the coal separated from the water at the same time, while the other gives ocular evidence that this scheme for coal recovery is on a very respectable scale.

## A New Form of Vibration Galvanometer

VIBRATION galvanometers are very useful in zero measurements, but have not been much used in industrial laboratories on account of their being sensitive to external vibrations and requiring delicate adjustments. A new instrument developed by the United States Bureau of Standards, which has a sensitivity higher than other forms of the moving-iron type, but less than that of the most sensitive forms of the moving-coil type, has the advantages of sturdiness, quick responsiveness, and freedom from the effects of external vibration. It consists essentially of a fine steel wire mounted on one pole of a permanent magnet, and so arranged that the free end of the wire may vibrate between the poles of an electromagnet through which the current to be detected passes. The paper describing this instrument, Scientific Paper No. 370 of the Bureau of Standards, is now ready for distribution and any one interested may obtain a copy by addressing a request to the Bureau.

# Turning the Wheels of a Century Hence—III

## What the United States Must Do to Forestall the Day When Fuel Goes Beyond the Common Reach

By C. H. Claudy

THE first reason, of course, why we have not developed every bit of our available water power, is the economic factor that all water power is not sufficiently near a market to make its development commercially possible. That is a condition which time will remedy as the demand becomes more acute; a market will be created by industries willing to move to or near the power site. Second is the fact that water is an asset of the nation, not of individuals, and that in a laudable endeavor to conserve the nation's asset for the nation, the nation's legislators have often gone too far and put such heavy restrictions upon the construction of water powers as to scare away capital and make it afraid to invest. Such a restriction is found in the requirement that a Federal license be revokable by the power of one man. No one man, no matter how wise, has vision enough adequately to consider all points in so complicated a question as this, and capital rightly believes that it should not risk its life against the decision of a single individual.

Third in the limiting factors is the conflict of interests between the power makers, the power users and the users of water as a means of transportation. No navigable river should be closed to navigation by the construction of a power dam. So much is self-evident. But navigation interests go farther than that, and frequently object strenuously to a power dam, even if provided with adequate locks by which navigation can be kept open. Also the question as to what constitutes a navigable stream is one not to be decided offhand. Some streams float logs which float nothing else, yet logs are important to industry. Canoes and ocean liners alike bear freight, yet who is to be wise enough to state at what point the draught of a vessel decides the navagability of a stream?

The Sherman Act may act as a limitation upon power developments, for a very odd reason. To make this plain it will be necessary to say a word of the practice of "coupling" power stations, which may perhaps best be done by quoting from a government report on the subject. It is stated that it may occur, that of two power sites tributary to a given market, neither will meet the demand, whereas if both are used together they will. If, for example, there is a market for 5,000-horse-power and there are two accessible power sites, one capable of supplying 4,000 continuous horse-power and the other 1,000 horse-power, it is obvious that neither alone can meet this demand; but if the two should be "coupled" together the demand can be met. This may be called making the smaller site auxiliary to the larger. It is true that the power from both sites can reach the market and can, therefore, supply it even though they are not coupled. There would, however, be the expense of separate transmission and distributing equipment and separate management, and this expense might be such as to prevent the development of the smaller power.

### One Plus One Not Always Two

Again assume two sites, one capable of meeting the demand during the hours of minimum requirements and the other large enough to meet the maximum demand extending over, say, 10 hours. If the larger plant is kept in operation constantly, its pondage will be so reduced that within 24 hours or, at the longest, in a few days, it will not have sufficient power to meet all the demand. The smaller site can at no time meet the maximum demand. In this case neither site can separately supply the market all the time, but coupled together they can. Thus, if one site alone is able to meet the lowest demand and during this time the other plant can remain idle and accumulate water, this accumulation will contribute to meet the larger demand during the busiest period of each succeeding day. The principle is equally applicable whether the sites are on the same or on different streams, provided such sites are accessible to a common market.

It may not at first sight be plain why there is so great a saving as engineers tell us is actually made, when the coupling together not of two but of many plants is accomplished. But remembering that an isolated plant must be capable of supplying its maximum demand, which capacity is not used to the limit for more than two-thirds of the time, consider the testimony of Mr. C. C. Merrill of the Forest Service before the Committee on Water Power of the House of Representatives last year. Said Mr. Merrill: "The larger the power market served, the greater is the diversity of use, the more regular and continuous the demand, the higher the load factor, and the smaller the percentage of surplus equipment required. Eighty per cent of the electric power development of the State of Montana is in one single power system. The capacity-load factor for that state in 1912 was 58 per cent as compared with 26 per cent for the United States as a whole. Studies made in 1912 for the cities of New York and Chicago showed that the consolidation of the operating stations in the latter city would have saved from $10,000,000 to $12,000,000 in investment. Similar consolidation in the city of New York would have saved from $18,000,000 to $20,000,000 and would have reduced operating expenses by $1,000,000 a year.

### A Big Game for Big Players

"Had our railroad systems consisted of short, independent, competitive lines, each interested in serving its particular local territory, they would have been utterly helpless in the face of the transportation situation of the war-time period. Even as they were, further unification became necessary in order to meet the extraordinary traffic demands. Power development, particularly in the great manufacturing states of the East, where the greatest demand exists, is still in large degree in the primitive state of isolated independent development. Were these stations interconnected to the full extent which is now thoroughly practicable, hundreds of millions of additional kilowatt-hours of electric energy could be made available without the addition of a single dollar's worth of new equipment.

"While interconnection of stations is a measure of economy in steam-power development, it is a measure of necessity in any general water-power development, particularly in the eastern United States. No considerable development of eastern water power will come about except through interconnection of plants over wide territories in order that the diversity of demand in different markets and the variation in water supply at different sites may raise the load factor of the combined system to a point where steam-power competition can be met.

"On account of the extent of the territory which will be involved and of the fact that the power transmission systems must ignore State lines no authority less than that of the Federal Government will have sufficient jurisdiction either to conduct the investigations or to exercise control over the completed system. There is a transmission system already operating in California, the termini of which are as far apart as Washington is from Eastport, Me., or from Jacksonville, Fla. The future of water-power development in the East must be along similar lines."

Here is where anti-trust legislation is a handicap. Our nation after rioting in competition, passed to a great centralization of industry, only to become frightened at the power of even "good" corporations. Came the Sherman Act, and as we all know, the Standard Oil "trust" was "dissolved" and the packers are being made legally to behave and the steel industry escaped dissolution by the skin of its teeth and so on. Capital is afraid of an industry where combination is salvation, and independence, suicide. We must have vast power systems, linked together physically, in order that the fluctuations of demand on the one side and water flow on the other can be met. It is not feasible to interconnect dozens, perhaps hundreds, of power sites physically and not have that connection extend to some degree in the business relations. Legislators have done wisely, perhaps, to limit combinations of factories and businesses to the thwarting of competition. But that same limitation applied to water power may strangle not only the combination but the power.

### Where Congress Comes In

There have been very few developments of water powers in the last few years, largely because the country has been waiting upon Congress to pass a new water-power act which would clarify the situation and remove the difficulties from the path of development. A bill has been passed in House and Senate and is now in conference, from which it will emerge some time, possibly at this session, in what form no man knoweth. The bill is a weighty document, and considers so many features of water-power development that it cannot even be summarized here, but it does license water-power development for a period not exceeding fifty years and does provide that such license once granted cannot be revoked by any one man's authority.

The provision for control through the possibility or loss of license is simple and direct. It says: "That the Attorney General may, on request of the commission or the Secretary of War, institute proceedings in equity in the district court of the United States in the district in which any project or part thereof is situated for the purpose of revoking for violation of its terms any permit or license issued hereunder, or for the purpose of remedying or correcting by injunction, mandamus, or other process any act of commission or omission in violation of the provisions of this Act or of any lawful regulation or order promulgated hereunder. The district courts shall have jurisdiction over all the above-mentioned proceedings and shall have power to issue and execute all necessary processes and to make and enforce all writs, orders and decrees to compel compliance with the lawful orders and regulations of the commission and the Secretary of War, and to compel the performance of any condition imposed under the provisions of this Act."

The general public, of course, has little knowledge and less interest in questions of this kind, merely because they have not reached an acute stage. But power is to be the future warmth of this nation, and there are some resources which will never be developed without power, cheap power and plenty of it. We know how to make our own nitrates, yet Chili continues to be our nitrate bank. The air is free to all—the nitrogen we need for fertilizer and for munitions is four-fifths of it. It can be extracted and made useful. Give us enough cheap power and Chili can exhaust her nitrate beds for all we care.

### Power and Transportation

Transportation is the life blood of a nation. Our history has been a history of railroad development, now being paralleled by the construction of good roads and the infinite multiplication of self-moving units—trucks and automobiles. But the days of gasoline, at least at present or lower prices, are numbered. Some substitute must be found. Synthetic fuel can be made but the manufacture takes power. Shall we burn coal or oil to make another fuel to burn? Or shall we utilize gravity to drive our motor trucks *via* electric power made at the falls and converted in one way or another to the synthetic fuel which represents for us our only practical way of storing power?

If the United States is to continue in the future what it is now, as the leading manufacturing nation, and if it is to make full use of the greatest number and diversity of natural resources which an all-wise Providence ever provided for any country, it must use power in large quantities. That power nature has given us. The rivers are here. There are vast numbers of natural falls. Artificial falls but await the magic touch of the imagination and the engineer to come into being. Reclamation projects with their huge dams already use the water first for power, next for irrigation. Are we to neglect this, our greatest natural resource, because of economic specters, legislative ghosts, intangibilities like state lines, statutes like the Sherman law, enacted with no such idea in mind?

Here are we, owners in fee simple of millions of

(*Continued on page 72*)

*WHEN we have followed Mr. Claudy while he makes it plain that in the development of water power lies the only direction in which we may hope for relief from the prehistoric necessity of burning fuel when we seek heat or power; and when we have pursued his discussion of what constitutes water power and what does not—why, then, the natural question is, "Why have we not developed every bit of our available water power?" The answer to this question and to its natural companion, "What are we going to do about it?" form the theme of the present and last article in the series.*—THE EDITOR.

# Fighting Waves with Compressed Air

## An Artificial Reef of Air That Breaks Up the Rollers and Makes Them Harmless

By George F. Paul

THE use of compressed air to prevent piers from being demolished and shores destroyed by the merciless pounding of the breakers is a modern method that is proving successful in actual service. It took men a long time to figure out this simple yet effective means of making the mightiest waves as harmless as the ripples kicked up by a good stout fish. The compressed air fights its way to the surface of the water with a combined rising and explosive action. This breaks up the wave motion. The wave is simply confused—it cannot go ahead. It hesitates, curls over, breaks on the rising wall of air and water and then subsides with all its immense energy spent. Back of that point the water is protected, so that the shore is safe and vessels can ride undisturbed at anchor.

That the sea waves have the power to do tremendous damage is shown by repeated tests along various coasts, special instruments being used. The British Isles are among the greatest sufferers from the incessant pounding of the waves. Tests made along the North Sea coast showed a striking force of from three to four tons to the square foot. During a storm at Wick, huge blocks of concrete averaging 1,350 tons and 2,500 tons respectively were displaced.

Builders of sea-walls along the coasts of the United States have found that they had a powerful foe to deal with, and one that all too often got the better of the expensive defenses that they constructed. For instance, the actual value of property destroyed in the single town of Seabright, New Jersey, was enormous, and the sufferings inflicted on its citizens cannot be estimated. It would be hard to estimate the depreciation in property values along that part of the coast line, a depreciation shared by the lands not actually eroded, because of the apparent magnitude of the danger to which they are subjected.

It is because of these conditions that work has been undertaken to perfect compressed air apparatus that would successfully fight off these repeated encroachments of the sea. These experiments have proved very costly because of the large scale on which the work had to be done.

Now it has of course been long known that waves would break on a reef when they are of any magnitude and are in water of considerable depth. This is due to the interference with the continuity of the lower section of the wave action because of this sudden inequality in the floor of the ocean. Taking advantage of this fact, builders in Holland and England have constructed artificial reefs or wave breakers of random stone, with the idea of causing the wave to break on this and thus exhaust its force. Although this plan is efficient on some coasts, yet there are several objections to it. One of these objections lies in the fact that the stone reef interferes only with the lower layer of wave-action.

Theoretically it is a very simple thing to talk of the formation of an artificial reef at any point by using compressed air expelled from a perforated pipe lying on the bottom to form such a reef. There were, however, a number of practical considerations that had to be tested and worked out before such an idea could become commercially valuable. Some of the questions that came up immediately were these:

What would be the necessary amount of air required per foot of perforated pipe used to produce calm water?

How could this air be equally distributed?

How could this perforated pipe be prevented from filling with sand?

Obviously, the only way to answer such questions as these was to install such plants and watch the operation. The first tests were made on a muddy bottom in New York harbor at a depth of 30 to 40 feet to determine the most efficient size for the perforations in the pipe and their distance apart. A second trial was made at the end of one of the costly piers at Atlantic City, on a sandy bottom at a depth of 21 feet. The next test was made on "the stern and rock-bound coast" of New England, off Crotch Island, Maine. On the day of the trial, waves were rolling so high that the spray was flying over the tops of the trees along the shore. Fifteen minutes after the air was turned on, it was possible to paddle around in a canoe in the smooth water that the air breakwater furnished.

The U. S. S. "Yankee" managed to get ashore on Hen and Chicken reef in a very exposed position off the Massachusetts coast. Before the air was turned on, the seas were boarding the ship fore and aft, causing it to grind very much on the rocky bed and making it very difficult for the wrecking crew to do any work. After the air was turned on in the breakwater, it was as if the ship lay in a lagoon formed by the air breakwater.

The latest plant to be established was one in front of an expensive pier at El Segundo, California. This pier, which was originally 4,000 feet long, and has cost hundreds of thousands of dollars to build and maintain, had nearly 2,000 feet washed away in recent severe winter storms. To save the remainder of the pier it was decided to try the compressed air method. The plant consisted of three sections of perforated pipe, the first section of 120 feet being out in front of and at a distance of 145 feet from the pier head. The two other sections were 100 feet each and lay at right angles to the pier, one on each side, starting right from the pier head. Not only have these pipes kept the pier from being swept away, but they have also broken up the ground swell which so often interferes with the loading of vessels at piers along the Pacific coast. The swing of the boats alongside the piers has often been so strong that 14-inch manila lines have been known to be snapped like pack threads.

The Pacific coast is especially in need of some means for treating artificial harbors. There is not so much coastwise shipping as there undoubtedly would be if

### The High Cost of Milk

To the Editor of the SCIENTIFIC AMERICAN:

This household has been a subscriber of yours directly or indirectly through a local news agency for the past forty years. We have always found it a source of satisfaction to know that we possessed dependable information about our navy, the various great engineering undertakings, our coal or oil resources, besides greatly diversified mechanical information which is becoming so fundamentally necessary to a farmer living in these mechanical times.

I am merely a farmer, laboring long hours on a farm of some 350 acres. I have little time to read, but I keep in touch with the features of each issue as they appear.

In your issue of November 22, last, I was particularly interested in the article on "The High Price of Milk" by Alfred J. Lotka. Mr. Lotka's opinion is correct so far as it goes. The farmer can produce more milk and produce it cheaper by knowing his cows individually and by conducting his dairy operations scientifically as suggested; but if I were to write an article on "The High Price of Milk" I should not omit the most important part—the cost of distribution. Do you know that it costs more to distribute milk in New York City than it does to produce that milk and deliver it to New York? Do you know that farmers are actually penalized during nine or more months of each year for producing too much milk? In most cases the farmer has to part with this surplus milk at a considerable loss.

The farmer has not received the cost of production for milk, which has caused him to diversify his farming as much as possible. But now it appears that the labor situation may force the farmer to work on the basis of an eight-hour day or pay excessively higher wages for a longer day.

Within the past three years in this fertile Mohawk Valley I have seen the families on ten farms in this immediate community comprising 1,400 acres auction off their goods and move to the cities. On some of these farms it is now common to see large fields of 30 or 40 acres stand in weeds. These people had become tired of 12 to 16 hours a day of drudging, Sunday as well as Saturday afternoon, for less pay than they could receive in the cities for eight hours' work without any equipment. The whole trouble lies in your extravagant delivery system in the city. You have hundreds of wagons with their drivers that do nothing but deliver milk to the retail buyer for a few hours each morning. You have huge depots where these wagons load and to which they return and in which nothing but milk is handled. You have a vast organization that does nothing but buy milk from the farmer and deliver milk to the user and manufacture milk products out of the residue that remains undelivered.

How much do you think you would pay for your morning paper if the young fellow who leaves it at your door did nothing but deliver papers over his morning route? if instead of utilizing subway and every other existing facility the jobbers in this field delivered all orders to the retailers in their own trucks, used for nothing else? if instead of the regular news company that deals in weekly and monthly magazines and maintains stands that sell candies, tobacco, etc., etc., you got your morning edition through a news company with an equally ambitious organization, but dealing only in morning papers? Of course milk is a food, and a mighty important one, and of course the problems of producing and marketing it are complex ones. But with the example of the great packers before us, can we maintain that on this account the production and sale of milk ought to be asked to maintain such a large and exclusive establishment? I do not suppose, if you raked the city with a fine-tooth comb, you could find another industry in which the overhead expense and the invested capital bear so high a ratio to the wholesale cost of the product dealt in.

By all means let those who feel that their milk must come to them *via* a personally conducted tour in a private coach under the conduct of a special footman have their milk brought to them that way. But why should all consumers be asked to patronize this system? If it were not a sufficiently vicious one on the grounds I have already covered, it would be branded as intolerable by the domination which a reckless labor organization of drivers has attained over it. Think of it—fifty, sixty dollars a week for a service which in a simpler community did not exist. Why should milk be thus coddled, above all other foods? You buy meats and other perishable items that have to be put on ice, and you don't insist that they come to you ten minutes before you are ready to use them. A rational system of distribution through existing retail stores that dispense other foods—that is the real answer to cheaper milk. And until some such measure is adopted for freeing milk of the excessive overhead which it has to carry, and from the ruthless greed of an organization of the most unskilled labor that I can imagine, there will be little relief for the farmer or for the consumer.

We, as farmers, can live and maintain our health with conditions as they are, but Dr. Copeland, your health commissioner, will tell you that many children in your city will later become tubercular because they have suffered malnutrition due to a lack of milk during their growing years.

I trust you will appreciate the importance of this matter and will lend your good offices toward helping to correct this abominable situation.

Amsterdam, N. Y. D. BOYD DEVENDORF.

### The Airplane Cloud

To the Editor of the SCIENTIFIC AMERICAN:

On page 357 of the April 3rd issue of the SCIENTIFIC AMERICAN appears a paragraph under the heading "Cloud Formation in Wakes of Airplanes."

Although I have never heard the phenomenon described as it is in this paragraph, I have often observed it. Quite naturally, I always supposed it was an attenuated stream of smoke—rather than a cloud—visible only because of exceptionally clear atmosphere.

In July, 1918, I saw this cloud in the wake of an airplane flying about four miles high, over the Front at Albert, France. Then, during the last week in September and the first week in October, 1918, I saw the same thing several times near Verdun, France. In every case the cloud appeared exactly as it is described in the SCIENTIFIC AMERICAN although the lengths I observed were not as long as those mentioned. I estimated the lengths to be about five to ten miles.

Chicago, Ill. R. V. WILLIAMS.

# What About Our Forests?

## How Long Shall We Be Able to Cut Them Down Four Times as Fast as They Grow?

### By H. A. Mount

*THE situation in which the paper industry finds itself because of a growing shortage of pulp wood is indeed alarming. But this is only one aspect of the far-reaching problem of our dwindling forests. Few of us realize the extent of our dependence upon the forests for prosperity. The census bureau estimates that of 276,000 manufacturing concerns listed, 52,000 of them depend wholly or in part on a continued lumber supply for continued operation. These represent an investment of $3,000,000,000 and employ 1,130,000 men—one-sixth of all the workers in the United States. And the raw material which occupies such a place in our economy we are consuming four times as fast as Nature can replace it.*—THE EDITOR.

WE are using up our forests three times faster than they are growing and experts predict that in less than half a century our supply of saw-log lumber will be gone. White pine in the Lake states is nearing exhaustion and these states are now paying $6,000,000 a year in freight bills to import lumber. New England, self-supporting in lumber twenty years ago, now has to import one-third of the amount used. Half of the fir or balsam in eastern United States, which forms an important part of the timber supply there, is at this moment either dead or dying because of neglect. We provide insufficient protection against fires for our remaining forests and every year $20,000,000 worth of timber is destroyed in this way. The area burned each year is three times as large as the devastated sections of France and not only is the standing timber destroyed, but reproduction upon thousands of acres is killed.

These are just a few of the pertinent facts that are bringing about an awakening to the situation. The American Forestry Association of Washington, D. C., of which Charles Lathrop Pack is president, has actively begun a campaign in the Capitol for legislation providing a national forest policy, under which forests can be adequately protected from fire, conservative cutting can be practised, reforestation accomplished, and devastation stopped. They have been aided in their campaign by the daily press of the country, which has had the situation thrust upon it in a forceful way by an acute shortage of wood for making paper pulp. The newspapers, therefore, have been willing spreaders of needed propaganda.

But the destruction of our forests extends its results even further than the hampering of industry. It affects weather conditions, experts tell us. The increase in numbers of storms and tornadoes in recent years has been blamed, to some extent, at least, on the lack of trees. Forests regulate the flow of streams and the cutting of forests at the headwaters of navigable streams is sure to cause disastrous floods at one season and low water at another.

The Ohio River is a good example. Cutting of the forests in West Virginia has greatly affected the flow of the river. Every spring thousands of dollars worth of property and many lives are destroyed at Pittsburgh and Cincinnati, and at scores of other towns and cities along its banks, while in midsummer the river sometimes is so low that navigation is hampered.

In the face of these facts, it is hard to understand why we have so long neglected our forests. It is due, in a measure no doubt, to the lingering among us of the old Colonial notion that our forests are inexhaustible. But more likely it is due to a characteristic American aversion for spending money on operations where the profits are deferred many years, even for generations. Unlike the French, we acknowledge no indebtedness to posterity.

Our lawmakers have shown this very spirit and when a cry for economy is raised our already meager expenditure for forest protection is cut another notch.

And so we go blithely on, cutting down our timber four times as fast as it is growing and in spite of the fact that the Secretary of Agriculture estimates three-fifths of the country's original timber supply is gone. We are now attacking our last great reserve of timber—the forests of the Northwest.

The migration of the woodsman, from East to West, can be traced in statistics which are available since 1850. Then three-fourths of our lumber came from the Northeast and Central states. In 1918 the same states furnished 15 per cent of our lumber.

In 1850 the Lake states furnished 6 per cent of our lumber. In 1880 thirty-five per cent came from these states, in 1889 twenty-five per cent, and in 1918 ten per cent. In 1850 the South furnished 8 per cent of the lumber used, in 1918, 35 per cent. The Pacific coast gave practically no lumber in 1850, 15 per cent in 1909 and 27 per cent in 1918.

It will be seen that the principal supplies now come from the pine forests of the South and the great wooded mountain slopes of the Pacific states. But already the southern timber is nearing exhaustion and that will leave us principally dependent upon the Pacific coast forests.

The timber-using industries are located mainly in the East and long before the vanishing point is reached in our timber supply, the shortage will be keenly felt in increased costs, as the timber supply moves farther and farther away from the demand.

It must not be imagined that the entire East is denuded of trees or that there is no hope of reforesting there. About 60 per cent of

## Fence Posts That Don't Decay

Forest Service model illustrating the new method of preserving fence posts

DECAYING fence posts are familiar sights on thousands of farms, and when probably several million feet of timber is involved, the problem of preservation is one of magnitude. Obviously, every farmer cannot operate an expensive wood-preserving plant which would afford artificial treatment of the posts before they are planted in the soil. How, then, can the resisting-qualities of fence posts be strengthened against the attacks of a low form of plant life called fungi—decay not due to the chemical action of the soil, as is popularly believed?

The diminutive model, as herewith reproduced, is descriptive of a novel method designed by the U. S. Forest Service whereby farmers can lengthen the life of their fence posts by a simple treatment. Obtain four abandoned barrels, two of which are to be connected with a four-foot iron pipe; the other two containers being disconnected but in close proximity to the twin barrels. Coal-tar creosote, a cheap brownish-black oil, is prepared as a timber preservative. Once the fence posts are seasoned they are soused in the connected barrels where the wood receives a hot bath. A fire built under the connecting iron pipe supplies heat for the liquid inside the two containers. The two isolated barrels likewise contain a coal-tar creosote preservative, the posts being transferred from the warm temperature to these containers where they are given a cold bath.

Having been thoroughly immersed in the artificial preservative, the farm timber is piled, chicken-coop fashion, for drying. The creosote treatment qualifies in the essential requirements as a preservative of farm timbers: namely, reasonably cheap, capable of penetrating wood, not easily washed out of the wood, and poisonous to the lower plant life which so insiduously pursues its tactics in breaking down fence supports. By giving the posts a hot bath the air and moisture in the timber expand and are partially expelled; when plunged into the two barrels containing the coal oil the remaining air and moisture contract and serve to draw the oil thoroughly into every fiber of the wood.

The time required in administering the simple treatment is largely gaged by the rapidity of penetration and the quantity of oil absorbed. Preliminary experiments suggest that the hot bath should not extend over three hours, with an equal period of time allowed for the cold bath. Seemingly paradoxical is the statement by the Forest Service that the most efficient treatment is the one affording maximum penetration of the substance of the wood, but with a minimum of permanent absorption of oil.—By *F. W. Hyde.*

A model designed to show the effects of tree cover in preventing the erosion of the land surface

## Geology and Forestry

AMONG the educational exhibits to be found by the visitor in Washington, few are of greater interest or value in their field than those which the Forest Survey has constructed to show the influence of trees and forests upon the action of various geological agents which have contributed to the making of the earth's surface what it is. An idea of the size and character of these may be obtained from the accompanying picture, which displays the model designed to show the effects on erosion of land surfaces. The immediate lesson which this model is intended to emphasize is the influence of trees in preventing erosion; hence the barren stretch which has been washed clean of all soil, and the tree-covered regions above where the destructive faculties of water have found little scope. Between the two areas in question there stands what is represented as a middle ground—temporarily. With its trees cut off and nothing standing on it but stumps, however, it is very plain to the most casual inspection that this section will take on the aspect of the lower level, and within a space of time which, geologically speaking, amounts to nothing at all. A better object lesson of the ultimate consequences of the indiscriminate deforestation which so large a part of the West has suffered could hardly be imagined.

The old road and the new at a point where a simple operation eliminated a sharp curve overhanging a steep bank on this much-used highway

## Ironing Out a Dangerous Curve

DANGEROUS stretches of highway are not uncommon but in the elimination of "Dead Man's Curve," on the Washington-Baltimore boulevard, near Elkin, Howard County, Maryland, there remains only a shameful memory of one of the most perilous roadway curves in the United States. Some six or eight persons met tragic endings while thirty-five more or less serious accidents were recorded before the change was made. The original curve extended for a distance of 1,150 feet, and automobiles being directed around the sharp turn were frequently driven over a steep incline or embankment. A vision blurred by the road was likewise frequently impaired by autoists imbibing too freely of intoxicants, when prohibition in Washington, D. C., drove them to Baltimore—all contributing to the menace of "Dead Man's Curve."

The State Roads Commission of Maryland authorized the elimination of the perilous stretch at a cost of $17,000—an insignificant consideration when compared with the toll of life which it annually exacted. The bank at the sharp bend in the road was cut away from the inside of the curve toward Baltimore, the soil being used in making a fill, thus straightening the western end of the dangerous stretch. The curvature at this point has been reduced from 110 to 60 degrees, facilitating an enlarged vision all along the changed location. The new slice of roadway is constructed of concrete and is 20 feet wide.—By *S. R. Winters.*

## Purple Dye from Shellfish

ON the Pacific coast of Costa Rica, especially in the region about Cocos Bay, there abounds a kind of shellfish called the "nacascol," from which a fine purple color is obtained. So far no way has been found for preserving this dye, and the industry has remained in the hands of the few old people who take the trouble to dye a few ounces of thread every summer. The process is very simple. On picking up the shell from the beach or detaching it from a bowlder, the gatherer blows her breath into it, whereupon a few drops of a greenish liquor ooze out. This liquor is collected in a clamshell, and after a sufficient quantity has been collected the thread is passed through it, very soon assuming on exposure to the sunlight, a beautiful purple color, which is absolutely fast after it has turned purple. It is thought possible that the dye turns fast only on exposure to the air and that the liquor could be preserved by keeping the air away from it. There is little doubt that this industry of dyeing thread could be extended to greater proportions if an extensive demand at good prices could be found for the dye-stuff.

## Protecting Peach Trees from Worms

THESE darkies are neither hunting for four leaf clovers nor practising for a revival meeting. They are worming peach trees in order to prevent the costly losses which result from the activities of peach tree borers. The earth is removed from around the crown of each tree to a depth of four or five inches and the trunk brushed or scrapped free of loose bark and dirt. The darkies armed with knives, stiff wires and suitable gouging tools locate and remove and destroy the borers which are fortified in their burrows. Special care must be exercised not to cut the sound bark or wood unnecessarily as carelessness may cause more damage than would result from the insects themselves. After the worming work is completed, the earth is mounded up around the tree to a height of 8 to 10 inches. The base of the tree is also often whitewashed to further protect the trees against peach borers.—By *A. R. Surface.*

The 23-meter trial horse — Challenger: "Shamrock IV" — Defender: "Resolute"

**America's Cup racers of 1920**

# "Resolute" Defends the Cup

## Why "Resolute" Was Chosen and Her Prospects of Defeating "Shamrock IV"

### By J. Bernard Walker

ALTHOUGH a great many yachting enthusiasts will be disappointed that "Vanitie" was not chosen to defend the America's Cup, we are in a position to state that the selection of "Resolute" was made strictly on the merits of the two yachts. The Cup Committee realized that the challenger was too fast a boat to allow of any but the very best of our craft being sent on to the Sandy Hook course to meet her; and in trying out "Resolute" and "Vanitie" this year, there was never at any time a thought of playing any favorite—much idle talk to the contrary notwithstanding.

The proof that the Cup Committee was impartial in its treatment of the two defending yachts is to be found in the remarkable improvement shown by "Vanitie" since she came unreservedly into their hands. During the racing of 1914 and 1915 she seemed to be a hopelessly beaten boat; whereas by the close of the 1920 trials, she had several impressive victories over "Resolute" to her credit, and had proved to be so close a match for the Herreshoff craft that in any true wind, whatever its strength, the issue was in doubt until the yachts were over the finish line and the corrections for time allowance had been made.

Never in all the seventy years that have elapsed since the "America" sailed her historic race has a Cup Committee been confronted with a more difficult task in selecting the defending yacht, and the decision was arrived at only after an exhaustive analysis of the results in all of the 1920 trial races. In the first place, all races in which the vagaries of the weather vitiated the result were promptly ruled out of consideration; and a careful analysis was made of the relative performance under conditions when the wind and weather were equally favorable to both boats. Each leg of every course sailed was thus studied and the final choice was made on the total number of points scored by the two yachts. The outcome showed a slight advantage in favor of "Resolute."

To this must be added certain physical characteristics, the consideration of which scored in favor of the selected boat and marked her out as having that slight margin of superiority which might mean the difference between winning or losing. For it must not be forgotten that cup races have been won by 40 seconds, as in 1895 ("Vigilant" against "Valkyrie II") and by 41 seconds, as in 1901 ("Columbia" against "Shamrock II").

At the present writing "Shamrock IV" has shown such a decided superiority over the 23-meter boat that the races between the two have been discontinued and the crews of the boats are being trained in teamwork on the challenger. The failure of the older boat to push the challenger more closely is surprising; for in addition to the fact that in 1912 and 1913 she beat all competitors, winning on time allowance against larger craft and saving her time allowance against smaller boats, she is somewhat faster today than she was then.

This is due to the fact that she was handed over to Mr. Nicholson to make any changes he thought fit that would increase her speed as a trial horse for "Shamrock IV." To this end he added several tons to her lead and lowered its center of gravity. Like all boats built under the International rule, the 23-meter boat had a considerable rocker to her keel, which was 22 inches higher at the forward end than at the stern-post. As she now stands, the bottom of the keel is level. Several tons were cut from the ends of the old lead and this, with the additional lead, was molded on the bottom—the new lead tapering from 22 inches depth at the forward end to nothing at the stern-post.

The additional stability thus secured made possible a large increase in the sail area, so that with all her kites set, the 23-meter boat has nearly as much sail area as "Shamrock IV." She is also eighteen inches longer on the waterline—and length means speed. Her displacement today is 115 tons as against 106 tons for the challenger.

In spite of these changes the new boat, in a topsail breeze seems to be able to beat her about 12 minutes in a 15-mile turn to windward. In a run of 15 miles down the wind, she seems to have an advantage of two or three minutes.

In answer to the question why she cannot pull out a greater lead when reaching and running, we quote a remark of Charlie Barr to the writer: "Any old hooker can go fast down the wind; it's good windward work that wins races."

On the one occasion when the two Shamrocks were tried out in a wind sufficiently strong to call for lower sails only, the old "Shamrock" crossed the line slightly ahead and with the new boat tucked squarely under her lee. Under the stiff wind, the new boat, with her larger sailspread, showed in the puffs fully five degrees greater angle of heel, and both were smoking along at their top speed. "Shamrock IV" pulled clear and showed a gain of 2½ minutes in the six miles to the weather mark; the equivalent of 6¼ minutes in fifteen miles—a remarkable achievement, considering the high rate of speed. Coming home before a freshing wind she gained at the rate of 1 minute 40 seconds in fifteen miles.

And now as to the outcome when Nicholson, a new man in these International contests, meets Herreshoff off Sandy Hook. The 23-meter boat, under her 1912 trim, frequently made an even 12 knots on certain stretches of the course. She is somewhat faster today and "Shamrock IV" has her measure by a good margin on any point of sailing. But "Resolute" has frequently made 12.25 knots for several miles on end.

Let us suppose that "Shamrock" has to allow "Resolute" six minutes over a 30-mile course, say to windward and leeward, and that "Shamrock" barely saves her time—the weather conditions being such as bring out the best speed of both boats. Let us suppose

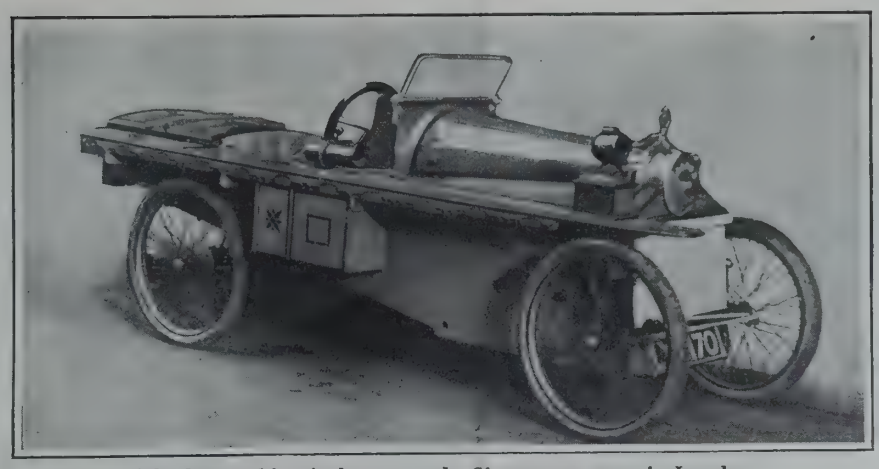
## The Home-Made Car

THE mechanically-inclined young chap who insists on making all his own things is always with us. In the old days he used to make his own bob-sled and his own racing sulky and above all his own sailboat. Then the gas engine came in, and he began making his own motor boat and before long even his own engine. Today he is busily engaged in assembling his own automobile and his own airplane. Wherever we go, we see among the vast concourse of big and little cars of standard makes a few of these low-hung, spider-webby affairs built to accommodate an engine and as much of the anatomy of a speed-maniac as can be crowded into them.

Much attention was recently attracted in the streets of London to the home-made speed bug which we illustrate herewith. The owner and builder seems to have had a talent for pattern-making as well as for machinery, and has made his body of hard wood, picturesquely carved and decorated. The engine and the assembly of the various moving parts presents no feature of startling novelty, although as little cannot be said for the position of the mud-guard. Another ingenious stroke is the use of an ordinary window shade on a roller to prevent the radiator from doing too good a job and cooling the engine below the point of best operation.—By *Ralph Howard.*



The latest thing in home-made flivvers, as seen in London

## Sea Gulls Make It Necessary to Cover Reservoir

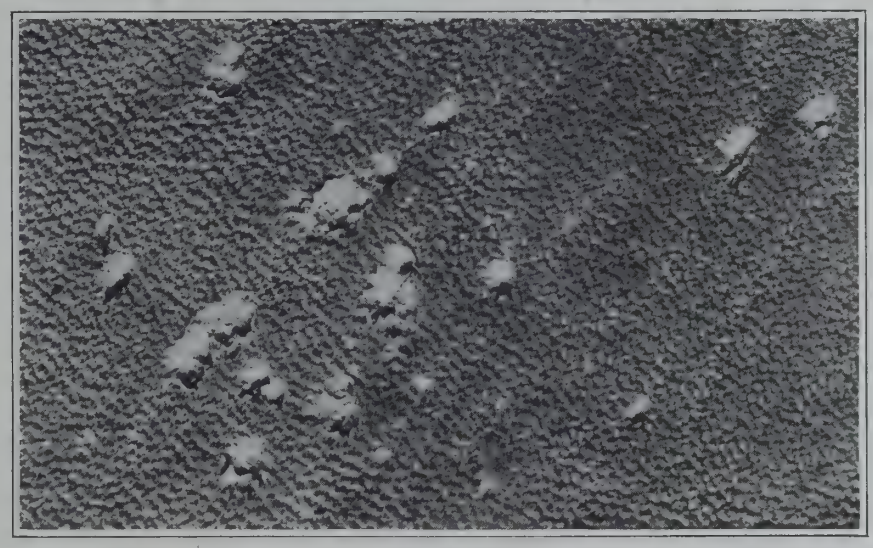
THE reservoir of the California water company shown in the accompanying photograph was built in the 50's, but recently because of the sea gulls' becoming such a nuisance it became necessary to cover it. The reservoir has existed for all these years within a few blocks of San Francisco Bay, but apparently was not discovered by the sea gulls until the latter part of 1918, when all at once they began to infest it, making it necessary to place guards around it to frighten them away—it was against the law to injure or kill them. What caused the gulls to seek the reservoir is a mystery. They came in such numbers that it was finally found necessary to cover the reservoir. With the completion of the roof over the reservoir a few months ago, the gulls departed as suddenly as they came. The reservoir supplies drinking water to certain sections of San Francisco, and for this reason it was necessary to take this course of action.—By *C. W. Geiger.*

San Francisco's reservoir that had to be covered to protect it from the sea gulls

## What the Cattle Tick Does to the Hide

THE educational activities of the Department of Agriculture have made it pretty generally understood that the discomfort suffered by an animal that is infested with fleas or other parasites is by no means the end of the matter—that the financial damage suffered through the deterioration of the creature's general tone by this discomfort, and through the actual physical ravages of the parasite itself, often make it well worth the raiser's while to spend time and money in the effort to free his flocks or herds of the objectionable guests. The photograph which we show herewith affords a striking illustration of this.

The cattle tick, of course, is known by all of us to be an insect pest that lives by sucking the blood of its bovine hosts. But perhaps it does not always occur to us that the skin of a full-grown bull or cow is a decidedly formidable affair, that in order to penetrate this skin and get to the place where the blood is to be found the tick has to do a good deal of excavating, and that when it comes to making leather of the victim's skin the marks of this excavating offer an obstacle. As a matter of fact, the holes made by the ticks in their search for nourishment are responsible for a reduction in market value that averages two dollars for each tick-bitten hide. The extent of the damage may be better understood from examination of the photograph.—By *A. R. Surface.*



What the hide of a bull looks like after the ticks have done their work

Berlin establishment in which clothing for the needy is made from discarded military articles

## Plastic Dressing for Wounds and Burns

INDUSTRIAL plants are now using the ambrine treatment for burns, scalds, and all surface wounds which proved very successful for casualties incurred in the world war.

The dressing is a compound of wax and resins, and is solid when cold. It is heated to about 150 degrees Fahrenheit, and applied by means of a special atomizer, or it can be gently daubed on with a soft brush. A plastic dressing, impervious to air, is thus formed, which does not adhere to the wound and which promotes the healing process without appreciable contraction. Disfigurement and scars are prevented to a greater extent than was possible under the old methods.

The outfits can be purchased in two sizes at $17.50 and $47.50 each, and will no doubt be found valuable in first-aid dressing in metallurgical plants, particularly for burns.

## Gas Masks in Pulp and Paper Mills

GAS masks of a nose-breathing type with canisters containing special chemicals are used in the digester house of the Forest Products Laboratory to give protection against sulfur dioxide. These masks enable the operator to make repairs under conditions otherwise unbearable and soon pay for themselves in time saved. Masks of this type are reported by the Bureau of Mines to hold up against a 5 per cent concentration of sulfur dioxide for about 15 minutes. When it is realized that 5 parts of sulfur dioxide to one million parts of air can readily be detected, and that at a concentration of 150 parts of sulfur dioxide to one million parts of air the air becomes unbreathable, some idea can be gained of the life of a canister even under adverse mill conditions.

In addition to their use in the sulfite mill, these masks are of great assistance in the bleach room, where they are worn continuously during the mixing of the bleach liquor. Aside from monetary considerations, the increased comfort and safety of the workmen is sufficient argument in favor of the addition of gas masks to the regular mill equipment.

## Working Over the Salvage Pile

THE salvage of discarded army supplies was a game which, as everyone knows, was freely played in France during and immediately after the war; but it may surprise some to learn that it is still being done in Germany. The workroom shown in our photograph was established in Berlin early in the war in the interests of the unemployed, who were here set to work renovating worn-out uniforms, shoes, etc. It has been continued, and others opened, not so much for the sake of making employment as to render it possible for the worst-hit of the city's poor to be clothed. In these shops about a thousand persons, mostly women, are now engaged working over the discarded clothing, hospital linens, gas masks, etc., into wearing apparel and other useful articles, which are sold at rock-bottom cost prices to the people who need them most. The position of those unfortunates whose income has remained practically fixed and who have not the ability or the enterprise to supplement it from irregular sources is so desperate in Germany today that but for measures of this sort it would not be possible for them to exist. When it takes a year's earnings to buy a semi-respectable suit of clothes, anything in the way of a substitute is more than welcome.—By *James Anderson.*

**How grain arriving in Chicago is sampled and tested to see that it is up to grade**

# The Man Behind Our Daily Bread

## Grading and Testing Grain for Sale on the Grain Exchanges of the Country

### By Robert H. Moulton

IF you visit one of the large grain exchanges of the country, like the Chicago Board of Trade, for instance, you will see on the trading floor long lines of tables on which are numerous small paper bags containing samples of grain. You may or may not know that these samples came from cars in the freight yards of the city where the exchange is located, and that they are used as a medium by which the entire carload lots are sold and bought. But concerning what happens to these samples before they reach the exchange you are apt to know nothing whatever. As a matter of fact, even the average farmer who raises wheat, corn, oats or some other grain, and who is therefore the person most concerned, has little idea of how his grain is handled after it is shipped from the farm and reaches a terminal market.

Before the samples of grain are displayed for sale on the exchanges they must pass through an intricate process of grading and testing according to rules formulated by the Federal Government. Each state in which the big terminal markets are located, such as those at Chicago, Omaha, Minneapolis and Kansas City, has an official grain inspection department whose duty it is to grade and test every car of grain arriving at that market. By "grade" is meant the quality of the grain as established by the Bureau of Grain Standardization of the Department of Agriculture. Thus, both wheat and corn have six grades, ranging from the best to the poorest, which accounts for the fact that one farmer may receive a better price for his wheat or corn than a neighboring farmer who shipped a similar lot of grain to market at the same time. One may grade high and the other low, and this naturally affects the price paid for it by the grain dealer who buys it through the commission men on the exchange. This difference in price may amount to several cents a bushel.

Practically all of the grain raised in the United States except that used for local consumption is sold on the exchanges. The reason for this is that these institutions furnish a world market. The exchanges themselves do no business, but merely provide a place where buyers and sellers the world over, through their representatives, may meet and trade. In doing so, they perform a valuable service to producers and consumers alike. Most of the grain produced in the United States must be handled within a few months. This means that about one billion bushels of wheat, three billion bushels of corn, and one billion bushels of oats, besides smaller quantities of rye, barley, etc., must be distributed evenly. If there were no machinery for this purpose, there would be hopeless congestion followed by long periods of dearth. The grain exchanges for the country furnish such machinery On the Chicago Board of Trade alone more than 400,000,000 bushels of grain are bought and sold each year. This refers to "cash" grain.

*THE housewife who buys food for a large family knows well that only in eternal vigilance is to be found the road to safety. She is well aware that if she does not scrutinize with care everything that she selects, and scrutinize with equal care everything that is delivered to her, she will not get the best grades. She knows that most of the merchants with whom she deals must as a means of avoiding loss sell the seconds and the goods that have got stale or wilted since receipt, and that they will land her with her share unless she is prepared to meet them on their own ground. How, then, she might ask, could she ever be sure of getting what was coming to her if she had to bargain for her purchases weeks and months ahead, without ever seeing them, and if she had to accept delivery from a fifth or sixth assignee of the sales contract which she had signed so long ago? Unless some satisfactory answer to this question can be framed, it must remain a mystery how the grain exchanges, which do business on precisely this future basis, are able to exclude crooked work from their dealings. In this story Mr. Moulton tells us how it is done, how the buyer knows when he contracts for grain just what is coming to him, and how it is made certain that he gets it.*—THE EDITOR.

Now "cash" grain might mean little or nothing to the outsider, but to the man in the trade it means grain intended for immediate delivery; that is, grain which is actually in cars or elevators in the terminal markets, and which can be delivered immediately to a purchaser. There is another department in which grain is bought and sold for "future delivery" but that is merely another chapter of the same story.

The Illinois State Grain and Inspection Department, which prepares samples of grain for sale on the Chicago Board of Trade, has frequently handled more than 30,000 cars of grain in one month, and its record for a single day's work done is 2,520 cars, of which 1,472 were corn. The latter is more difficult to grade than any other grain, as it requires the moisture test recently established by the Federal Government. The offices of the Grain Inspection Department in Chicago employ 25 deputy inspectors, 50 grain samplers, and a large clerical force.

Early every morning the grain samplers go to the freight yards where cars of grain have arrived overnight and take samples of each car. The sampling is done by means of an instrument known as a "trier," which consists of a 2-inch metal pipe 6 feet long, with a pointed end, in which are cut, at intervals of five inches along one side, eight holes about 4 inches by 1½ inches. A smooth wooden pole fits snugly into the pipe, closing all the holes. In using the "trier" it is shoved into the grain, down to the bottom of the car, and the pole is then gradually withdrawn, opening the holes, and allowing the grain to enter the pipe from various openings in the trier. The sampler is thus enabled to get a sample that will determine whether or not the grain in the car is all of one quality.

The sample thus taken is placed in a cloth bag together with a ticket on which is marked the initial and number of the car, and a notation showing the condition of the car at the time the sample was obtained. These sample tags are carried to the offices of the State Grain Inspection Department and the grain therein is inspected and graded by expert graders. A grain inspector must possess good eyesight, a keen sense of smell and a very acute sense of touch. These qualities are of vital importance, especially in the inspection and grading of wheat. The inspectors are all men of practical experience in the grain business who have passed rigid civil service examinations under the supervision of the Illinois State Civil Service Commission. These men stand before large tables on which the sample bags are placed. The inspectors open the bags and pour the grain into pans especially made to receive the contents of the bags. These pans are provided with funnel-shaped ends so that the grain may easily be poured into the

## The Akron-Detroit Dirigible Express

A BIG step forward in the development of commercial aviation in the United States is about to be taken by one of the big mid-western rubber concerns, which has purchased a Chalais-Meudon dirigible from the French government, and plans in September to establish the first inter-city airship line. Daily round trips will be made between Akron, the headquarters of the rubber industry and a place which most of us are only now learning in the light of the census figures to recognize as a city of the first class, and Detroit. For the first month or so, while the route and the ship and the navigators are being tried out, it is planned to carry only mail and express; after that it is probable that a passenger service will be attempted.

The airship to be employed has 320,000 cubic foot capacity, is 260 feet long and motored with two 250-horse-power engines which will drive it at a maximum speed of about 50 miles per hour. The cabin is 45 feet long, and when changed from its present war-time design to that of commercial construction it will accommodate about thirty passengers.

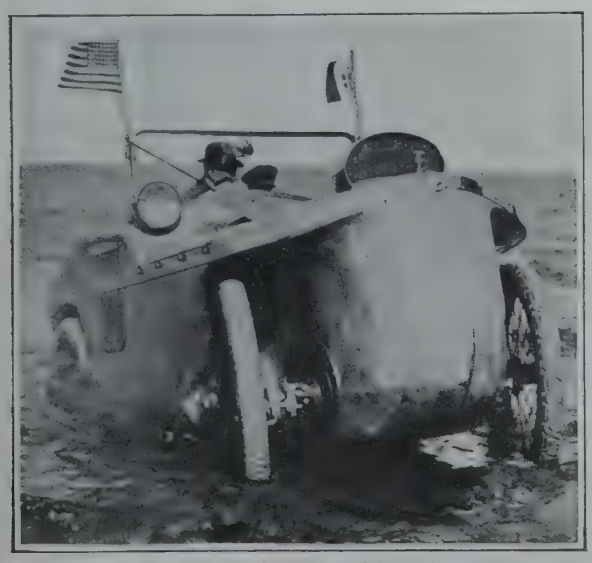
This ship was built for use in the war, of course, but was completed too late for service. No time schedule has been made up for the 150-mile trip between Akron and Detroit, but it will of course be much faster than the rail trip. The former United States Navy air station at Wingfoot Lake, Akron, has been secured for one terminal, and pending the arrangement of suitable housing in Detroit it is anticipated that a mooring mast will be used. Surely two cities with more interests in common than the automobile and the tire centers of the universe could not have been selected for this first effort at regular commercial airship communication—nor two cities whose present facilities for communication are more in need of improvement.

## The Sea-Going Automobile

WHAT with the hydroplane and the flying boat, we have a multiplicity of machines that are designed to discharge more or less satisfactorily the dual function of airplane and motor boat. But what shall we say of the bold constructor who puts forward a combination of automobile and speed-ship?—a motor car-boat, perhaps we may call it.

The interesting machine which is illustrated herewith is the "Sirena," and is now on exhibition at Atlantic City. It is a fully equipped motor car capable of making the speed of sixty miles an hour, anything less than which is today unworthy of the term of speed in land propulsion. It differs in design from the conventional car mainly in the very substantial bottom, the reason for which is immediately apparent when we reflect upon its secondary use; the ordinary carburetor, magneto, etc., would hardly function to the satisfaction of a particular driver if the car in which they are mounted were submerged to the gunwhales, and the spark-plugs might likewise have something to say about this semi-aqueous mode of operation. However, with the cruiser bottom with which this machine is supplied, she takes the water very nicely. A simple clutch throws the transmission off the wheels entirely and starts the engine to driving a propeller at the rear of the body—which, believe it or not according to your individual predilection, the maker assures us is absolutely watertight. As a boat the strange combination is capable of a speed of 20 knots. For those who insist upon sedan or limousine, the manufacturers say that they expect shortly to have such models.

We do not know just how popular this idea is going to be with the tire manufacturers, but perhaps if the front-wheel suspension will stand it the tires can be lepended upon for good performance.

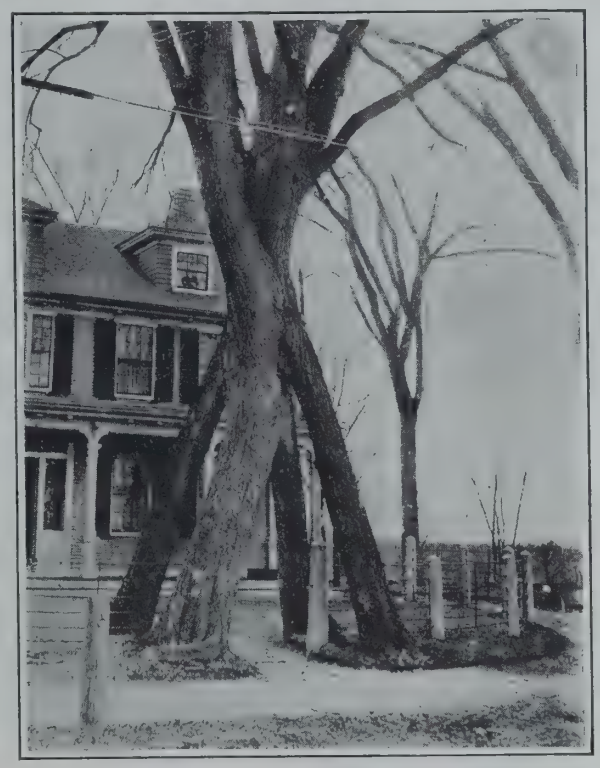


**An automobile on land—a speed boat in the water**

**The airship of French design with which it is planned to start regular service between Akron and Detroit**

## A Tree with Four Legs

NATURE has produced many freak trees, but one of the oddest forms ever created by human action is a four-legged tree standing at the entrance to the home of a Bridgewater, Mass., man. This tree has all the appearance of a single tree trunk with four spreading legs. As a matter of fact, the trunk is the combined trunks of four white elm saplings planted in a group and bound closely together about twelve feet from the ground, a good many years ago. In time the trunks grew into one, and this strange arboreal quadruped is now a large and sturdy tree. It is known locally as the "wishing tree," the legend running that a wish made while one is walking in and out among the four legs will come true.



**Demonstrating that a quadruped is not always an animal**

## Wood Firing on European Locomotives

IN Sweden, as in Switzerland, because of the fuel shortage, as a temporary measure, locomotives had to be fired with wood. The experiments made in the latter country were comparatively successful. The start was made on the Bodensee-Taggenburg Railroad, where steam was got up by means of wood firing, resulting in a pressure of from 5 to 6 atmospheres derived from one cubic meter of wood. Not only was the cost fifty per cent less than that of a similar quantity of coal, but the time required for getting up steam was shortened. Consequently firing by means of wood was instituted for the trip; but difficulty was encountered in finding sufficient room for the amount of wood needed. Finally, special cars were added to the trains to carry the wood.

The wood is cut into blocks and burned the same as briquettes. The same high class service resulted as if coal had been used. Four square meters of first class beech wood or five cubic meters of mixed wood (beech, pine, etc.) were about equivalent to one ton of first class coal. An average train required 152 tons and 68 cubic meters for 1,000 train kilometers; 16 tons of coal would have been required for the same trip.

Because of the high price of coal in Switzerland during the war, the firing of trains by means of wood proved to be an economic success. A disadvantage lay in the stream of sparks caused by the burning wood. The addition of pitch, which possesses from 7,500 to 8,000 calories of heat, is quite successful.

## Dehydrating Crude Oil Electrically

CRUDE oil often contains water which must be removed and this is not always easy. The usual methods are the application of heat, centrifugal force or chemical action. A new method is by the use of electricity which has proved superior to the others.

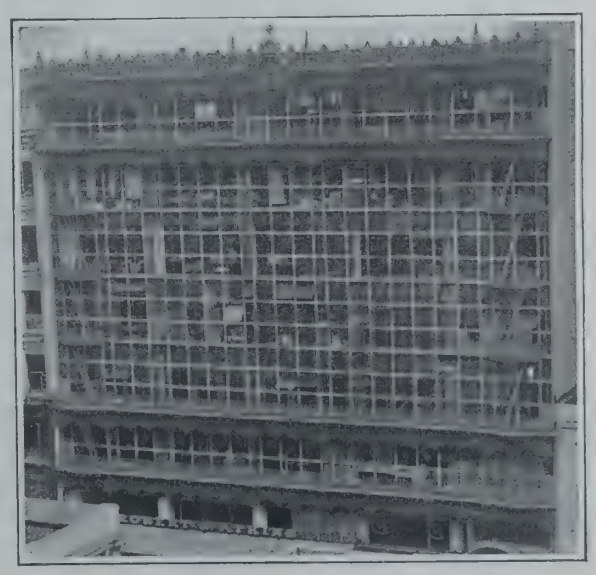
When present in the form of large free globules, water will settle out from oil by gravity, but if the water is in a state of emulsion with the oil, it will not settle out at normal temperatures and pressures, even if the mixture be allowed to stand indefinitely. The removal of water at the well effects an important reduction in freight costs, besides eliminating the clumsy practise of allowing purchasers a rebate on the percentage of water which they were able to prove was contained in the crude oil hitherto delivered.

There are 17 electrical dehydrating plants now operating in the Whittier District in California, and in many cases oil hitherto unfit for use is made marketable by electrical dehydration. The oil treated ranges from 15 to 50 per cent of water, and the consumption of electrical energy is about one kilowatt-hour per 18 barrels of dry oil. The electrical dehydration causes practically no loss of gasoline, and the gravity of the oil is raised one or two degrees by the treatment. This increases the value of the oil sufficiently to pay all or part of the cost of treatment. The heating process, on the other hand, involves more or less deterioration of the oil. Careful tests indicate that, under the same conditions, the heating process costs 7.5 cents per barrel, compared with 1.5 cents per barrel (or 2 cents, including royalty) for the electrical process.

Usually, the electrical dehydrator operates on single-phase alternating current at 11,000 volts. The emulsion of oil and water is passed between highly-charged electrodes, and the effect of the electrostatic field is to coalesce the particles of water and also coalesce the particles of oil. The water then settles readily by gravity. The average maximum demand per dehydrator is 4 kilowatts, the average load factor 50 per cent, and the average power factor 98 per cent leading. In districts where water is scarce, the water separated electrically has considerable value.

## People Who Live in Glass Houses

IF there is anything in the old saw, the proprietors of this big clothing store in San Francisco will have to be very circumspect with regard to the hurling of missiles. They boast that their street-front is "all glass," and it comes about as close to justifying the claim as any type of construction that we have ever seen. It is to be hoped that the Golden Gate does not become the scene of a repetition of New York's "Black Tom" explosion, which blew out windows twenty miles away—if it does, we can see where there will be work for the California glaziers. But even such a disaster might be a fair price to pay for the extraordinary lighting which the interior of this building must enjoy.



**A San Francisco store with an all-glass front**

# The Motor-Driven Commercial Vehicle

Conducted by MAJOR VICTOR W. PAGÉ, M. S. A. E.

*This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The editor will endeavor to answer any question relating to mechanical features, operation and management of commercial motor vehicles*

**A short cut from digging bucket to truck**

## Economical Truck Loading

THE illustration herewith shows a five-ton truck of standard make used by a contracting firm in Cleveland, and shows how a simple and rough hopper structure can be utilized in loading motor trucks economically when these are employed in hauling away excavated material. As will be evident from the illustration, the hopper is loaded by the usual form of clam-shell excavating-bucket, which in this case is handled by the conventional form of steam-operated derrick boom. The hopper, which has a capacity for several truck-loads of material, is carried on substantial columns of such height that it is an easy matter for the truck to back down underneath the loading chute. The floor of the hopper is inclined sufficiently so that as soon as the hopper gate is opened the material will drop down the chute into the truck body. It will be apparent that trucks may be loaded as fast as they can be driven under the chute. The surplus capacity of the hopper makes it possible for the clam-shell bucket to discharge its load even if there is no truck waiting to receive the material.

## Improved Type Combination Farm Body

THIS body is of the combination stock-and-grain type of especially heavy construction. The bottom panel is 14 inches high, being built solid to the body. As illustrated in the photograph the stock rack, which is 50 inches high, is constructed to be lifted off by one man, either in sections or as a unit. When off, this rack is replaced by a 10-inch grain panel which is shown in the photograph. This forms a solid grain body. The stock rack is equipped with a hog gate in the rear which can be entirely removed if desired. The sills and sub-sills of the combination body are constructed entirely of heavy kiln-dried oak, while the panels are built of genuine yellow poplar.

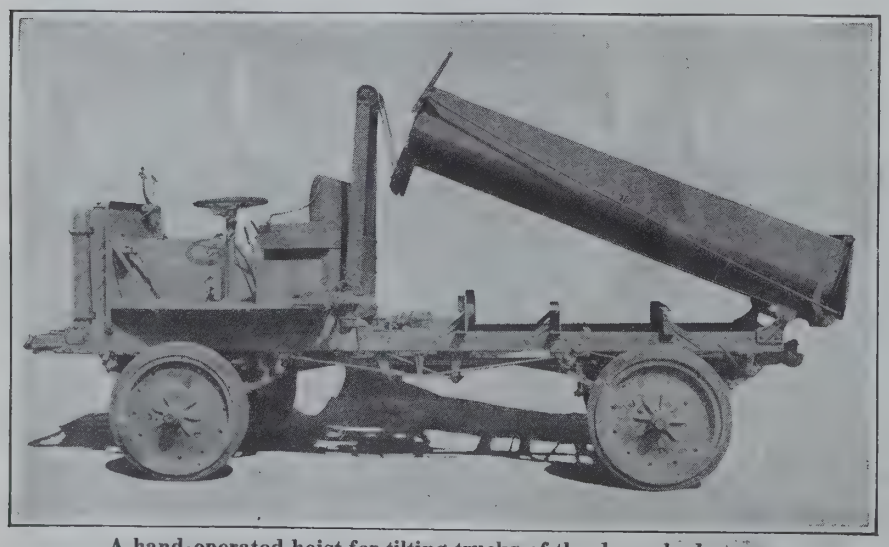
## Draw-Bar Pull of Trucks

ILLUSTRATIVE of the pulling power of the motor car over the horse, the Labor Day parade of a decade ago was not complete unless one float consisted of an automobile, dragging a trailer on which a dejected horse or two were trying hard to maintain their equilibrium. Now is presented the picture of the pulling power of a motor truck, which towed a huge freight locomotive for two city blocks without any difficulty. It was a five-ton truck that did the trick and the place was Seattle. The demonstration of pulling power was arranged

**Showing what a truck can do**

as the result of a wager between the division freight and passenger agent of the St. Paul Railroad and a prominent automobile enthusiast.

The locomotive's weight was 309,480 pounds and the truck weight less than one-thirtieth as much. To give the truck traction it was loaded with nearly five tons of cement and was then backed to the front of the engine. Heavy chains were used from the draw bar of the locomotice to the truck frame. The skeptical one signaled the start and the truck moved forward. There was an instant's halt as the dead weight of the locomotive resisted movement and then the steam engine began to move slowly. The rest of the two block tow was naturally uneventful, the engine following the truck easily enough after the initial resistance of starting was overcome.



**A hand-operated hoist for tilting trucks of the dump-body type**

**Combination body that serves all purposes about the farm**

## Heavy Duty Tractor

ILLUSTRATIONS have been presented from time to time in these columns to demonstrate the utility of the various forms of tractors and semi-trailer outfits in hauling large loads of various classes of material. The accompanying illustration depicts a semi-trailer outfit owned by a San Diego, California, produce company, which operates about the city carrying big loads of produce that come in by boat and train to the commission houses. One of the big advantages of the use of the tractor and semi-trailer outfits similar to that illustrated is that it is not only possible to handle large loads but that the trailers are

**The semi-trailer in close quarters**

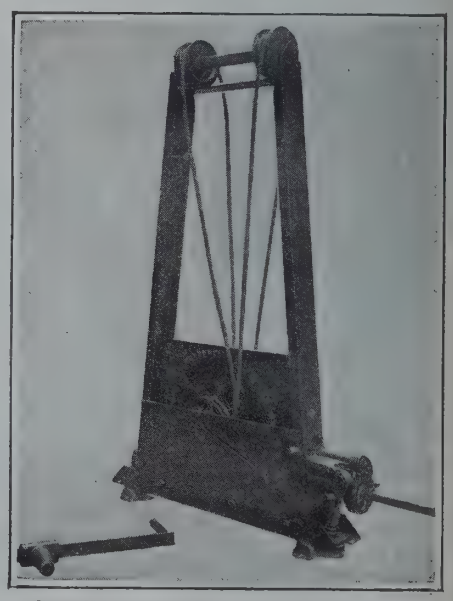
very easily maneuvered in congested spaces that are so often found around docks, factories or warehouses. It is easy to handle the heavily loaded trailers by maneuvering the tractor, in fact heavy loads can be moved much more easily than can be done with either horse-drawn vehicles or the conventional types of motor trucks of sufficient capacity to carry the loads.

## Hand Operated Hoist

A VERY simple and useful device that can be fitted to any motor truck is illustrated herewith. This is a hand-operated hoist that is used for tilting bodies of the dumping type. The hydraulic hoist as ordinarily used on motor trucks depends on the engine power for its operation and is somewhat too costly for installation on trucks that are used only intermittently for dumping purposes.

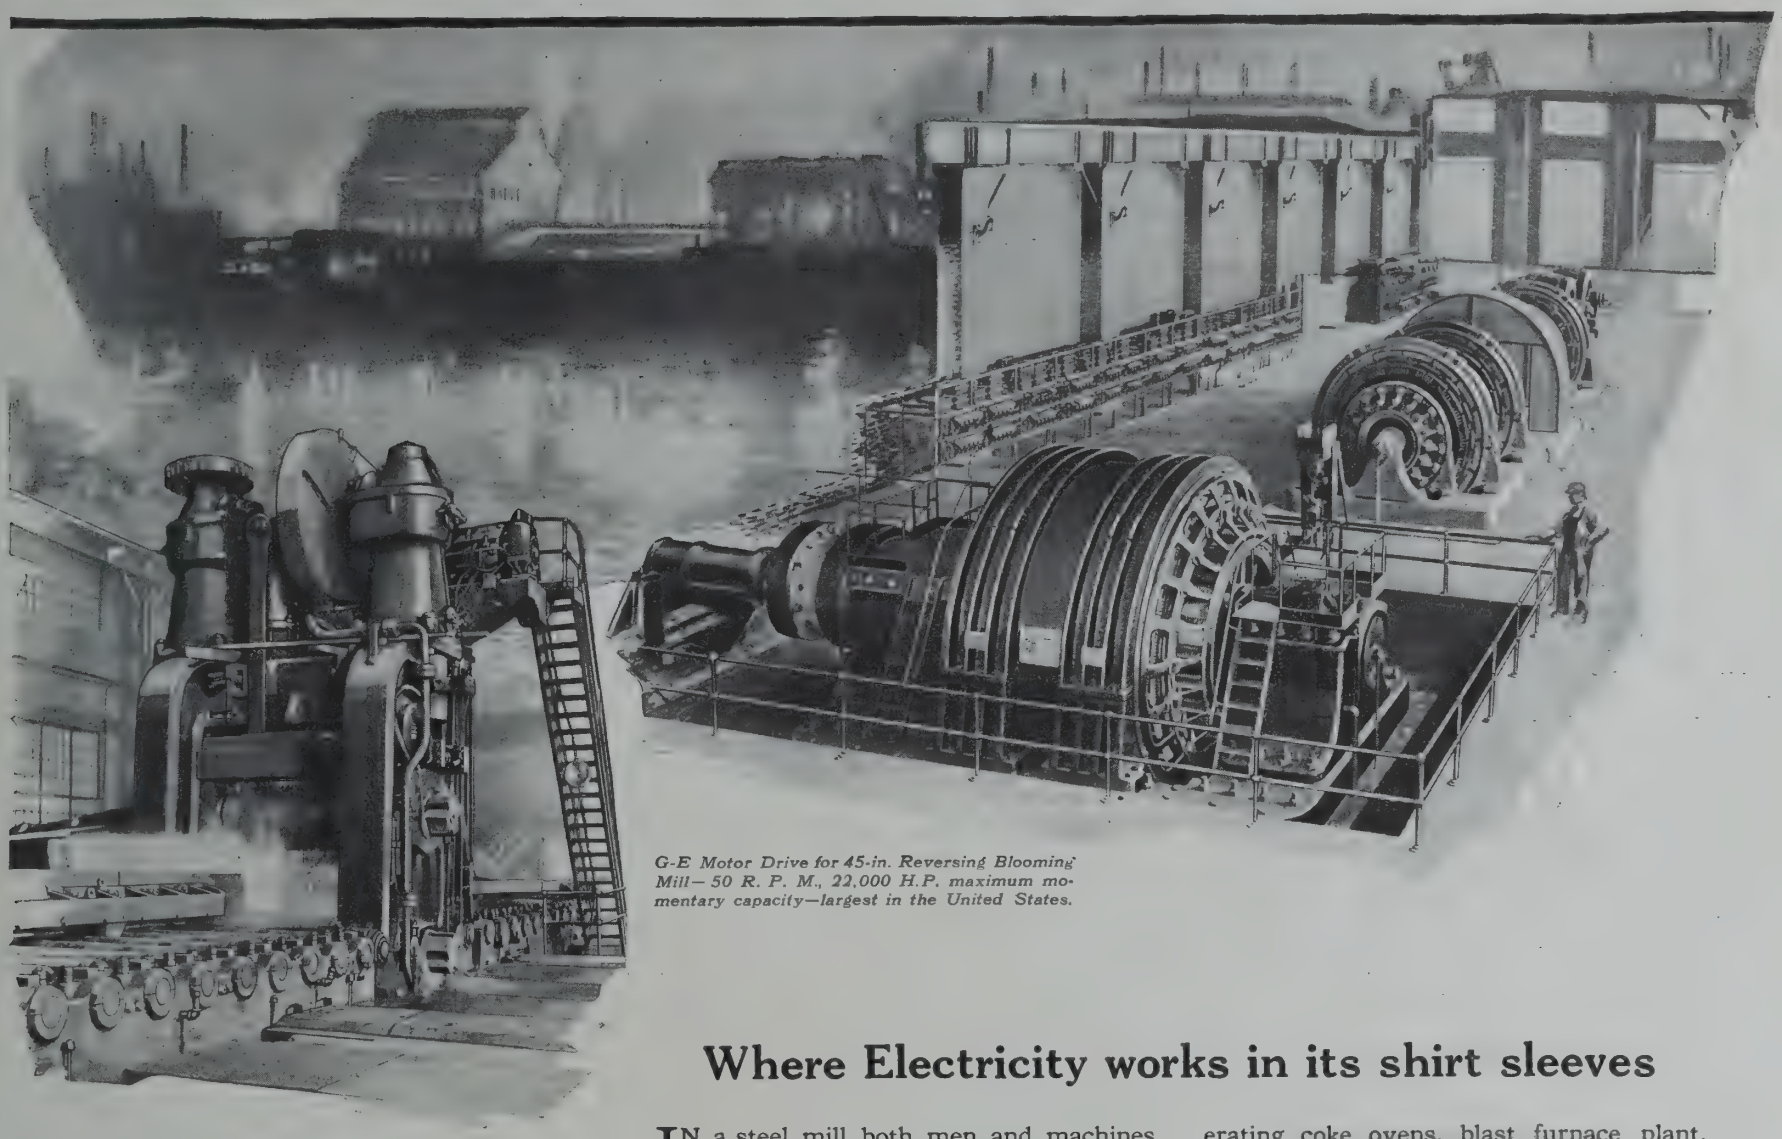
The hand-operated hoist may be obtained as a complete unit and is readily installed on any motor truck chassis as indicated. It is a substantial affair of structural-steel channel-section members and plates which completely enclose the actuating gearing. It is provided with pads at the base by which it may be securely attached to the motor-truck chassis by means of special U-bolts which encircle the pads and the motor car frame. The body and lifting cables are attached to arms which are furnished with the device and which are bolted to the front of the body. The body is hinged on the rear end and is provided with a hinged tail gate which may be controlled from the front end of the body by a suitable lever and rod connection.

A feature of interest is the form of crank provided, which is adjustable so as to secure various ratios of leverage, depending upon the weight to be lifted. The crank arm slides in a special member which is attached to the square end of the shaft operating the gearing. It is held in place in this socket by a pin, which can be set into any one of the holes provided along the length of the crank arm. An automatic ratchet is used so there is no possibility of the hand crank's reversing its direction of rotation due to the load lifted. The gearing is simple and provides a good leverage. The cables, which are attached to the lifting arms on the body, pass over sheave pulleys to a specially formed winding-drum of the winch mechanism on the base of the hoist.



**Details of hand-operated tilting hoist**

*The unlimited adaptability and easy control of electricity stimulates the development of great and small machines which mark the achievements of industrial progress*



*G-E Motor Drive for 45-in. Reversing Blooming Mill—50 R. P. M., 22,000 H.P. maximum momentary capacity—largest in the United States.*

## Where Electricity works in its shirt sleeves

IN a steel mill both men and machines must put forth the best that is in them—strength, endurance, speed, accuracy—all these are essential in either case. And the electrically driven machine has qualified for the hardest job of all.

As the white hot ingot of steel is carried on rolls back and forth under the blooming mill, it is literally squeezed into a bar, which grows longer as it grows thinner, and finally passes along to the bar mill. The blooming rolls must not fail, since production is so largely dependent upon their continuous performance—therefore G-E reversing motors are assigned to this strenuous task.

In other parts of a modern steel plant, G-E motors shoulder the heavy burdens just as faithfully—unloading coal and ore; operating coke ovens, blast furnace plant, open-hearth plant, sheared-plate mill, universal plate mill, and sheet and tin-plate mill. In one plant the installation of electric motors—the majority of which are G-E—totals 240,000 horse-power.

Where electric motors replace steam or hydraulic power, they occupy less space, are controlled from a central point, require in nearly every instance only one operator, and produce greater tonnage at a lower average cost—as proved by actual installations under various working conditions. The many advantages obtained through the use of G-E Motors and Control are at the disposal of all who invite the co-operation of the General Electric Company's steel mill specialists.

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

### Pertaining to Aeronautics

AIRPLANE.—H. C. NEAL, c/o H. T. Green, Philadelphia, Miss. An object of the invention is to provide an airplane embodying a construction whereby the airplane acts as a parachute in the event that the engine stops, so that the aviator may safely land on the ground. A further object is to provide mechanism capable of adjustment and operation while the machine is in motion to enable the airplane to remain in substantially one position to facilitate observations, or to remain vertical or in its normal position, when standing on the ground, and while in motion.

### Electrical Devices

ELECTRIC MOTOR.—L. FOOTE, Paraiso, Canal Zone, Panama. This invention has for its specific objects the provision of a field structure in which two rings or cylinders of the same diameter are arranged and a common axis, there being spaced teeth on the meeting edges of the rings, all the teeth of one ring being of one polarity and those of the other of opposite polarity, and the rings are so arranged that the pole teeth of one ring extend into the interpolar spaces of the other ring, whereby a plurality of closely arranged alternate poles are produced.

ARC-CURRENT REGULATOR.—J. A. HOLIFIELD, 1300 Church St., Mobile, Ala. The invention has for its object to maintain a substantially constant current within the limits of voltage desired for the arc in question. The invention is of special value in the arc of electrical welding as it is adapted to maintain constant current in the arcing circuit at all times without the presence of dead resistances and will function in an ideal manner to make a weld without burning places, globules or pitting.

### Of Interest to Farmers

AUXILIARY FLOOR FOR THRESHING MACHINES.—G. B. LUNDY, Niagara Falls South, Ontario, Canada. The invention has for its object to provide means for catching the falling grain from the feeder of the thresher, and wherein means is provided in connection with the said means for permitting the contents of the first sheet to be emptied into a particularly closed receptacle for convenience in dumping the same.

### Of General Interest

COMBINED BATHTUB AND DRESSER FOR BABIES.—E. L. NICKELS, 1243 W. Center St., Rochester, Minn. The invention has for its object to provide a device of the character specified; especially adapted for the use of babies, wherein the bathtub is built in the dresser, which is provided with a sliding top for covering the bath, capable of being slipped aside to provide a supporting surface for the baby after it has been bathed; the dresser also being provided with means for holding supplies.

SAFETY CATCH FOR BROOCHES. — B. BOCCACINI, c/o Tiffany & Co., 5th Ave. and 37th St., New York, N. Y. This invention relates to articles of jewelry or the like, and has particular reference to safety catches for coöperation with the pin portion of brooches, breast pins or emblems to prevent the accidental or unauthorized opening of the pin from its holding catch. More especially the device comprises a pedestal or frame made of any suitable quality of material such as sheet-metal and so stamped and folded as to provide not only a seat for the pin but also a space between the seat in which is pivotally mounted the keeper.

COOKING UTENSIL.—L. ARMBRUSTER, 510 W. 134th St., New York, N. Y. This invention relates to a cooking utensil; the aim is to provide a device wherein fluids such as milk may be brought to a temperature just below boiling without any danger of the same overflowing the side walls of the utensil, or scorching, as is now the case.

SUPPORTING LEG FOR WASHTUBS.—T. S. CASNER, 768 Kensington Ave., Plainfield, N. J. The invention particularly relates to a detachable leg for supporting a tub in elevated position. The object is to provide a detachable tub leg of simple and efficient construction, having means associated therewith for rigidly gripping and supporting the tub, which is adjustable to accommodate tubs of various heights.

WRIST WATCH HOLDER. — E EISENDECHER, Ultramares Corp., 280 Broadway, New York, N. Y. An object of the invention is to provide a device, which when the wrist watch is in position thereon, will have the appearance of a clock, or for display purposes. A further object is to provide a device which provides an elevated mounting for a wrist watch and bracelet or strap, and a centering recess to hold the watch in proper position.

REINFORCED CONCRETE FLOOR CONSTRUCTION.—D. J. FLYNN, 190 George St., New Brunswick, N. J. The object of the invention is to provide a reinforced concrete floor construction, reinforced longitudinally and transversely to render the floor exceedingly durable. Another object is to provide a floor with voids thereby making the floor exceedingly light. A further object is to permit of conveniently and quickly forming the floor without requiring highly skilled labor.

LUMINOUS THERMOMETER.—G. P. PITKIN, Bergenfield, N. J. The invention has for an object to provide a thermometer which can easily be read in the dark. A further object is to provide an attachment which can be placed on any ordinary thermometer tube and which will disclose the position of the expansible column in the dark as well as in the light.

ALLOY.—F. MILLIKEN, 55 John St., New York, N. Y. This invention has been granted two patents on alloys formed from copper, nickel, iron and zinc, under the influence of chromium or tungsten. The objects of the inventions are to provide an alloy characterized by having a high acid resisting quality, an increased density, an exceedingly close and fine grain, great tensile strength, increased elasticity and electrical resistance. The alloys consist of copper 50 to 60 per cent, nickel 26 to 34 per cent, iron 4 to 8 per cent, zinc 7 to 11 per cent, and .25 to 5 per cent of tungsten or chromium.

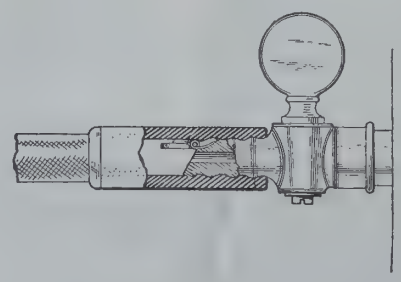
### Hardware and Tools

ATTACHMENT FOR WRENCHES.—L. A. BANTA, A.A.F.C., 36, Fellows, Cal. An object of the invention is to provide an attachment tool for socket wrenches which may be used in connection with socket wrenches for expediting the removal of cap screw bolts. It is a purpose to provide a tool of this character which will find a broad range of convenient uses in and around automobiles during the assembly and disassembly of the parts, and in other mechanical operations.

WINDOW LOCK.—R. BELLINGER, 226 E. Main St., Chicopee Falls, Mass. This invention relates to window locks; its general purpose is to provide a device which will lock a window in closed position or in any one of several open positions so as to secure ventilation at the top or bottom of the window or both. It is also a purpose to provide a lock when in locking position prevents rattling of the window.

### Heating and Lighting

SAFETY GAS COCK.—B. J. DIEHL, Dry Harbor Road and Cooper Ave., Glendale, L. I., N. Y. The invention aims to provide a device wherein the accidental displacement of the conventional rubber tube from the end of



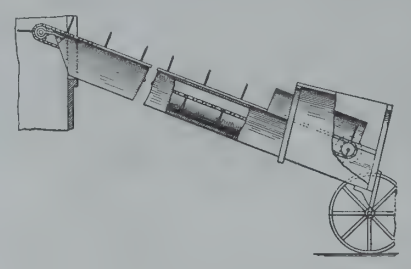
A SIDE VIEW PARTLY IN SECTION, OF A COCK WITH THE SECONDARY VALVE IN OPEN POSITION, AND MOUTHPIECE OF A RUBBER TUBE APPLIED

the gas-cock will result in the automatic shutting off of the flow of fluid. A further object is to provide a secondary valve for the nozzle in addition to the conventional turn valve, the secondary valve automatically cutting off the gas, should the tube be accidentally pulled off.

HEATED AIR SUPPLY APPARATUS FOR CLOTH DRIERS.—F. F. MCIVER, JR., Mandel McIver Co., 1805 1st Ave., New York, N. Y. Among the principal objects of the invention are, to avoid the necessity of providing a vertical support for cloth, to rest the supply of cloth in position for feeding the same to the drier, to prevent creasing the cloth while waiting to be dried, to economically heat air for supplying the drier and control the heater, and to avoid transmission of heat from the pipe supplying heated air to the casing thereof, forming a support for the cloth preliminary to drying.

### Machines and Mechanical Devices

GRAIN ELEVATOR.—J. B. MAJERUS, Bellechester, Minn. This patentee has produced a simple elevator of practical utility. It has running wheels at the rear and is adapted to be attached to any vehicle in transporting it from one place to another. When hauled to a barn or the like and positioned its trunk is inclined and the wheels removed for opera-



A SIDE ELEVATION, PARTS BEING BROKEN AWAY AND OTHERS IN SECTION

tion. The elevator is readily adapted to be given an angular position to suit the point of delivery. The grain is elevated by an endless belt with simple drive gear. A hopper is included into which the grain is shoveled or dumped.

APPARATUS FOR ICE MAKING AND REFRIGERATING PURPOSES.—C. DELAYGUE, address A. Monteilhet, 90 Blvd., Richard Lenoir, Paris, France. This invention relates to an apparatus for ice making, and mechanism is provided for evaporating in a closed vessel, by heat or other suitable means, a liquid in which are dissolved easily vaporizable substances, having a great affinity for the liquid, and in providing means for recovering and condensing the vapors in a second closed vessel constituting a refrigerator, and in finally producing in the said refrigerator the revaporization of the condensed products by contact with the substance to be cooled or frozen.

MACHINE OILER.—J. M. BUKACEK, Clarkson, Neb. This invention has for its object to provide an oiler adapted for use with machinery of any character, which may be made to positively deliver oil when desired, whatever the position of the oiler. The arrangement is such that when the handle is pressed toward the can a plunger is moved downwardly, thus forcing out the oil through the spout.

### Medical Devices

COMBINATION TRACTOR AND REPELLER.—P. C. JUHL, Princes Bay, S. I., N. Y. The invention relates to obstetrical instruments; its object is to provide a combination tractor and repeller more especially designed for use by veterinary surgeons on cows, horses, and other animals with a view to adjust abnormal position of a fetus. Another object is to enable a veterinary surgeon to readily apply and manipulate the instrument.

### Musical Devices

NEEDLE.—C. A. PORT, Windsor Mo. The invention has for its object to provide means for firmly holding a filament of wire against movement away from the record and for connecting the said filament to the needle holder of a talking machine in such manner that the wire may be used to engage the record.

### Prime Movers and Their Accessories

SUPERHEATER FOR INTERNAL COMBUSTION ENGINES.—H. A. LACERADA, 3258 Hudson Bldg., Jersey City, N. J. The object of the invention is to provide a superheater for internal combustion engines such as are used in automobiles, marine and aerial vessels and the like, and arranged to generate superheated steam and to supply the same to the explosive mixture to increase the efficiency thereof and prevent the formation of carbon and other deposits in the cylinder. Another object is to dispense with the usual overflow pipe in the radiator.

SPARK PLUG HOLDER.—C. E. WAKE, 509 E. Sumach St., Walla Walla, Wash. The invention has for its object to provide a device for conveniently handling spark plugs without danger or discomfort from the hot plugs, and without the necessity of soiling the hands. A further object is to provide a spark plug holder which grips the plug but which can be easily released therefrom by pressing the handle members toward each other.

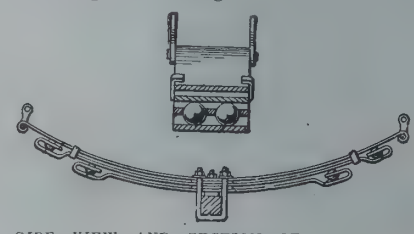
### Railways and Their Accessories

RAIL PLATE AND FASTENER. — J. G. HILL, 512 Railroad Exchange Bldg., Kansas City, Mo. The invention relates generally to track securing devices, and more particularly to a simple, economical rail plate and fastener, the object being the provision of an effective device which may be used in practice with great advantage, in order to prevent overturning and creeping of rails as well as an arrangement whereby the rails may be readily released and removed when substitution becomes necessary.

### Pertaining to Vehicles

TIRE FOR MOTOR VEHICLE.—J. J. DANA, 17 W. Anderson St., Savannah, Ga. The object of this invention is to provide a tire having the resiliency of a pneumatic tire, without the liability of the same to puncture and blowouts, and wherein the resiliency of the tire may be varied to suit conditions. The tire is characterized by a series of housing plates which permit of a limited hinge motion, and a tread ring of rubber or the like on its outer face.

BALL BEARING SPRING.—G. A. SAVILLE, JR., 619 So. 11th St., Lincoln, Neb. The invention has for its object to provide a spring especially adapted for motor vehicles, but suitable for vehicles of any character, wherein ball bearings are arranged between the leaves



A SIDE VIEW AND SECTION OF THE SPRING CONSTRUCTION

of the spring at the ends of the said leaves, a bearing being arranged at each end of the leaves between the said end and the adjacent leaf for making the spring more flexible, reducing wear and increasing resiliency.

LICENSE TAG HOLDER.—T. J. CHAPPELL, Castleton, N. D. This invention has for its object to provide a simple, inexpensive device of the character specified which may be detachably connected with the hood of a motor vehicle, and with the license tag in a manner to be easily removed when desired, and wherein the holder has means for preventing swinging of the crank.

VULCANIZER.—E. D. HOSTLER, Tipton, Iowa. The invention relates more particularly to a mandrel for use in vulcanizing the ends of the inner tubes for automobile tires and the like, an object being to provide a device which permits the tube ends to be vulcanized on the outside thereof, thus permitting a ready manipulation of the tube so as to insure a proper positioning of the parts and also permit a full observation of the vulcanizing process.

### Designs

DESIGN FOR AN INHALER.—E. H. METCALF, Marlboro, N. H.

DESIGN FOR A BRIDGE PLATE FOR WATCH MOVEMENTS.—C. F. COLOMB, 30 W. 36th St., New York, N. Y.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

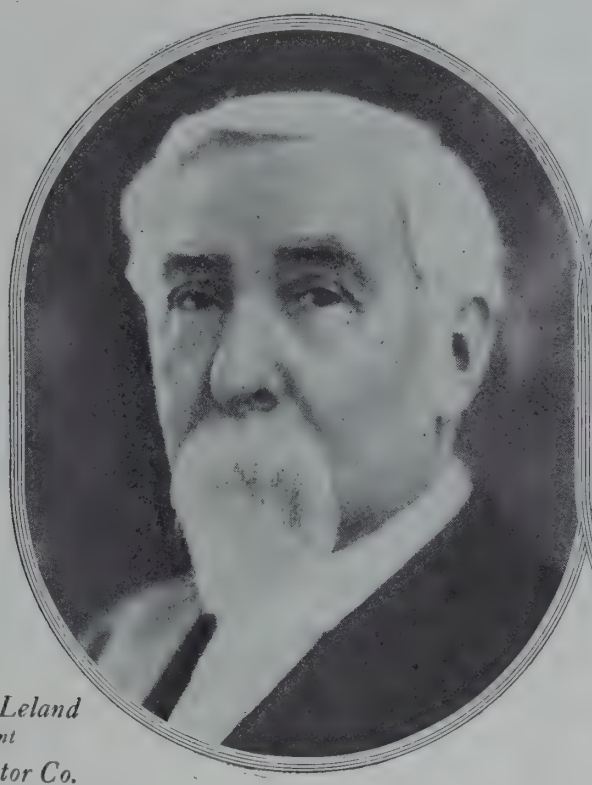
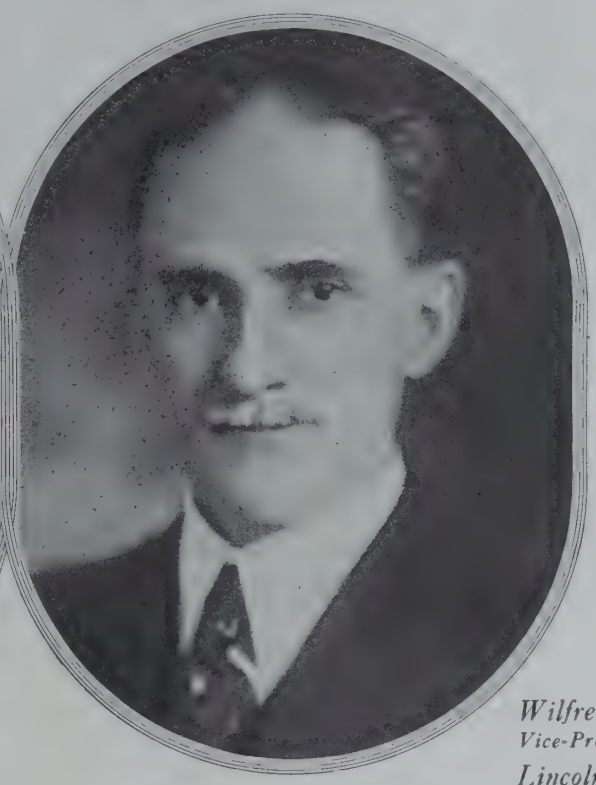
# The Leland Contributions to Motordom

*Pioneers of the Industry, Henry M. Leland and Wilfred C. Leland, Organizers of the Lincoln Motor Company have been outstanding factors in Motor Car Development*



*Henry M. Leland*
*President*
*Lincoln Motor Co.*



*Wilfred C. Leland*
*Vice-Pres. & Gen'l Mgr.*
*Lincoln Motor Co.*

Looking back over the progress of a generation, it would be difficult to recall anything which has contributed to the welfare of civilization and to the healthful enjoyment of mankind more than has the motor car.

Recalling the achievements which have marked the beginnings of various epoch-making periods in motordom, where do you find examples more impressive or which have been more far-reaching in their influence than those inaugurated by the Lelands during the past eighteen years, with the co-operation of thousands of skilled and loyal associates;

—the first practical, enduring car, made in large numbers;

—the thorough standardization and interchangeability of parts;

—close and fine workmanship, expressed by accuracy measured in thousandths of an inch and even in fractions of a thousandth;

—the initial adoption in motor car workmanship of the Johanssen gauges, accurate to the one-hundred-thousandth part of an inch—instruments which have helped to make possible such wonderful precision;

—scientific practices and methods in manufacture, which made possible a car of highest quality, at a price then far below prevailing figures for a comparable product:

—the electrical system of starting—lighting—ignition;

—the thermal regulation of the water circulating system;

—the V-type, *high-speed, high-efficiency* engine, the influence of which upon the industry has been almost immeasurable?

As a crowning achievement, one has but to observe their record both as to quantity and quality of Liberty aircraft motors.

And to the Lelands is due a multitude of other things—in manufacturing practices and in motor car refinement—some seeming small in themselves perhaps, but almost limitless in their influence and incalculable in their value in making motor cars the wonderful mechanisms they are today.

The Lelands have been favored by an additional advantage in that usually they have been afforded first opportunity to consider new devices developed by independent and unaffiliated genius.

This because it was realized that the seal of Leland approval spelled success in motordom, and that generally it meant ultimate adoption by other good-car makers.

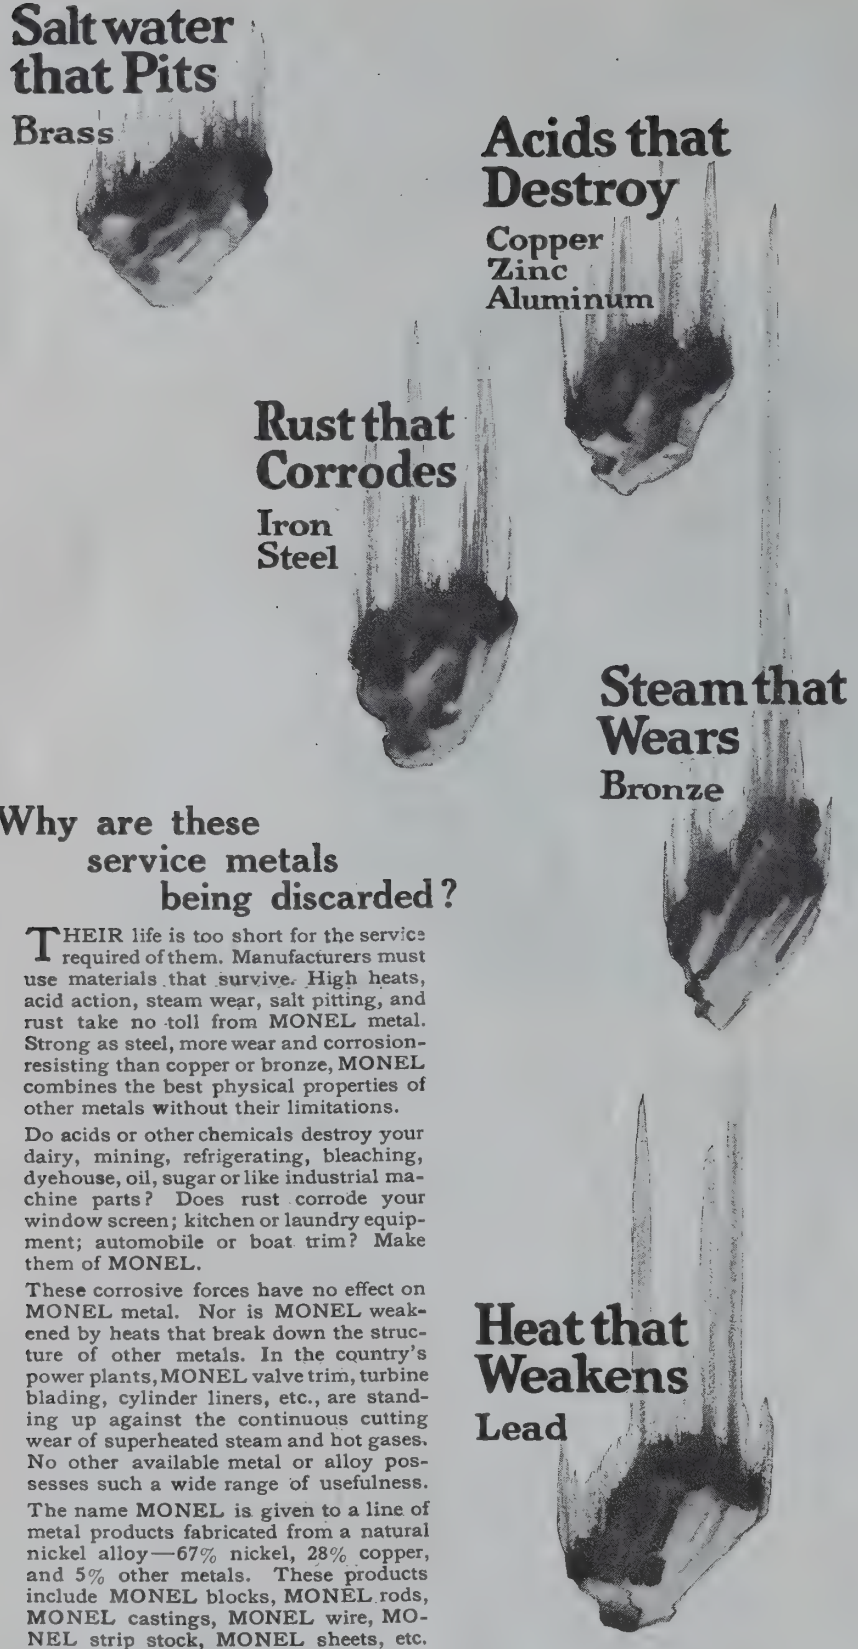
Entering the industry practically at its inception, the Lelands soon became recognized as possessing two predominant traits: first, to achieve and to surpass—for the sheer satisfaction derived from those accomplishments: second, to strive unceasingly for the betterment of motor cars, in everything that betterment signifies—to make them more trustworthy, to make them more enduring, to make them a source of greater comfort, to provide greater conveniences, to make their care and their operation unirksome—in short, to make their possession more desirable from every viewpoint.

Is it not logical, therefore, that men recognized as foremost exponents of advanced ideas, will guard and preserve that enviable distinction?

In the light of past accomplishments, could anything be more logical than that the new Leland-built car will embody refinements naturally to be expected of men occupying positions in the forefront of advancement—positions to which the serious-minded in the industry are wont to aspire?

And in the light of past accomplishments, could anything be more logical than that the new Leland-built car will uphold Leland traditions: and that it will evidence, more impressively than ever before, Leland determination and Leland ability to achieve—and to surpass?

LINCOLN MOTOR COMPANY DETROIT, MICHIGAN



## Why are these service metals being discarded?

THEIR life is too short for the service required of them. Manufacturers must use materials that survive. High heats, acid action, steam wear, salt pitting, and rust take no toll from MONEL metal. Strong as steel, more wear and corrosion-resisting than copper or bronze, MONEL combines the best physical properties of other metals without their limitations.

Do acids or other chemicals destroy your dairy, mining, refrigerating, bleaching, dyehouse, oil, sugar or like industrial machine parts? Does rust corrode your window screen; kitchen or laundry equipment; automobile or boat trim? Make them of MONEL.

These corrosive forces have no effect on MONEL metal. Nor is MONEL weakened by heats that break down the structure of other metals. In the country's power plants, MONEL valve trim, turbine blading, cylinder liners, etc., are standing up against the continuous cutting wear of superheated steam and hot gases. No other available metal or alloy possesses such a wide range of usefulness.

The name MONEL is given to a line of metal products fabricated from a natural nickel alloy—67% nickel, 28% copper, and 5% other metals. These products include MONEL blocks, MONEL rods, MONEL castings, MONEL wire, MONEL strip stock, MONEL sheets, etc. MONEL is a product of The International Nickel Company, producers of Inco Nickel—the standard for alloy steels.

## Turning the Wheels of a Century Hence—III

(*Continued from page 60*)

horse-power. We want to use it. We want to keep it for our own, but to have it developed for us by individuals or corporations which know how, and which, naturally, want to be paid for their knowledge. Let us, therefore, enact such legislation as will foster water-power development; let us repeal such legislation as interferes with it. Let us take the red tape off the water wheel and let it turn and let us do it now—now, when coal is expensive and transportation vital and prices high and inexpensive power badly needed.

To do this we need a water-power bill which will help develop water power with private capital; charge the government with a certain amount of water-power development; develop the power now running to waste in national forest and other government-owned or reserved lands; conserve the rights and interests of the nation; make available our power as a measure of national preparedness for war; make our power sites revert to the nation, no matter how developed or what private capital is interested, in a sufficient period of years; and provide for an accurate, elaborate and complete report upon the available water power, natural and undeveloped, the possibilities of power to be developed by storage, and a continuing census of power statistics which will be at all times available to interested capital and to the government.

To this end, every power user should interest himself in the bill now before Congress, and use whatever influence he possesses to its passage, and what is more important, its speedy passage. The water wheel is as old as civilization. The United States has untold wealth running to waste every second of the day in undeveloped power. The high cost of living is partly a high cost of labor and labor is but another word for power. That we, supposedly the most progressive of nations, should have a great power source but partly developed, when we might have millions of horse-power turning our wheels without depleting our already exploited coal and oil fuel, is an economic crime.

In the last analysis, governments do what the people under those governments demand. This government will develop or cause to be developed the water power nod wasted when, and not until the people of the United States demand it. That demand is voiced only by individuals and associations. It is voiced by letter, word of mouth, newspaper publicity and telegram. It can be made effective only when it is large in volume, and large volume of voice comes from individuals, of which number you, the reader of these pages, are presumably one.

Power affects us all. Power is the root of our civilization. Power makes us great, and as it is cheap and efficient so is the process of living inexpensive and happy. To waste human power is to waste life itself; to waste national power is to drain away a nation's life for nothing.

What will *you* do to conserve and develop the wasted power resources of your country?

## Fighting Waves with Compressed Air

(*Continued from page 61*)

there were more safe harbors. Under the protection of compressed air, piers can be erected and maintained in any location, no matter how exposed, and vessels can ride there and be unloaded, no matter what weather conditions prevail.

Nor are these all of the uses of such a protecting system. It can be used to build up beaches, or to make them safe for bathers, and furthermore it does not destroy the appearance of the beach or make it unsafe and unsightly, as groins do.

LEGAL NOTICES

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

**SCIENTIFIC AMERICAN**
contains Patent Office Notes. Decisions of interest to inventors—and particulars of recently patented inventions.

But the greatest service of all, perhaps, is the protection that can be given to boats and workmen in exposed places. The erection of breakwaters, piers, lighthouses and dams may be continued steadily, no matter how the white caps may toss. Think what such a system as this would have meant to old Captain Smeaton as he battled to make a lighthouse stand through the stress and storm on the wave-washed rocks at the entrance to Plymouth harbor. With the compressed air machinery working steadily, ample protection is given the builders.

### What About Our Forests?

(*Continued from page 62*)

the New England states is still forest land, in spite of heavy cutting and dense population. But careless woodsmen have done almost irreparable damage there. A recent scientific investigation revealed the fact that about half of all the fir in this territory, as well as in eastern Canada, is dead or dying, from insect pests and disease.

The reason assigned for this is that when wood was plentiful the woodsman scorned the fir tree, or balsam as it is called in Canada. The firs were left standing and other trees cut out around them. For a while the firs grew luxuriantly in their isolation but through this very fact has come their downfall. Insects and diseases to which the fir is peculiarly subject spread rapidly because there were no other trees to halt them and the result is that nearly all of this valuable lumber will be lost.

A relative of this tree, the Douglas fir of the West, now is one of our principal sources of lumber supply. The yearly harvest in the state of Washington alone now is about 6,000,000,000 board feet and in Oregon another 1,500,000,000 feet.

There are still large forests in the East outside of New England. State Forester Gaskill of New Jersey recently pointed out that there are 2,000,000 acres of woodland in his state and that the possibilities in these are now almost wholly neglected. New Jersey, he says, has a favorable climate for the growing of trees, much land unfit or ill fitted for agriculture, and close at hand markets for all the lumber that can be produced. Even on the so-called pine barrens in the southeastern part of the state, the growth of trees is rapid. Trees need little more care than protection from fire; and fires, even in New Jersey, rival the lumberman in destructiveness.

Some few states have already adopted forest policies but at present we are planting only one tree for every 10,000 that are cut down. There is nothing mysterious in successful forestry. Most European countries have followed the practise for many years of planting a tree for every one cut down. Only mature trees are allowed to be cut so that the forests are perpetual. It is true that much lumber is imported from this country but our own supplies have reached the point where we can continue our wasteful methods only at the greatest peril to the nation's future.

Europe's methods of reforesting are perhaps too costly for immediate adoption here but adoption of a real national program would undoubtedly bring the country's production of timber up to our needs and would prevent needless waste.

For instance it has been found that the best policy in the Douglas fir lands of the Northwest is to cut off the timber clean, perhaps leaving an occasional seeding tree. Then at the right season the land is burned over to destroy pests. This treatment results in a good stand of young trees and thereafter they need only protection from fire to produce 1,259 board feet of timber per acre each year while the trees are maturing. This involves very little expense and labor, aside from supervision and fire protection, and provides a paying crop on land which might otherwise have become a barren waste.

"They're good blades, those Starrett blades. Every tooth in 'em is made to cut fast and long."

Starrett Hack Saws ARE good hack saws. They've got to be to live up to the reputation of Starrett Tools. But speaking of teeth—how many of the teeth in the saws you're using now, no matter whose make it is, are cutting?

Did you ever stop to think that the length of the blade you used had a direct bearing on the life and efficiency of the saw?

The longer the stroke, the more teeth there are used. Do you follow the idea?

Get a copy of The Starrett Hack Saw Chart and the Starrett Book, "Hack Saws and Their Use"—they'll help you cut your cutting costs.

Both are free. Ask for Chart "B."

Use Starrett Hack Saws

### Hack Saws and Lubricants

The unseen element in a hack saw blade is the quality given to it by heat treatment and quenching. Heat treatment may ruin the best of steel or it may, when properly done, give to each blade the exact quality that best suits it for the conditions under which it is to be used. Naturally the "temper" of a hack saw must vary with the material to be cut. No matter what temper the blade may have, however, it is an element that must be taken into account. Drawing the temper of a hack saw, by cutting without the use of lubricant, is a frequent cause of the failure of blades.

In this connection, the following excerpt from HACK SAWS AND THEIR USE, a new book just issued by The L. S. Starrett Company, is of interest to hack saw users:

"Compound should always be used except when cutting iron castings, as it greatly increases the output, doubling it at least. Either water or compound may be used, but never oil.

"Whatever the liquid employed, its purpose is not so much to lubricate the work as to cool the blade, since the high speed of cutting generates considerable heat which draws its temper. The work should be kept flooded, for a scanty flow of compound simply increases the likelihood of chips sticking in the cut and breaking the saw.

"The importance of lubrication, in its effect on the time per cut and the number of cuts per blade, is clearly shown in a test made with three identical saws, used on the same bar of metal.

"A flexible hack saw was chosen because, in the test, the abuse of the blade was intentional in the first two instances, and had an all-hard saw been selected, the probabilities are that it would have failed even sooner, especially as the strokes per minute, when cutting dry, were excessive.

"All these blades were started under the same pressure of 24 pounds. No. 1 saw was run without lubrication at 65 strokes per minute, an excess of 15 strokes over the recommended speed, and failed when partly through the fifth cut. Blade No. 2 was run 'dry' at 100 strokes per minute, or double the proper speed, and failed when about half way through the third cut. No. 3, *used with compound* at 100 strokes per minute, completed 50 cuts at a fair average speed, and was cutting at its apparent maximum efficiency under 56 pounds of pressure, when the test was discontinued.

"Just to what extent the excessive speed employed with the blades that were run 'dry' contributed to their early failure is a trifle uncertain, but its influence is none the less unmistakable. It may be said in this connection that, when cutting dry, an excess speed of as little as ten strokes per minute will ruin a saw by drawing its temper."

From HACK SAWS AND THEIR USE, published by The L. S. Starrett Company, Athol, Mass., for free distribution.

RUSCO RUSCO RUSCO

If immediate steps are taken to care for these mighty forests of the Northwest the nation will be insured a continual lumber supply. If we continue our present course it will be only a matter of a few years when these forests will be in the position now occupied by the southern yellow pine forests. It is estimated these southern forests will be gone in ten years and that within seven years 3,000 manufacturing plants in the South will be forced out of business because of this fact.

To quote from a bulletin of the American Forestry Association:

"Within fifty years our present timber shortage will have become a blighting timber famine.

"Forests can be protected from fire, regrowth can be encouraged, conservative cutting can be practised, restoration can be accomplished—but it takes from fifty to a hundred years to mature a timber crop.

"Forest devastation must be stopped, lands now in forest must be kept continuously productive, forest lands now devastated and idle must be put to work."

It is a timely warning. The man who wishes to help need not go to the Northwest to do it. There are woodlands and trees in every community that need to be recognized as a valuable asset and given protection accordingly.

### "Resolute" Defends the Cup

(*Continued from page 64*)

that "Resolute" makes 9.25 knots over the actual distance sailed to windward, and 11 knots to leeward and that "Shamrock" saves 4 minutes of her handicap up the wind and two minutes down wind. To do this she would have to make about 9.6 knots to windward and 11.3 knots to leeward.

The assumed speeds are high, especially to windward; but they will serve the purpose of showing the task which "Shamrock IV" will have to perform if she is to save six minutes over the fastest boat for her length that we have ever turned out on this side of the water.

"Shamrock" has an excess of 20 per cent of sail area; but she labors under the disadvantage of a great excess of wetted surface. Moreover, the American boat has an easier form to drive, especially in reaching and running. On the other hand, looking at the problem broadly, the average yachtsman will tell you that as between sail area and time, he would choose the sail area.

### The Man Behind Our Daily Bread

(*Continued from page 66*)

weighing buckets and quickly returned to the bags after passing inspection.

The scales used in weighing are of the balance type. The grain is poured from the testing pan into a stationary funnel which is closed at the small end with a slide. When this slide is opened the grain pours down into a brass bucket which has a capacity of an even quart when leveled off. The bucket of grain is then attached to the scales, the reading bar of which has arbitrary figures showing what the grain will weigh a measured bushel. The inspectors must ascertain the weight of a measured bushel of grain inspected by them and report the same in their records, because weight is an important factor in arriving at a final decision on the quality of the grain.

After the grain is weighed it is carefully examined to determine its grade, and the inspector marks on a card with a printed form the grade number and kind of grain with notations and weights. This card is enclosed in the bag with the grain, and the clerical force makes a detailed record which is kept on file so that if a shipper at any time requires an inspection certificate it is issued upon request. The clerical department issues two certificates on every car inspected, which go to the receiver of the grain in Chicago, and he, in turn, sends one to the shipper and one to the buyer of the grain.

IN these days of mounting costs, the fuel problem in power production is of vital interest. Bessemer Oil Engines operate on any low-grade fuel oil, thus minimizing operating expense to such an extent that this one reason alone makes a Bessemer imperative. But there are many other reasons. Write. 15 to 180 H. P.

**THE BESSEMER GAS ENGINE CO.**
14 York Street Grove City, Pa.

# BESSEMER OIL ENGINES

These certificates are issued on the day of inspection for the convenience of the trade in general. Half of the actual sample of grain inspected is retained in the offices of the Inspection Department and half is placed in a paper bag and sent to the grain commission merchant to whom the grain was consigned. The commission man uses this for his selling sample on the exchange floor of the Board of Trade.

In addition to the tests given other grain, corn is put through the moisture-tester. This method was not universally employed until in recent years, and its importance was augmented by the standard system of grading corn authorized by the government a few years ago. The amount of moisture contained in corn is a matter of great concern to the man handling it, and grain which in all other respects appears excellent has to be graded low when it is filled with water.

Corn containing much moisture does not keep as well as when dry, as it is apt to heat, sour or mold. Elevator people do not like to store it for this reason, and in warm weather it can be shipped only at considerable risk. The various industries engaged in the manufacture of corn products also prefer dry corn for economical reasons. The weather at the time the corn is harvested is a big factor in determining the amount of moisture it will contain, but corn absorbs moisture so readily that care must be used in handling it at all times.

The apparatus used for determining the amount of moisture in corn is simple enough in its operation yet truly wonderful in its achievement. Its principle is to boil the water out of the corn and condense it. This is accomplished by placing the corn in a glass container or distillation flask with a certain amount of mineral engine oil. These flasks are globular in shape with a neck at the top and a long narrow glass tube running from near the bottom of the neck. The flasks have a capacity of approximately 1,000 cubic centimeters, and are of the best grade of resistant glass and well annealed in order to withstand sudden changes in temperature without breaking.

After the bulk sample is properly mixed, the desired quantity for the moisture test is carefully weighed and emptied into the distillation flask with the necessary quantity of oil. In the case of corn, 100 grams by weight of the grain is used to 150 cubic centimeters of oil; with oats, 50 grams by weight to 150 cubic centimeters of oil. As soon as the grain and oil are placed in the distillation flask they are thoroughly mixed by shaking them. A thermometer, with rubber stopper attached, is then placed in the neck of the flask and the grain and oil heated to a temperature of 190 degrees Centigrade, after which the flame is turned off and the mixture allowed to cool about twenty-five degrees. The moisture in the grain turns to steam during this process and the only means of escape for the steam is through the tube of the flask. This tube is connected by a rubber stopper and runs through a tank of cold water. Thus the steam from the grain is condensed as it passes through the cold water and drops into a graduate below. The reading of this graduate when the grain has cooled completes the test.

Corn that shows only 14 per cent moisture is graded No. 1. If it contains 15.5 per cent it is graded No. 2; if 17.5 per cent, No. 3; if 19.5 per cent, No. 4; if 21.5 per cent, No. 5; and if 23 per cent, No. 6. Should the moisture content exceed 23 per cent it is classed "sample grade." About half an hour is required to determine the moisture content in each sample.

In determining the grade of corn there are other things besides the moisture test to be taken into consideration. These are damaged kernels; foreign matter; corn that is hot, heat-damaged, fire-burnt, sour, musty, immature, blistered, or infested

# You and yours

## Should brush teeth in this new way

*All statements approved by high dental authorities*

Millions of teeth are now cleaned in a new way. You see them everywhere—glistening teeth.

They are pretty teeth, but there's a deeper reason for them. They are safer, cleaner. The cloudy and destructive film is every day combated.

You will use this method and have your family use it when you make this ten-day test.

### To end the film

The purpose is to fight film—that viscous film you feel. It is the teeth's chief enemy.

It is that film-coat which discolors. Film is the basis of tartar. It holds food substance which ferments and forms acid. It holds the acid in contact with the teeth to cause decay.

Millions of germs breed in it. They, with tartar, are the chief cause of pyorrhea. Thus most tooth troubles are now traced to film.

The film is clinging. It enters crevices and stays. The ordinary tooth paste does not dissolve it, so the tooth brush leaves much of it intact.

It dims the teeth, and month after month, between dental cleanings, it may do a ceaseless damage. That is why tooth troubles come despite the daily brushing.

### What dentists urge

Dental science, after years of searching, has found a way to combat film. Authorities have amply proved it by many careful tests.

It is now embodied in a dentifrice called Pepsodent—a scientific tooth paste. And leading dentists everywhere are urging its daily use.

## Sent to anyone who asks

A 10-Day Tube of Pepsodent is sent to anyone who asks, and millions have thus proved it. Every person owes himself that test.

Pepsodent is based on pepsin, the digestant of albumin. The film is albuminous matter. The object of Pepsodent is to dissolve it, then to day by day combat it.

But pepsin must be activated, and the usual agent is an acid harmful to the teeth. So this method long seemed barred. Now science has discovered a harmless activating method, and active pepsin can be every day applied.

Two other problems have been solved in Pepsodent. In three ways this tooth paste brings a new era in teeth cleaning.

Watch the results of a ten-day test. Read the reason for them, then judge for yourself what is best.

**Pepsodent** PAT. OFF. REG. U. S.

*The new-day dentifrice*

**A scientific film combatant, combined with two other newly recognized essentials. Now advised by leading dentists everywhere and supplied by druggists in large tubes.**

### Watch them whiten

**Send this coupon for a 10-day tube. Note how clean the teeth feel after using. Mark the absence of the viscous film. See how they whiten as the film coat disappears. Cut out the coupon now.**

*The Leading Authority* *Eighth Revised Edition*

**Electro-Deposition of Metals**

By Dr. GEORGE LANGBEIN and WILLIAM T. BRANNT

Since the publication of the first edition of this volume, it has had the distinction of being considered the foremost American book issued on the electro-deposition of metals.

The new eighth edition, just published, has been completely and carefully revised, considerably enlarged and entirely reset, and is so far superior to its predecessors as to assure its continued predominance. It is the master treatise on the subject and is practically an encyclopedia of the art. It contains everything any one wants to know about the plating and the finishing of metals and covers electro-plating, galvanizing, metal coloring, lacquering, electro-typing, galvanoplasty, etc.

It is a complete, authoritative and up-to-date work of instruction and reference and should be possessed by everyone connected in any way with the plating and polishing industry.

A descriptive circular and table of contents will be furnished on application.

with live weevil. "White corn" must be at least 98 per cent white, and "yellow corn" at least 95 per cent yellow. The grades of wheat are determined by the variety, winter or spring (which mean, respectively, wheat sown in the fall and spring), hard or soft, and by soundness, plumpness, dryness, sweetness, weight, and also its degree of cleanliness. Color likewise is an important factor in grading wheat. Rules for grading oats, rye and barley are largely the same as those applied to wheat.

## Preventing the Oxidation of Metals from Heat

THERE are numerous places in which the ordinary means of preventing metal from oxidizing are futile. The leading electrical manufacturers, for instance, have long recognized the need for better protection of the various heating elements from this type of destruction; for in some cases these elements are exposed to oxygen in the unusually active form of ozone, created by the electric current itself, and even when his complication is absent, the extreme temperatures to which heating elements may be raised must necessarily make the oxidation problem an acute one. Another instance of similar exposure is found in mechanical soot-blowers for boilers, which are subjected to hard and continuous service at boiler temperatures, in the presence of hot gases of all sorts, and under the additional stress of mechanical contact with quantities of soot. And these are but examples showing that the ordinary resistant metals are not always sufficiently resistant to oxidation under acute conditions.

Several years ago one of the large electric companies, in view of this state of affairs, instituted a research for the development of some process of treatment that would render metals more resistant to oxidation at high temperatures. At the present time the process has reached a stage where this company is using it regularly; it has been tried out in several other connections, notably that of soot-blowers already mentioned; and it seems so promising that a company has been formed for the sole purpose of commercializing it.

The process, to which the name "calorizing" has been applied, depends upon the high heat-resistance of aluminum oxide. The parts to be treated are packed in a retort with an alumina mixture and other chemicals whose identity is not for the present divulged; hydrogen gas is introduced into the retort; and the temperature is then brought gradually up to 1650 degrees Fahrenheit in the electric furnace. After holding the heat at this point for a proper time, the retort is allowed to cool slowly, the introduction of the hydrogen still continuing. When cold the treated parts are withdrawn and cleaned. It is then found that the alumina has penetrated the surface metal of the treated parts to a greater or less degree, depending upon the time through which the process is allowed to extend. A homogeneous protective alloy is thus formed with the surface metal, not unlike an amalgam. This alloy shell is strongly resistant to the oxidizing influence of heat, and at the same time no physical change is apparent in the calorized portion of the metal, with the exception of the mild anneal resulting from the heating in the furnace. In particular, there is not the slightest tendency of the protective shell to strip or otherwise to behave as anything other than an integral part with the metal beneath it.

Over $100,000 has bee nexpended in developing the proper character of furnaces, retorts, mixtures and handling, and the development of the calorizing process has been brought to a high point of efficient application. During the past two years thousands of parts have been calorized for many of the largest industries of the country and the plant has been visited by many eminent chemists and metallurgists, as well as by mechanical experts, who were interested in observing the process in operation and determining the results by first hand investigation. Their reports have been enthusiastic and they generally predicted a large use for calorizing among industries experiencing heat-oxidation problems.

Where high temperatures in combustion are employed, ranging up to 1800 degrees Fahrenheit, calorized metal is said to give most excellent results. The ideal temperatures for its use range from 1100 to 1750 degrees Fahrenheit, and at 1800 degrees the resistance to oxidation from heat very sliwly diminishes. Close-grained cast iron, black and wrought iron, steel, nickel, nickel-steel, brass, bronze and copper have been successfully calorized and a much longer life incorporated in their use in high temperatures. A large application is seen in relation to calorizing of annealing and carbonizing boxes, pyrometer protection-tubes, retorts, super-heaters, vaporizers, burner collars, pipe and tubing, and a multitude of other uses among many industries. Calorizing is not a preventive of atmospheric oxidation, or oxidation from moisture. It has wonderful resistance, however, to oxidation from heat, up to 1800 degrees Fahrenheit, and assures a much less frequent replacing of equipment or machine parts, with elimination of the considerable labor cost involved and loss of production resulting from laying-up of equipment.

## Ball Bearings in Steamship Engines

THE Swedish ball bearing manufacturers, after introducing successfully ball bearings in Swedish rolling stock, especially the Swedish State railways, are now entering new fields of experimentation, which have for their object the introduction of the ball-bearing principle in ship construction, especially in connection with propeller shafting. The problem completes the construction of a bearing able to withstand all axial pressure from the propeller and excluding all possibilities of hot box and kindred troubles. The successful ball bearing, it is claimed, must under the most trying conditions be able to withstand the axial pressure automatically and require little or no attentio hand must be of such simple and reliable construction that friction within the same is minimal and that the ship's movements may not influence disadvantageously the ball-bearing mechanism.

While ball bearings are used to a considerable extent in marine engineering, their application and their mounting have seen their highest development in Swedish shipyards. This is the contention of Swedish shipbuilders generally, but will doubtless meet challenge in the United States and Great Britain, where shipbuilding yards have not been slow to see the advantages offered by ball bearing.

## Invention in Flashlight Photography

IN the *Times'* report of a meeting at the Royal College of Science, a demonstration in flashlight photography was given by Mr. K. Hickman. A "snap" of the audience was taken and a photograph of the chairman. The plates were then given a rapid development, with a lightning wash; fixation in afixing solution which was effective in 30 seconds, an invention of the lecturer; a further washing for 2 minutes, in which time the hypo was removed by dilute permanganate; a bath for 2 minutes in formalin solution, after which the plate was rinsed, dried in a stream of hot air from a machine of the lecturer's design, and finally printed on a lantern plate. Within half an hour of the exposure, a lantern-slide photograph of the chairman was projected onto the screen. Mr. Hickman also dealt with the screen-plate method of color photography which, he said, by its simplicity and the beauty of its productions, had ousted all other methods for amateur work.

# "Say Pop, when are you going to get through?"

## *How the correct grade of Gargoyle Mobiloils cuts down Sunday morning tinkering*

SUNDAY morning, clear and cool; the week-end guests on hand; and the open road beckoning—

And then the endless Sunday morning tinkering while the family and guests walk impatiently up and down the lawn. *"When are you going to get through?"*

If you have to clean your spark plugs at frequent intervals, the chances are that you are using lubricating oil of incorrect body or low quality *"When are you going to get through?"*

If the compression is weak and your engine seems to lack power, it is probably because your oil tails to properly seal the piston rings. Results:—weak compression, loss of power, and dilution of lubricating oil. *"When are you going to get through?"*

The loss of power and irregular action may be due to sticky valves. Sticky valves usually result from the use of the wrong oil. *"When are you going to get through?"*

REPAIR SHOP RECORDS show that about 50% of all engine troubles are caused by incorrect lubrication.

These troubles are by no means confined to the three mentioned above. Other troubles commonly caused by incorrect lubrication are—piston-rings badly gummed or stuck in their recesses, smoky exhaust, worn wrist-pin or crank shaft bearings, scored cylinder walls, engine overheated, carbon deposit and pre-ignition.

The motorist who uses the grade of Gargoyle Mobiloils specified for his car enlists *scientific lubrication* on his side and cuts down Sunday morning tinkering.

*"When are you going to get through?"*

GARGOYLE

# Mobiloils

*A grade for each type of Motor*

## *Correct*
## AUTOMOBILE LUBRICATION

GARGOYLE

# Mobiloils

*A grade for each type of motor*

**Gargoyle Mobiloils for engine lubrication are:**

**Gargoyle Mobiloil "A"**
**Gargoyle Mobiloil "B"**
**Gargoyle Mobiloil "BB"**
**Gargoyle Mobiloil Arctic**

The Chart below indicates the grade recommended by the Vacuum Oil Company's Board of Engineers. The recommendations cover all models of both passenger and commercial vehicles unless otherwise noted. If your car is not listed in this partial Chart, send for booklet "Correct Lubrication" which lists the correct grades for *all* cars.

## Beautiful Bodies Help Sell Motor Cars

ANY motor car builder will admit that a large number of cars is sold on "looks." As a result, the finishing of bodies and all enameled parts such as fenders, wheels, tanks, etc., is a process that requires most careful consideration and the best equipment available. In this process, the electric oven has come to the front through its obvious advantages over old-fashioned methods of baking. Its use greatly increases production, thereby reducing the unit cost, even with higher rates for power than for fuel. Electric heat produces a lustrous, hard finish so essential for lasting beauty, and it requires less time than other forms of heat, with more accurate control, greater safety, and practically no defective work that must be done a second time.

The flexibility of electric heat is remarkable since it permits the use of varying degrees of heat in different parts of the same oven or furnace. For this reason, electric heat is rapidly being applied to the baking of varnish, enamel, japan, and other finishes; to the melting of metals and alloys; to the heating of steel so that it may be chemically treated; to the drying of salts, sand cores, pottery and grinding wheels; to the heating of rivets, soldering irons, etc.; and even to the sherardizing of steel to make it rustproof by depositing on its surface a coating of zinc about twenty-five ten-thousandths of an inch thick.

To every one of the many uses of electric heat the General Electric Company has contributed in a broad way, until today the mark G-E on any electric heating device is the mark of the master. Thus it is to any manufacturer's advantage to consult G-E engineers before selecting such equipment.

**Bird's-eye view of Long Island looking toward New York City, showing the grounds, antennæ system and building of the New York Radio Central Station to be constructed**

## The Last Word in Wireless—The New York Radio Central Station

FOR more than two decades the wonders of wireless have so unceasingly intrigued the public imagination that it would appear little remained to be accomplished in developments of revolutionary character. Yet, once again, it is disclosed that a startling conception in wireless communication has been quietly brought to a point of realization. On the north shore of Long Island, near New York, a leading American radio company is about to begin construction of a super-powered radio station that will simultaneously send to and receive messages from five great nations of other continents.

The new and great medium of far-reaching economic and political influence will bear the name of *New York Radio Central Station*, the steel towers of which will rise on a 6,400-acre tract, comprising nearly ten square miles of land lying east of Port Jefferson, with a long frontage on Long Island Sound. The preliminary engineering studies have been completed, contracts for all the construction materials are being let, and a force of radio experts, after months of preparation, will immediately take the big job in hand.

A definite idea of the ultra-modern character of this radio plant may be gained from the observations of Edward J. Nally, president of the Radio Corporation of America (a combination of the General Electric Company and the former Marconi Company) under whose direction the world wide wireless system has emerged from an idea into a reality. "Everyone at all familiar with wireless," said Mr. Nally, "knows that at Nauen, Germany, and Bordeaux, France, are two of the largest stations in the world. Up to now they have been viewed with admiration; consider, then, the tremendous advance represented in this latest step: the New York Radio Central Station in the aggregate will be five times more powerful than either of these."

He explained that there will be five complete transmitters, each one a duplex unit with a corresponding receiving station located near by. All five transmitters and the five receivers will operate simultaneously and will transmit and receive messages over thousands of miles continuously day and night.

The form of aerial construction, too, is wholly a new departure. From the central power house six spans of aerial wire will radiate out in a star pattern to a distance of more than one mile from the center. The wires of this huge antenna will be supported on self-supporting steel towers, each 400 feet in height, with the wires suspended at the top between 150-foot cross arms. Each of the six antennæ will have twelve towers, forming so to speak the spokes of a giant wheel fashioned out of seventy-two miniature replicas of the famous Eiffel Tower in France. Five of these antennæ spokes will be used for regular service while the sixth is reserved for emergency operation.

Far more impressive than physical appearance, however, will be the things the eye cannot encompass. Appreciate, that in the wires forming each spoke of the gigantic wheel there will be generated a power equal to the greatest of present day transoceanic wireless stations; then comprehend, if you can, the fact that all five of these powers can, if desired, be combined into one, for signaling. A telegraphic signal created out of such tremendous electromagnetic energy could encircle the entire globe!

But that is not all. The apparatus and system which will be installed for each of the five units will be the same as that at present in our New Brunswick (N. J.) station from which the voice of Secretary of the Navy Daniels was carried to President Wilson when he was at sea aboard the U.S.S. "George Washington." In a number of experimental tests the voice has been carried by this radio telephone over distances of 2,500 miles with complete success. This leads us to state very definitely that before long a direct wireless telephone service will be established with foreign countries.

Every exacting requirement of commercial radio message service will be satisfied fully in the apparatus and system of circuits with which the great station will be equipped. The generation of the energy required to span thousands of miles will be effected by Alexanderson alternators, which have made it possible to carry the radio signals through space by continuous wave trains instead of by the interrupted or discontinuous waves generated by systems using the old-time "spark discharge" apparatus. In the Alexanderson alternator equipment the new station will have a source of energy proven as reliable as the power dynamo, yet creating a steady stream of electromagnetic oscillations, which will permit telegraphic signaling at very high speeds.

So efficient and reliable has the Alexanderson 200-kilowatt alternator installed at New Brunswick proven itself, that leading radio experts of Europe have made special trips of investigation to the United States to view its performance; now this already famous single

## A Real Start in Aeronautics

WE cannot commend too highly the plans of the Post Office Department for establishing, in addition to its own transcontinental airplane service between New York and San Francisco, four other routes between leading cities of the country, which are to be operated by private contract. Congress has made an appropriation of over one million dollars for the service to be operated by the Post Office Department from New York City by way of Cleveland, Chicago and Omaha, to San Francisco. The first routes to be established by the Government will be those for which the Post Office Department is now asking bids, as follows:

Cleveland-Detroit, 95 miles by air; 1,000 pounds of mail per trip. Pittsburg-St. Louis, 600 miles; 1,500 pounds of mail. New York-Pittsburgh-Chicago, 735 miles; 1,500 pounds of mail. New-York-Atlanta, 815 miles; 1,500 pounds of mail. In each case one trip each way 306 days in the year, with leading intermediate stops (except, of course, between Cleveland and Detroit).

In drawing up the specifications the Post Office has been able to call upon its own extended experience during the two years' operation of its air mail service, and it states that any type of modern airplane can easily perform the service.

In a recent issue we quoted from a paper lately read by Colonel Vincent, in which he stated that the most practicable way for the Government to promote commercial aviation in the United States would be by the extension of its air mail service. This it is now about to do, and on a scale that will vigorously stimulate what threatened to become a moribund industry. To set up these five great routes and maintain them will call for a large and steady output of airplanes, and we have no doubt that the states and cities affected will come forward with generous assistance in providing the necessary sites for the many landing fields that must be provided.

If this great venture shall prove to be a success—and the Department would never have launched out so boldly unless its two years' experience gave good promise of success—we may look for an eventual revival of our airplane industry upon a steadily increasing scale.

## About That Einstein Prize

SOMEBODY has asked us what we hope to accomplish by the five-thousand-dollar prize competition which we announced two weeks ago. Our interrogator points out that for five to ten years the Einstein theories have been quite familiar to those mathematicians whose interest lay in the field which would draw their attention to this work. He calls our personal attention to the fact that as long ago as 1914 we were in the habit of dodging discussion with him of the mathematical aspects of relativity. He points out that since the incident of the eclipse several books on the subject have appeared, to say nothing of a quantity of magazine articles. His general viewpoint seems to be a doubt that anything can be done in a three-thousand-word essay which has not been done in one or several of these.

It is in the thought that this viewpoint may be somewhat general that we write these few words. We have not the slightest idea that the essay competition is going to bring out any new knowledge, that the winner or any of the other contestants will be able to say anything about the Einstein theories that is not already a matter of knowledge and of record. But that is not the point.

Of all these books, we should say that Dr. Eddington's is most nearly complete and possessed of greatest scientific value, and that Dr. Slosson's has the best appeal to the reader who is not versed in the devious ways of those mathematical fields that make the calculus look like the merest elements of the subject. But in both these books there are plenty of places that are pretty tough reading; we do not believe that anyone not a mathematician can read through either book conscentiously without getting lost more or less frequently.

An essay of three thousand words is not long enough to lose a reader more than once; if it does lose him it is a failure, and if it doesn't it is a competitor that will go into the final elimination trials for the prize. If we can present, as a result of the contest, six or a dozen essays of this length that will not lose the lay reader at all, we shall have produced something amply worth the expenditure of Mr. Higgins' money and our time. For such a number of essays of such character will of necessity present many different aspects of the Einstein theories, and in many different ways, and in doing so will contribute greatly to the popular enlightenment.

Really the significant part of what has already appeared is not the part that is intelligible, but rather the part that, being unintelligible, casts the shadow of doubt and suspicion on the whole. The successful competitor for the prize and his close contestants will have written essays that, without any claim to completeness, will emphasize what seems to each author the big outstanding feature; and every one of them will be intelligible. Together they will in all probability be reasonably complete, and will retain the individual characteristic of intelligibility. They will approach the various parts of the field from various directions—we could fill this page with suggestions as to how the one item of the four-dimensional character of Einstein's time-space might be set forth for the general reader. And when a man must say in three thousand words as much as he can of what eminent scientists have said in a whole volume—well, the result in some cases will be sheer failure, and in others a product of the first water. The best of the essays will shine through intelligent selection of what is to be said, and brilliant success in saying it. It is to get a group of essays of this character, not to get new knowledge of relativity, that the prize is offered.

## General Crozier on Our Ordnance Effort

NO phase of our preparation for the war attracted so much attention as the provision of ordnance for our rapidly forming armies. It is not generally known that ordnance constituted by far the largest single item of expense. The Bureau of Ordnance had on its books on the date of the armistice some fourteen billions of dollars of which, if we remember rightly, nearly one-half was expended. Naturally the citizen will ask: "Why were these enormous sums necessary? And why was it, with funds so lavishly provided, that we were so largely dependent upon our allies for field and heavy artillery, and, in less measure, at the outset of our field operations, for rifles and machine guns?" The answer to these questions is given in a very clear, precise and straightforward way by Major General William Crozier, Chief of the Bureau of Ordnance, now retired, in a book entitled "Ordnance and the World War." "Everybody now knows," says the author, "that we entered the war with a very small army and a totally inadequate supply of arms, ammunition and other equipment. But there are some who do not know why it took so long a time to raise the war army and transport it to Europe, or why its supply of certain American-made munitions was so long delayed."

The public, in a spirit of good sportsmanship, if we may put it that way, should welcome a work of this kind from any military man whose administration has been subjected to criticism; he is prevented, while in the service, from telling the simple facts which would set him right in the eyes of the nation. There is a world of meaning in the last clause of the introductory chapter in which the General says: "I should add that, having retired from active service, I am no longer a part of the War Department or of the Army with the Colors. I therefore speak without official authority, and with something of the freedom of any other citizen."

Naturally, the chapters dealing with machine guns will attract the most attention, this because of the long controversy which raged around the question of the delay in the adoption of the Lewis machine gun. General Crozier has adopted the wise course of giving a succinct statement of the various tests which were made by the War Department of the various types of machine guns, including the Lewis gun, offered to the Government, and the facts as thus presented will enable any civilian to judge for himself the merits of the case.

Because these weapons operate with tremendous pressure and enormous velocity of moving parts, the General tells us that "no entirely satisfactory machine gun has yet been developed, that is to say, we have never had a machine gun that is not subject to stoppage by reason of some kind of malfunction," although the Browning gun is a great advance in this respect. Speaking of the service rendered, he says that the Benet-Mercier gives out about one horse-power for each pound of its weight, which is approximately double the output per pound of the Liberty engine.

In 1913 the Ordnance Department arranged a competitive test of automatic machine rifles at which all of the seven competing guns were eliminated except the Benet-Mercier and the Vickers; and in the subsequent field test, in the spring of 1914, the Vickers gun was selected. The report stated that in the endurance test there were with the Lewis gun 206 jams and malfunctions; with the Vickers gun, 23; and with the Benet-Mercier, 59. The next test took place at the Springfield Armory in April, 1916, when the service gun was withdrawn by the makers on the ground that it was in an experimental stage. The War Department Board found that the Lewis gun, in its then stage of development, was not as reliable as the other guns tested, the number of jams and malfunctions of the Lewis gun being 314 as against 59 of the Springfield and 23 for the Vickers gun, the duration of the firing being respectively 123 minutes, 147 minutes and 84 minutes. "The Lewis gun," the report goes on to say, "is lighter, simpler, and has a fewer number of parts than the other guns mentioned." These results were borne out by experience had on the Mexican border in the same year. General Crozier quotes a report of the School of Musketry as saying, "The Lewis gun, while it is not a dependable weapon at present, is believed to possess great possibilities."

As a matter of fact the interests which had the Lewis gun in hand during this period were turning out a very much better weapon in Great Britain than they were in this country, and it was only a question of time when the Lewis gun would be found available for our own service. As General Crozier says, "It must be remembered that no Lewis gun, as made in England for the British service, had ever been available in the United States, even for test." He tells us that throughout the winter and in the early spring of 1917, over fifteen important changes had been made in the gun. That it had now been brought to a state of practicability for use with American ammunition was shown by a test held under the auspices of the Navy Department. Consequently, after our entrance into the war and as soon as funds were available, the Ordnance Department ordered 4,400 Lewis guns, and after a test by the War Department Machine-Gun Board in May, 1917, they reported that the Lewis machine gun, caliber .30, fully established its character as a first-class machine gun. Following this report, Lewis guns were ordered as funds became available.

When our plants had been established and were going at full pressure, the output of machine guns and automatic rifles of the Vickers, Lewis, Colt-Marlin and Browning types was 180,000 at the date of the armistice, and our rate of manufacture reached a point such as to remove all fear that our troops might lack a sufficient number of weapons of this class.

## Electricity

**Electric Shock Aid.**—The National Safety Council of Chicago, Ill., has issued a large wall bulletin suitable for putting on the walls of power houses and central-station buildings, giving the rules adopted by the National Electric Light Association for using the prone pressure method of resuscitation for electric shock. The bulletin is illustrated with three cuts showing the application of the treatment. The council has also issued pamphlet No. 29, entitled "Electrical Equipment in Industrial Plants," which, according to a subtitle, is "an orderly presentation in loose-leaf form of ancient hazards and the best practises for their elimination."

**VibrationGalvanometers** are useful in null measurements but have not been used in industrial laboratories because they are sensitive to external vibrations and require delicate adjustments. The present instrument, which has a sensitivity higher than other forms of the moving-iron type but less than that of the most sensitive forms of the moving-coil type, has the advantages of sturdiness, quick responsiveness and freedom from the effects of external vibration. It consists essentially of a fine steel wire mounted on one pole of a permanent magnet and so arranged that the free end of the wire may vibrate between the poles of an electromagnet through which the current to be detected passes.

**Cadmium-Vapor Arc Lamp.**—The Bureau of Standards, Washington, D. C., has announced, through Scientific Paper No. 371, the development of a new method of producing a cadmium vapor arc of great brilliancy. It was found that the metal gallium alloyed with cadmium, and since gallium has a boiling point above 1,500°C., the vapor-pressure relation which exists between cadmium and mercury is reversed when compared with cadmium and gallium. The cadmium therefore acts as the energy carrier when used in combination with gallium in a quartz lamp. The cadmium-vapor lamp may be operated with a current of three amperes and a drop of 14 volts across the terminals, but gives the best results when operated at about 25 volts. Under this condition a practically pure cadmium spectrum is obtained. The lamp is expected to fill a demand for a light source of this character.

**Resistance for Rheostats.**—Where resistances are formed of spirals of wire, the sections of the wires must be so determined that the cooling surface per unit of power is constant, depending on cooling conditions. In an article appearing in a French periodical, it is demonstrated mathematically how a saving of metal may be effected by using several wires in parallel instead of a single one. The volume and, consequently, the weight of wire used for the resistance, is the less the more wires in parallel are used; a resistance formed of a single wire weighs 3.3 times as much as the same resistance of six wires in parallel. Of course, the dimensions of the rheostat and the cost of labor increase with the number of wires, so that there is an economic number for each case. If the resistances are formed of bands of very thin wires, with which the section is proportional to current density, the weight of metal is constant whatever the number of conductors in parallel, so that it is usually best to take a single conductor.

**Double-Base Incandescent Lamp.**—A new double-base lamp by means of which household appliances and fixtures may be used simultaneously from the same outlet without the use of double plugs or adapters has been developed by E. O. Schweitzer, chief testing engineer of the Commonwealth Edison Company of Chicago. The lamp may be made up in any style and capacity. The lead-in wires are those used for the standard 500-watt lamp and continue through the bulb from base to base, the lamp filament being tapped off from them. The lead-in wires, which are formed into an expansion loop to eliminate strain due to unequal contraction and expansion of the lamp elements, are made with a quarter twist to provide clearance for the filament anchors. Exhaustion is carried out through a concealed tube within one of the bases, continues *Electrical World*, thus making a tipless lamp. By the addition of a light brass shell beaded at each end any standard shade holder may be used. The extra attachment to the lamp may be made by using a socket screwed to its free base.

## Science

**A Board of Surveys and Maps** has been created by executive order, for the purpose of coördinating the activities of the map-making agencies of the United States Government.

**A Notable Contribution to Palæobotany** is Dr. F. H. Knowlton's "Catalogue of the Mesozoic and Cenozoic Plants of North America," published as U. S. Geological Survey Bulletin 696. The work contains bibliographic references to about 735 genera and about 4150 named species and varieties of plants found in the Mesozoic and Cenozoic of the United States and Canada, and makes a ponderous volume. The bibliography contains 474 titles.

**The Leucoscope in Pyrometry.**—The Bureau of Standards has recently been making experiments with the leucoscope, an instrument devised many years ago by Helmholtz for light and color analysis, and finds that this instrument, originally used in the study of vision, has useful applications in pyrometry. New laws have been discovered, relating the readings of the instrument to temperature and spectral energy distribution in a light source or furnace. The results of this investigation have been communicated to the Optical Society of America, for publication in its journal.

**The American Geophysical Union.**—The American section of the International Geophysical Union, which met in Brussels in July, 1919, has recently been reorganized and enlarged to form the American Geophysical Union. It is divided into six sections, which, with their chairmen, are as follows: (a) Geodesy, William Bowie; (b) seismology, H. F. Reid; (c) meteorology, C. F. Marvin; (d) terrestrial magnetism and electricity, L. A. Bauer; (e) physical oceanography, G. W. Littlehales; (f) volcanology, H. S. Washington. The secretary of the Union is Prof. Harry O. Wood, of Johns Hopkins University.

**Improvements in Map Projections.**—The U. S. Coast and Geodetic Survey has been devoting much attention of late to the subject of map projections, and has issued several interesting memoirs relating to projections which have been little used in this country, together with specimen maps. The latest publication of this sort is a new outline base map of the United States on the Lambert zenithal equal-area projection, scale 1:7,500,000. This is the first map on this projection ever published by the Survey. Besides its useful property of equal area, the projection has smaller scale and direction errors than the polyconic projection map which has been so frequently used for political, census, and miscellaneous statistical purposes.

**The Federal Board of Surveys and Maps,** created by an executive order of December 30, 1919, is now fully organized, with representatives from 14 map-publishing branches of the Government. At the initial meeting of the Board, in January, officers were elected for 1920, viz., O. C. Merrill, Forest Service, chairman; William Bowie, Coast and Geodetic Survey, vice-chairman; C. H. Birdseye, Geological Survey, secretary. Committees have been appointed on topographic maps, highway maps, hydrographic maps, photographic surveying, and several other special subjects. A Map Information Office has been organized, with headquarters at the U. S. Geological Survey. The establishment of this office is an event of much public interest, as it provides a central agency in Washington from which information can be promptly obtained concerning all map and survey data available in the numerous Government offices which carry on cartographic work of any kind. The new Federal Board is charged with the duties of making recommendation to the several departments of the Government or to the President for the purpose of coördinating the map-making and surveying activities of the Government and of settling all questions at issue between the departments relating to such subjects, within the limitations of existing laws. The Board is also directed to hold meetings at stated intervals, to which representatives of the map-using public shall be invited, for the purpose of conference and advice. These meetings will be held hereafter on the second Tuesday of January, March, May, September and November of each year.

## Industrial Efficiency

**Japan's Seaweed Pulp Industry.**—That the manufacture of paper pulp from seaweed is proving a profitable undertaking seems evidenced by the fact, reported by Consul General George H. Scidmore, that the only company manufacturing this pulp is building another factory. This concern was organized in December, 1919, and is producing, by a secret process, about 50 tons of pulp daily, which is largely used in the composition of cigarette paper. The new plant when completed will have a daily capacity of 150 tons of pulp. The present price is about 5 cents a pound.

**New Glass Industry.**—Important developments are eventually probable on the northern borders of Dartmoor, in Devonshire, England, in consequence of the discovery of a very large deposit of granulite, a substance of much value in the manufacture of glass. According to experts, "granulite contains not only silica, but potash, soda and alumina, which are necessary in glass making, and its use is not only economical but gives the best results in the production of glassware of the highest quality." It is stated that an experimental furnace has been in use for some time, two others are being constructed, and it is anticipated that the commercial manufacture of glass will commence almost immediately.

**Success of German Fairs.**—The success achieved at the first International Fair held in Frankfurt last fall has led the city authorities and especially the directors of chambers of commerce in several German cities to study the value of fairs as a medium for bringing together buyers and sellers not only in Germany but from all parts of the world with the object of fostering the intensive reconstruction program now occupying the business men of Germany. The city of Stuttgart leads all German cities in the number of fairs scheduled for 1920. A jewelry fair has just been held and reports have been received that it has been a great success for the exhibitors. Another jewelry fair will be held in September. A medical technical fair was held from April 5 to 18; photographic fair, May 2 to 16, and a book fair was planned for June. Fairs will be held in the following cities: Breslau, Danzig, Frankfurt, Cologne, Königsburg, Leipzig.

**Unique British Advertising Plan.**—The Federation of British Industries has devised a unique scheme for advertising home manufactures in all parts of the world. A new steamship to be called the "Federation" is to be constructed by some of the leading firms of the country as an exhibit of British marine engineering. The cargo of the ship will consist of various articles of British manufacture. Representatives of the firms interested will make the voyage for the purpose of showing their goods and interviewing foreign buyers. It is believed that a splendid opening will thus be afforded for extending British commerce in foreign countries. The first voyage will probably be made to the various ports of South America, and subsequent voyages will be made to the Mediterranean, Scandinavia, Baltic ports, the Far East, and Australia. Among the exhibits will be airplanes and airplane parts, and there will also be motion picture apparatus on board for the purpose of showing British films.

**Germany's Wood Problem.**—According to press reports, tremendous sums have been paid in Germany at public sales, not only for the State and community forest products, but also at auctions which took place in private woods. As early as last August the Central Government issued orders to the different State governments that home industries should be first protected in all wood sales. But these Government measures, taken in favor of the general consumer of wooden articles, seems to have had little effect. By selling the wood at a cheaper price to the wood-working industry the State has encountered some loss, notwithstanding which the prices of wood products have increased steadily, as is seen in the constantly rising prices of furniture; the profit remained in the hands of the wood-working industry. In addition to this, a constant export of wood into foreign countries, in spite of the export prohibition, is taking place. In consequence of this, more severe restrictions have been put into force, and it is possible that the wood trade will be licensed for the purpose of putting an end to the wild speculation and profiteering.

# Descendants of the Water-Wheel

## Installations for Developing Hydroelectric Power upon a Notable Scale

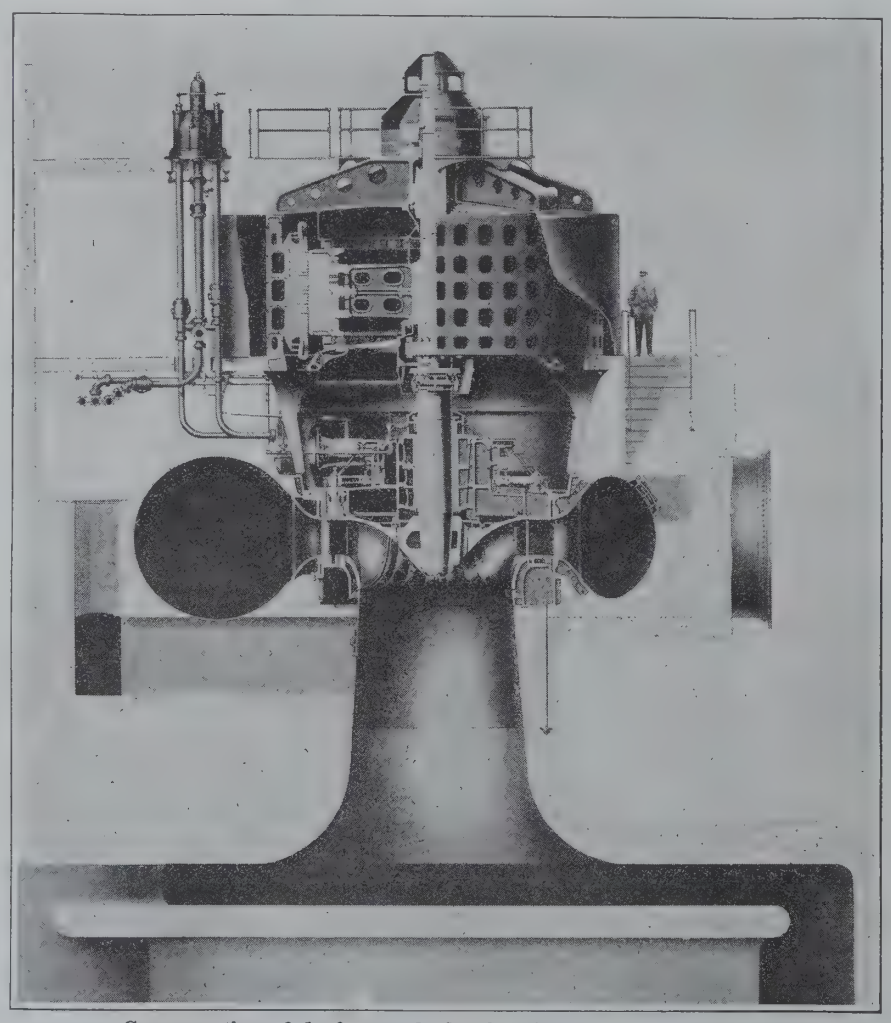
By J. F. Springer

FROM very early times men have sought to utilize the mechanical force exerted by the wind and the waterfall. The undershot water wheel is said to have been the first of the water-power devices, and the breast and overshot wheels are perhaps to be placed next in order. While these apparatus are not to be regarded as efficient in the modern sense, they are by no means obsolete. This is to be explained by the ease and economy with which they may be constructed and installed. It is often a matter of no moment whether there is waste of power water or not. At other times, however, it is of high importance to use the available water power to the greatest possible advantage. In such cases the modern designs must be called into service.

At present modern up-to-date water-power installations belong to one of two types—the Pelton and the Francis wheels. In general, Pelton wheels are mounted on a horizontal shaft; Francis turbines may be mounted upon either a horizontal or a vertical shaft. The Pelton wheel is driven by the force directly imparted by a jet of water. It is classed as an impulse device. In Francis turbines, the drive is effected more or less by reaction.

Notable installations of water turbine units are those at Niagara Falls, N. Y. The development calls for three gigantic units with vertical shafts. These operate big electric generators rotating in horizontal planes. There will be, presumably, three designs of electric generators, since three different concerns are to furnish them. One of these is also to supply the hydraulic unit as well; a fourth concern furnishes the water units for the two other generators. In one of the illustrations is a vertical elevation (partly sectional, partly cut away) showing one of the complete hydroelectric units. This is a vertical unit because the main shaft is vertical. It will be noted that this shaft is in two parts which are bolted together. The lower part belongs to the hydraulic unit and the upper one to the electric generator. Below the shaft is to be seen a great vertical conduit which increases in diameter as it descends. This is the draft tube—the earlier part of it. The spent water passes down and out through the draft tube. The water enters the horizontal water wheel—the runner—from an encircling conduit. This conduit is a very interesting affair. In the present case it consists of a big metal tube of continually diminishing diameter arranged to encircle the runner. Concrete has been the favorite material, but there seems to be some tendency of late to interpose a steel lining between the concrete and the water. The conduit is open pretty much all round its inner circumference. The circular opening is partially occupied by guides which accurately direct the water flowing inwardly from the conduit. The reason the conduit continually diminishes in diameter is that the purpose is to exhaust its supply of water by the time the complete circuit is made. In the figure, this conduit is seen in section at two points, one to the left and the other to the right of the bottom end of the shaft. Other views show the spiral conduit with the guides arranged in its inner circumference; and the framework which holds these guides in place, together with the several guides. The framework with its guide vanes is called a speed ring. In the present case it is of cast steel and has an exterior diameter of 20 feet.

If the reader will now return to the partly sectional view of the whole unit, he may discern the blades of the runner surrounding the bottom of the shaft. This is a tremendously important part of the hydraulic unit, being in fact the water wheel itself. It is secured to the shaft; so that when the water flows into the runner from the enveloping conduit through the openings in the speed ring, not only will the runner be rotated but also the shaft and the attached electric unit. In another view is seen a runner more or less different from the one belonging to the Niagara unit; but the reader will nevertheless understand the general appearance.



**Cross-section of the largest hydroelectric unit in the world, at Niagara Falls, N. Y.**

The Niagara Falls unit is to have an electric capacity of 32,500 kilowatts. When the water turbine rotates at the speed of 150 rotations per minute and the water has a head of 214 feet, its power capacity is 37,500 horse-power. The size of the whole affair may be judged by comparison with the man standing at the head of the steps on the floor of the generator room. In big units of this kind, it is desirable, not to say necessary, to provide brakes so that the whole apparatus may, upon occasion, be brought to rest. The generator is wound for 12,000 volts. This high voltage is necessary for transmission purposes. The rotating part of the generator—the rotor—naturally rotates at precisely the same speed as the runner; this 150 revolutions per minute is considered quite moderate. However, the enormous electric power is nevertheless produced. The moderate speed made it less difficult to design the rotor. If the runner attains "runaway speed"—that is, about 85 per cent overload—the stresses in the rotor will be not greater than one-third the elastic limit of the material. This means that the stresses will fall far short of effecting permanent deformations. The rotor with its shaft weighs 265,000 pounds. The fly-wheel effect developed by the rotor is 10,500,000 pounds per square foot.

In designing the gigantic unit, it was necessary to bear in mind that all the parts had to be lowered over a cliff to the power house at Niagara Falls. Further, even without this drastic requirement, the limitations of the means of transportation had to be kept in view.

The manner of supporting the rotating parts of a big unit like this is of interest. The rotor, the shaft and the runner are the principal items which go to make up the rotating load. In the present case, the support is near the top of the shaft. By referring to the partly sectional view, the reader may note the thrust bearing floating in oil. The outside diameter is 49 inches and the bearing is said to be capable of supporting 465,000 pounds. There are two guide bearings whose function is not to support weight but to maintain the shaft in exact position. One is located just below the thrust bearing. It is 36 inches long and has a diameter of 22 inches. When the unit is running at 150

## Fifteen Thousand Photographs per Second

By F. Honoré

AROUND 1880, shortly after the gelatino-silver bromide plates came into use, a cannon ball in motion was photographed for the first time. The snapshot showed simply a black line representing the trajectory. Later on, an Englishman succeeded in obtaining a picture of the projectile, which was then reckoned as a great achievement. Several years afterwards Professor Marey, desirous of analyzing the flight of pigeons, had a "photographic revolver" constructed, giving twelve snapshots per second. Today, in the same period of time, the ordinary motion picture machine takes from 20 to 250 views. Usually about fifteen are sufficient to obtain the desired impression. By means of special devices combined for scientific researches, M. Bull, Assistant Manager at the Marey Institute, succeeded in attaining a speed of 3,000 views and by using a process invented by M. Abraham, Professor of Physics at the "Ecole Normale," he is able to obtain photographs today at the rate of 15,000 per second. With more highly improved apparatus, he could theoretically obtain 50,000 and even more. These photographs which we are reproducing without any touching-up were recently presented to the Academy of Sciences. They show the successive positions of a revolver bullet and a 37-millimeter shell on part of their trajectory. We are showing below the manner in which M. Bull obtained this surprising result.

Such a quick photographic impression requires a considerable luminous power. On the other hand, it is impossible to imagine a shutter opening and closing 15,000 times during a second. It is therefore necessary to operate without shutter and use a source of artificial light which appears and disappears automatically in order to give intervals of darkness to replace the closing of the shutter. This source of light is given us by the electric spark of a condenser, a spark similar to the one which produces the Hertzian waves. The condenser may be loaded by means of storage batteries. The tension and frequency of the sparks may be adjusted as desired. With a tension of 10,000 volts and a frequency of from 10 to 15,000 sparks per second, the spark is about one millimeter long. If a film is revolving in a continuous movement in front of the electric source, this film will therefore be impressed 15,000 times per second by a spark. On the other hand, each spark lasting only a few millionths part of a second, the film, regardless of its speed, can be considered as being fixed during each pose and consequently the photograph will be very clear.

M. Bull makes the spark burst in the focus of a concave mirror of about 40 centimeters in diameter which reflects a parallel pencil of luminous rays which is crossed by the projectile. The latter shows a black silhouette (shadow) on the lighted background at the same intervals as those separating two successive sparks. In front of the point it must pass and at the same distance as the mirror a lens concentrates the luminous rays on the objective.

It is now necessary to receive the pictures on the film with a speed corresponding to that of the succession of sparks. The film, which is one meter long, is wound around a cylinder of the same circumference which moves on a horizontal axis and to which an electric motor gives a speed of 3,000 revolutions per minute, or 50 meters per second. The film makes therefore one revolution in 1/50th of a second. If 100 pic-

## Better Steel Ingots with Less Waste

By A. R. Surface

IMPROVEMENTS in the casting of steel into ingots are being constantly made but there are still many steel mills which adhere to the old practices. According to the old and long established practice it has been the custom and still is where it is used, to pour the molten steel into iron ingot-molds which are smaller at the top than they are at the bottom.

All steel, unless made direct into castings, is poured into some kind of an iron mold in which it solidifies before being further treated or manipulated. When poured into the old style iron molds, smaller at the top than they are at the bottom, they have the shape similar to the left-hand illustration, which shows such a steel ingot split in two, the original ingot being rectangular in shape. It is seen from this that there is a decided area of hollow or spongy steel extending well down into the ingot, nearly one-third down in fact. This portion of any ingot thus poured is worthless so far as further use for rolling or forging into finished products is concerned. It has to be removed, leaving only a portion of the original ingot available for further manipulation in the rolling mill. The amount of waste in a large steel mill where hundreds of these ingots are poured daily is very large. The discarded portion can only be used for remelting.

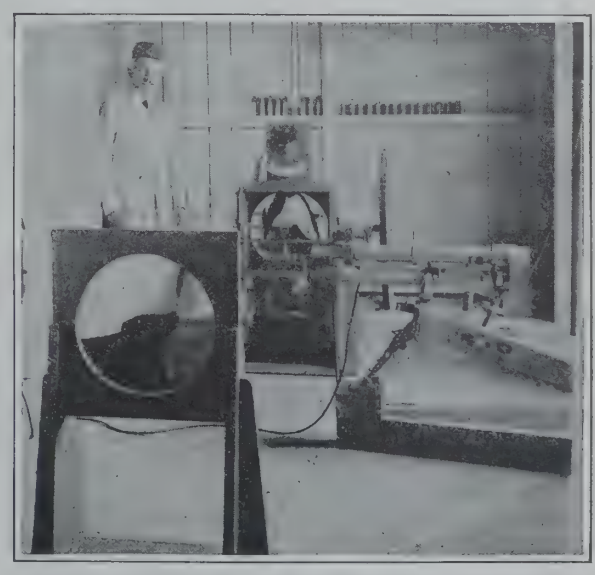
Realizing the waste involved and the advantage possible if this could be overcome, several metallurgists have devised ingot molds to overcome this. The product of one of the most successful, is shown by the other illustration at the right. This is the half of a steel ingot cast in an iron ingot-mold which is larger at the top than it is at the bottom and which uses on the top, when the steel is poured, what is called a "hot top" or sink-head—that is, the top of the iron mold is surrounded with a refractory substance which really builds up or extends the mold a few inches higher. After the steel has solidified in this, the refractory portion is broken away, leaving a protrusion on the end of the ingot.

The advantage of this practise can be readily and quickly seen. Instead of the large hollow spongy portion, called a pipe, which is so evident in the other case, there is in this case only a small hole or pipe which is confined to the extreme upper portion of the ingot and does not extend down into the actual ingot at all. It is plain that the amount of rejected steel in this case is relatively small and also that the quality of steel is considerably better.

It is stated that as approximately 3,000 tons of steel ingots are now produced daily in the United States in these improved molds, the average daily saving by means of this and other patented inventions of this nature is approximately $10,000 and perhaps much more.

## Chemical Warfare Service School

CHEMISTS generally have been gratified to learn that steps are being taken to establish a school where men may be trained for the Chemical Warfare Service and where recruits can be given the sort of training which will be very serviceable to them in peace times. Men who are without sufficient resources to gain a technical education can in this way gain the training which will be useful to them in war or peace. From the standpoint of chemical industry, such men would be found suitable as foremen and possibly superintendents in chemical plants.



General arrangement of the camera and appurtenances for 15,000 exposures per second of a moving projectile

# Lubricating the World

## Some Facts That Show Why We Are Short of Lubricating Oil, and a Few Suggested Remedies

By Eben Griffiths

THE world today is facing a shortage of all petroleum products. We have heard much of this shortage as affecting fuel oils, gasoline, etc., which today form an important part of the world's fuel. Another important phase of the problem is that of lubricating oil. This is the Mechanical Age. Power production has developed throughout the world to a remarkable state of efficiency. Power production demands lubrication, and we know that lubricating oil, like practically every other commodity, is selling today at prices far above what we used to consider the normal range.

What are the reasons for the present scarcity and high price? Is there a remedy in sight? These are the questions that are uppermost in the mind of every man who is using lubricating oil, whether on his automobile, his tractor, or on power machinery.

### Where the Demand Comes From

The answer to the first question will be found in the old-fashioned law of supply and demand. Lubricating oil is scarce and high because more people are trying to buy it than can be accommodated without severe strain on the available supply. Such a condition must result in scarcity and a high selling price.

The present tremendous demand for lubricating oil comes from two sources: First, there is a big demand for American lubricating oil in foreign countries; second, there is increased industrial and automotive development in the United States.

During the war producers of lubricating oil looked forward to peace as meaning a lessening in the demand for lubricating oil abroad. It has not worked out that way; for whereas, during 1918, the total exports of lubricating oil were 257,317,253 gallons, in 1919, when a decrease was expected, exports jumped to 277,591,158 gallons. That condition is typical of what has happened in most lines since the armistice was signed. The demand for lubricating oil and other products for reconstruction and industrial purposes under peace conditions, has been greater than the demands for war purposes.

The same thing has happened at home. Although industry was straining every nerve during the war to produce war materials, there has apparently been no decrease in production since peace was declared. While certain industries have slowed down, others have come forward at a rapid rate, with the net results that today the domestic demand for lubricating oil is greater than it has ever been before. So much for the conditions governing demand. Now let us turn for a moment to the consideration of the sources of supply.

### The Oil Supply

First of all, in considering our present supply we have to remember that when peace was declared, the oil industry had been straining every nerve to supply petroleum products for carrying on the war. Reserve stocks had been exhausted and we entered the peace period practically on a "hand-to-mouth" basis, so far as available oil stocks were concerned.

In the meantime, foreign sources of supply had been shut off. Russian crude oil is for all practical purposes, not available. The same is true of the Galician and Roumanian fields. The United States is today supplying the great bulk of lubricating oil used by the world.

On the other hand, production had been speeded up somewhat by war demands. New fields had been exploited. New wells had been opened up. But the increased supply was not equal to the increased demand. The result has been that today the better grades of crude oils are comparatively scarce. It naturally follows that they are high in price.

Four or five years ago, Pennsylvania crude oil sold for $1.35 a barrel. Today it is quoted at more than $6 a barrel, and it is usually necessary to pay a premium on top of the listed price to secure crude oil in any large quantity. Other crude oils have advanced in the same way. And the end is not in sight.

This, then, is a picture of conditions as they are today: A tremendously increased demand for lubricating oil at home and abroad finds reserve stocks exhausted, foreign oil fields out of the market, and production in the United States increased but not enough to take care of the increased demand.

### The Remedies

What are the remedies for the present situation?

First of all, we have the natural law which tends to harmonize supply and demand. High prices in themselves are a deterrent to use. We can safely count on some readjustment from this factor.

Much depends upon the foreign situation as regards credits and exchange. As credits to foreign countries are cut down it will naturally follow that less oil will be bought for export. It is also reasonable to assume that foreign production will soon become an important factor again. But the big remedy lies in an increased activity on the part of American capital in developing oil resources at home and abroad.

Much has been written about the threat to America's leadership in the oil industry. It has been said that England and other countries are endeavoring to usurp America's place as the leader in oil production. Of course, this is mere speculation, and looks far into the future in an effort to predict possibilities and not probabilities.

Few of us realize how great is America's leadership today in the production of oil. The United States today is producing about 70 per cent of the world's supply of petroleum. About 16 per cent is coming from Mexico, and about half of this Mexican supply is being produced by American capital. The other 14 per cent is coming from Central and South America, Russia, Roumania, Galicia and other spots of the world's domains. In 1916, the marketed production of petroleum products of the United States was 301,000,000 barrels; in 1917, 335,000,000; in 1918, 356,000,000. The United States Geological Survey estimates our unproduced but recoverable oil in January, 1919, as 6,740,000,000 barrels.

While the above does not indicate that the United States is in danger of being surpassed as a producer of petroleum, it is a fact that this country must be alert to the situation, and must not sit idle while other countries develop their resources.

America's opportunities are: To conserve and to develop the vast oil resources that still remain in this country; to enter whole-heartedly into the development of oil lands in foreign countries, especially in Mexico, Central America and South America; to discover the most practical and economical way of developing the shale oil deposits that lie in vast quantities in the Rocky Mountain states; and to urge and promote economy and efficiency in the handling and use of petroleum products.

### Oil Waste

This matter of the economical use of our oil supply is one of vast importance, not only to the country as a whole, but to each individual user of lubricating oil. Much of this waste occurs in the oil fields. Unlimited supplies in the past have brought about wasteful methods of recovering and storing oil. Vast quantities of oil run to waste every year in the oil fields. Oil men are today keenly alive to the situation, and able brains are devising ways of eliminating this waste.

But the waste which comes closer to most of us is that in the use of petroleum products. In lubricating oil alone, large quantities are wasted every year through unintelligent use. In almost every industrial plant more lubricating oil is used than is necessary to secure efficient lubrication. Oil is bought in quantities, and the application is usually in the hands of someone who is not especially interested in operating economy. He is interested, however, in "avoiding trouble," and his own idea of how best to avoid trouble is to "pour on plenty of oil." In that belief, lies one of the greatest fallacies in the world. "Plenty of oil" does not necessarily mean good lubrication. Correct lubrication consists of applying the right oil in the right places in the right way.

There are certain definite rules by which every user may help to eliminate waste in lubricating oil whether he is operating an automobile, a tractor, or an industrial plant. Perhaps the most important of all is to buy the correct oil for the purpose for which it is intended. This may sound like an academic statement, but it is strictly a matter of dollars and cents and oil conservation. We will all agree that no one oil will lubricate all types of machinery. We wouldn't use the same oil in a steam cylinder as we would on the shafting. We wouldn't use the same oil in our automobile engine as we would in the rear axle. But the difference does not stop there. For practically every lubricating need in any machinery, there is a correct oil, and there are hundreds of incorrect oils. If we use the correct oil, in nine cases out of ten we will use less of that oil than we would of an incorrect oil. In addition to that, there are resulting advantages in reduced friction, increased power, etc., which we need not go into here.

A second fundamental point is to use only high quality oils. In lubrication, perhaps as much as anywhere else, it is axiomatic that quality means true economy in the long run. High quality oils may cost more by the gallon, but they will cost less by the year, and we will be helping to eliminate waste of oil by using less gallonage.

Third, it is essential to install mechanical lubricating devices on machinery. We have already spoken of the fallacy that the more oil we put on the better lubrication we secure. One drop of oil at regular intervals will provide better lubrication than a lot of oil poured on at irregular intervals. For practically every lubricating requirement in every plant, there is available on the market a mechanical lubricating device which will supply regular and constant lubrication to the frictional surfaces without danger of too little lubrication and with the absolute elimination of waste in applying the oil.

Finally, we must prevent leakage from barrels or packages. A great deal of oil runs to waste every day in garages and in plants through careless handling and improper storing of barrels and packages. A leak of one small drop of lubricating oil per second from the faucet of a barrel means a loss of 34 gallons in a month.

The above suggestions are typical of many that might be made for the conservation of lubricating oil. It is essential that the American people practise this conservation in order to help bring about a return to a normal basis. Oil interests today are actively at work on remedies for the present situation. In order that they may have time to work out this problem properly, economy in the use of our present supplies is most important.

*THE acute character of the petroleum situation is, as yet, apparent to the general public only in the elevated price of gasoline, and in the occasional difficulty in buying this fuel at any price. We have touched upon several aspects of this in recent issues; but gasoline, as we have already pointed out, is only one of the petroleum derivatives. Just to what extent the shortage is felt in other directions, how serious the situation is outside the matter of gasoline, and what remedies may be looked for, are topics of importance second only to that of gasoline. So far as they relate to the field of lubricating oil, they are discussed in this article by a man who is thoroughly familiar with that field.*—THE EDITOR.

## The Detachable Broom Handle

THIS is the day of high-living costs—but it is also the day of new and crafty ways of sidestepping the onslaughts of the ugly ogre. The latest device to enlist on the side of the people is the detachable broom handle.

At first thought the broom handle seems inconsequential. Isolated and individually it is. Multiply it by some fifty millions or more, which probably approximates the number of brooms sold yearly in the United States, and you have something quite different.

The detachable broom handle is a brand new idea and it is taking. At the present time there is a factory in Vermont devoted exclusively to manufacturing brooms with this type of handle. The handle is of wood fitted into a metal holder that clamps easily on to the brush of the broom. The metal part is light, but very strong, being securely welded by the oxy-acetylene process, which not only makes it rigid but allows the entire piece to be neatly finished.

# Some Observations on Eggs

## Scientific Principles That Enter Where Least Expected and Are Carried Out Unrecognized

By John T. Bartlett

APPLIED science enters into the daily life of the city dweller at every turn; but the city dweller never has to worry about it. His applied science is attended to for him by somebody else, and comes to him in neat packages so that all he has to do is to turn a switch or lift a finger. But the farmer lives in smaller communities, much closer to nature; and while vast achievements have been recorded that go to make his life less isolated and less laborious, the general statement may still be made with a good deal of confidence that he must for the most part attend to his own applied science. He even has to go further than that in a good many cases and lay his own foundation of observational and experimental work—he may not realize that he is laying scientific foundations for future use at the moment, but that is what it really comes to. There are many illustrations that might be adduced to show that all this is so, but no space in which to adduce them all is available. A couple of the more striking will have to suffice and it happens to be convenient to take them from the same department of farming.

Take the matter of getting to market with the fragile hen-fruit. Scientists and inventors galore have worked on this problem, as the records of the patent office will demonstrate. Yet even before them, the farmer himself had learned that eggs may be driven to town without loss if they are packed in oats. The handy firkin is the rough-and-ready container, and packing is at hand in the feed room.

No matter how rutty, rocky and crooked the road to be traversed is, the contents are safe in this humble berth. The oats absorb the violent joltings and swayings. The eggs are traded in at the store without so much as a small crack. The packing is carried home and fed out. Then the storekeeper, having resort to an invention of comparatively recent years, the American egg case, opens carboard "fillers" and packs his fragile purchase for shipment to the large city market, where the eggs are either distributed for immediate consumption or placed in cold storage.

We in the United States are given to invention, and our egg case with its paper fillers is characteristic. Canadians are much like us. They use the same case we do. But because traffic in eggs thus packed reaches enormous annual proportions, we must not presume that this method is the only one followed or even the only quite practical one. It is not a perfect method, either. In fact, what the ultimate universal method of egg-packing will be, nobody knows, though naturally we Americans believe it will be of our development and in the direction already indicated.

It is entirely possible to use in a wholesale way, shipping long distances, the packing method which American farm-wives still use in carrying eggs to the village store. Chinese districts, for example, utilize two compartment cases in which oil cans have been shipped, and the packing material is hulls which act much as do oats. The Chinese second use of a commercial package is also paralleled in this country, where flour barrels are commonly used for apples and sacks for various products over and over again.

There was recently held in London an egg-and-poultry conference at which egg-packing methods were a foremost topic. We know our American method is not perfect, of course, but we are wedded to it. Its principal weakness is the fact that while eggs are not arbitrarily sized, the cardboard compartments must be. When eggs were much cheaper than now, this disadvantage was not of much consequence. The occasional breakage resulting when an egg was too large for the standard compartment did not matter much. A careful Yankee poultrykeeper shipping hatching-eggs in cardboard compartment containers is sure to wrap each egg loosely in newspaper fragments. There is an opportunity for some ambitious inventor to perfect our egg-packing materials, never losing sight of those important considerations, light weight and convenience. In rapidity of handling no method is the equal of ours.

The Danish way is to pack eggs in wood wool, the name given to a very fine kind of excelsior. The Danes are satisfied with their method. The bulky case in which they ship is so heavy that several men together must handle it. The Danish poultrymen find this works in their favor, preventing the careless, rough treatment, resulting in breakage, to which the Irish and American cases, both one-man affairs, are subject.

The writer has no data on the point, but it is a reasonable assumption that the capacity of the American case—thirty dozen— was determined in the beginning by the consideration which, in one respect, now works against it—a sensible size for the average man to handle unaided.

The Irish use still another packing method. They ship eggs between layers of straw. These layers are substantial, and if the packing is conscientious and after-handling reasonably careful, the eggs arrive at their destination with every individual specimen in good order.

While on the subject of eggs, it might not be out of order to point out that the big laying capacities which hens develop nowadays are also the result of more or less scientific investigation, of much the same impromptu sort that the farmer has given to the transportability of the eggs after their production. There is indeed a scientific principle involved in the unnatural stimulation of the egg-producing organs, which is often lost sight of, but which the farmer knows a good deal about, from his observations on domestic and wild fowl alike. For the domestic chicken was originally wild, and if we study the wild birds carefully we see the same principle, the mere existence of which has eluded the notice of most persons.

Take a recent case on a Western irrigated farm, where a meadow lark's nest, concealed in an alfalfa

### First Consideration for the New York State Barge Canal

To the Editor of the SCIENTIFIC AMERICAN:

I am interested in the article in your issue of June 19th, regarding a greater ship canal via the St. Lawrence to the sea, which to a novice may appear as an easy financial problem, because of the great sums of money which were so quickly raised for war emergency. I agree with you that our efforts should be expanded on the New York State Barge Canal, which is now in operation. Its promoters are now struggling with the State Finance Department to get a little more money to complete the general plan which includes the erection of terminal elevators. This will thoroughly relieve the East and West traffic between the Great Lakes and the sea.

I am a close student of this question of Lake-to-the-Sea Canals, and have an intimate knowledge of both routes. My fifty years of shipbuilding and maritime experience includes the building of more than 150 steel ships and the operating of many of them on rivers, canals, the Great Lakes and the ocean, and of some of them around the world. Before the Lower Canals were built, I personally built and took three large steel ships through the St. Lawrence Rapids to the sea; and some of these same ships, with others, I cut in two and brought back again to the Lakes. Before the Lower St. Lawrence Canals were finished, I ran the Rapids of the St. Lawrence in these interests more than twenty times. I personally sounded the shoal spots of the channel, except in the rapids, from Lake Ontario to Montreal. I have been called upon as expert witness by the Canadian Privy Council to give evidence relative to this outlet to the sea.

Just before the war I came from Liverpool to Montreal in order to study the gulf and inlet from the sea by use of ship's charts, and was given the privilege of viewing the river from an elevated position on board. The gulf is noted for its high tides and for the snow and fog in spring and fall, making it dangerous navigation. A ship wrecker of my acquaintance had twenty-two ship wrecks to salvage there in 1919. Notwithstanding this, doubtless there may some day be a large ship canal there, and also the original water route via the Ottawa River and Lake Nipissing between Montreal and Lake Huron. This route was intensively operated between Montreal and the Northwest from 1730 to 1830, and the success of the New York Canal may some day call for this as an outlet for ships.

For the past few years I have made trips along the construction of the New York Barge Canal, and have just returned from there. I have seen every lock in the main canal in operation. The slowest or deepest lock on the canal is at Little Falls, where I saw a tug and barge locked through in less than twenty minutes, without special effort. A large ship would take less time. I think ships could satisfactorily use the canal that measured 300 x 43 x 24 feet; that would carry about 5,000 net tons on the Lakes and coast, and through the canal about 4,000 cubic tons, or as much as 116 full-size box cars. When the state has granted a little more money to finish up the work, making passing stations on long levels, so that the large ships can pass each other, it may be possible to pass in one direction twenty million cubic tons of cargo in 220 days of the year. The effect of this on the cereal crop of the Great Lakes basin will amount to more than twenty million dollars per year at one cent per bushel. The amount of package freight from manufacturing companies will also be a large tonnage for Eastern consumption and export.

The building of the St. Lawrence Canal, as advocated by its boomers, would cost more than to build a larger canal from Oswego to Albany and New York, the route for which, including a connecting link from Lake Ontario to Lake Erie, has already been surveyed by our government engineers. The Welland Canal, to cost about seventy-five million dollars, is only about 25 per cent done, and will take many years to finish. When done, it will make a splendid outlet for both Canadian and United States tonnage via Oswego through the Barge Canal to New York.

Because of hostile propaganda against the Barge Canal the public has a wrong impression of this fine, useful, free waterway to the sea. An eminent engineer, who did much of the designing and planning of the Panama Canal and also of the New York Canal, tells me that the New York Canal is the greater of the two in work and skill. It is now in operation, and in one or more years will have 5,000-ton ships passing through that can trade to all parts of the world. When in smooth running order I think it will have more Canadian Lake ships pass through it than to Montreal, the Lake ships on both sides collecting cargoes at Lake ports for Eastern consumption and export, and returning with all kinds of imports. They will also bring U. S. coal from Utica and Watkins, the canals on both side being free for both U. S. and Canadian ships.

I think those who are agitating the St. Lawrence outlet have not fully considered the enormous opposition to it from the many trunk line railroads that parallel that waterway in both the United States and Canada. They have forgotten, also, the transfer points at the terminals: Port Colburn, Kingston, Montreal, Quebec, Halifax, St. John, Portland, Boston, New York, Philadelphia, Baltimore, Norfolk, etc. They should consider the Southern and Western States and provinces, which will be indifferent to, or against, the St. Lawrence project, at least until the *New York Ship Canal*, as it should be called, shall have demonstrated its value.

ALEXANDER MCDOUGALL.

Duluth, Minn.

### The Cruiser Courageous

To the Editor of the SCIENTIFIC AMERICAN:

In glancing through some back numbers of the SCIENTIFIC AMERICAN I found in the number dated December 21st, 1918, a picture of a two-funneled cruiser fitted as an airplane carrier described as the "Courageous." The SCIENTIFIC AMERICAN for June 21st, 1919, however, prints plans and profiles of various British ships which show the "Courageous" with only one funnel and the light cruiser "Raleigh" with two very like those of the aircraft carrier previously illustrated; so it seems certain that the so-called "Courageous," with two funnels, is really the new "Vindictive," originally named "Cavendish."

Havelock N. Hawke's Bay, New Zealand.

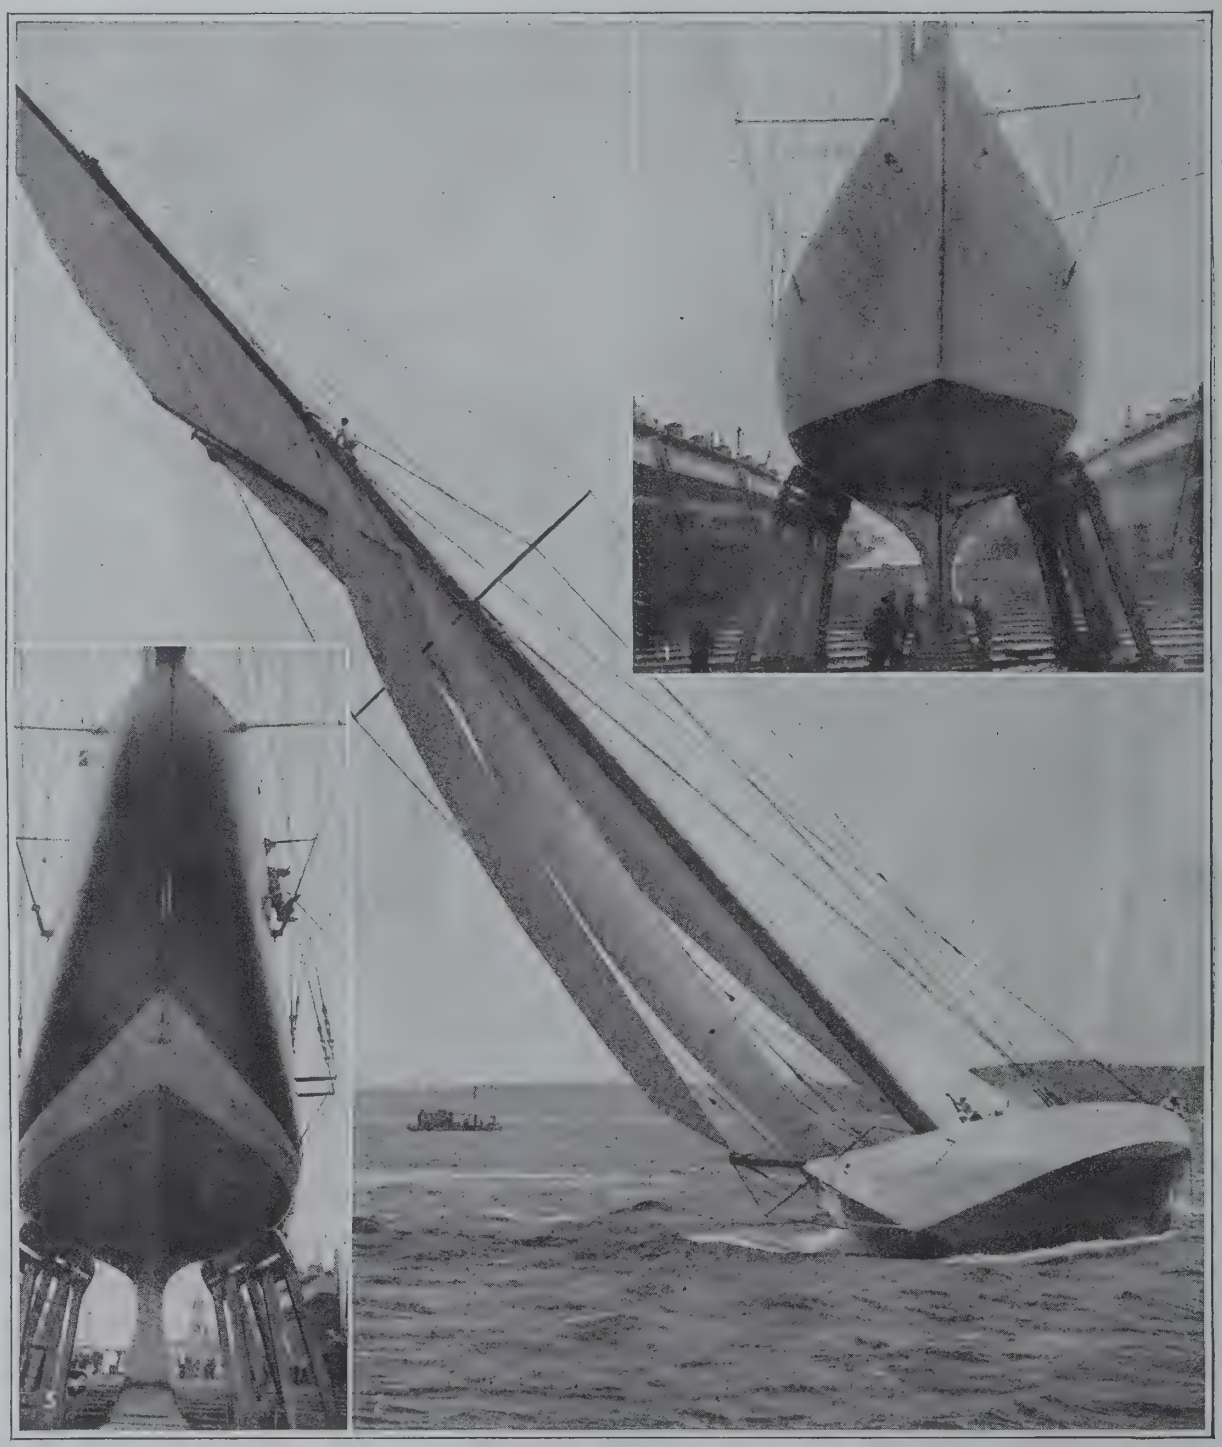
# Cutter Versus Sloop

## The Past Thirty-Five Years of Racing for the America's Cup

WITH each successive series of races for the America's Cup the SCIENTIFIC AMERICAN has published a set of diagrams of the contending yachts; and this year the presentation is brought up to date by the addition of the profiles and midship sections of the challenger and defender of 1920. The period from 1885 onward is the most interesting for the reason that the "Puritan" was the first defending yacht built specially to meet the challenger, and from the time of the "Thistle" onward all the British yachts have been built with a special view to "capturing" the Cup. Previous to 1885, the majority of the challenging and defending yachts were schooners. From 1885 to 1920 all of the boats, both British and American, have been single-stickers.

The "Genesta" (1885), the fastest of the British cutters of her day, was a thoroughly representative yacht. Because of a British rule of measurement which put a heavy tax upon beam, the British cutters were very narrow in proportion to their length and depth. They were heavily ballasted with lead, and they carried only a moderate amount of sail for their large displacement. The "Puritan," a typical American sloop, by Burgess of Boston, was a yacht of great beam, shallow draft and small displacement, carrying a large sail spread in comparison to her displacement. Thus, the "Genesta" spread 7,141 square feet on a displacement of 141 tons; whereas the "Puritan" of only 105½ tons carried 7,370 square feet. Apart from her great beam and shallow draft, the sloop was equipped with that distinctively American contrivance, the centerboard, which, in sailing against the wind, was lowered in order to give sufficient lateral plane to keep the yacht from making leeway.

The "Galatea" (1886), a big, heavily-built cruising cutter, should never have been sent over for the Cup. She had won but a few races on the other side, and although a very handsome cruiser, she had neither the handiness nor speed that would warrant her being matched against the fleet American sloops. "Mayflower" was designed by Burgess especially to meet her. She had a foot more beam and about a foot more draft than "Puritan," and on a displacement of 110½ tons she spread 8,800 square feet of sail as compared with 7,387 square feet of sail for the "Galatea," whose displacement was over 157 tons.



Left: "Shamrock IV." Center: "Resolute" closehauled. Right: "Resolute."

At this time the British abandoned their former rule of measurement and substituted one based upon length and sail area. With the tax upon beam removed, Mr. Watson designed the "Thistle" of 138 tons. The value of beam for sail-carrying was shown in the fact that the sail area went up from 7,387 feet in "Galatea" to 8,968 feet in "Thistle." Burgess, of Boston, designer of the "Puritan" and "Mayflower," brought out the "Volunteer," a sloop of 134 tons' displacement and spreading 9,271 square feet of sail. As compared with "Mayflower," the beam was decreased four inches and there was a slight increase in the draft. It should be noted that the "Volunteer" was built of steel. In all three series of races the American sloop proved to be more than a match for the British cutter, whose lateral plane was so greatly cut away that she could not point with the American boat.

Between 1887 and 1893, Watson had designed for the Prince of Wales, afterward King Edward VII, a very successful cutter, the "Britannia," which swept the boards in all the European races; and for the challenger of 1893, he designed "Valkyrie II," which was of the "Britannia" type. By the "Britannia" type we mean a cutter in which the lines are carried well out into the overhangings and all superfluous deadwood is cut away. "Valkyrie II" of 148 tons' displacement spread 10,042 square feet of sail. She had over two feet more beam than "Thistle," or 22½ feet; and her draft was between three and four feet greater. To meet her, Herreshoff designed the "Vigilant," a sloop with the enormous beam of 26 feet, four feet less draft than "Valkyrie II," and with 1,300 square feet more sail. Like all her predecessors, she was a centerboard sloop. In this series of 1893 the British began for the first time to show a speed that compared favorably with our American sloops. In the third race to windward and leeward, "Valkyrie II" beat the "Vigilant" to windward, but lost by 40 seconds on the run home because in the strong wind two of her spinnakers were blown away. The following year, "Vigilant" was taken over to race in English waters, and was frequently beaten by "Britannia." Hence it is not surprising that in the series of races of 1895 Herreshoff should have dropped the centerboard and built a yacht which in its profile and cross section approximated the new and very successful "Britannia" and "Valkyrie" type. His change from centerboard sloop to keel cutter was a logical development from his success in the smaller classes with "Gloriana" and "Wasp," which anticipated many of the features which characterized the "Valkyrie" and "Defender."

Just as Herreshoff was influenced by "Valkyrie" in designing the "Defender," so was Watson influenced by "Vigilant"; for "Valkyrie III" had the great beam of 26 feet 2 inches, or slightly more than that of "Vigilant." She had something of the full bilges and shallow hull of the American sloop, and on a displacement of 155 tons, spread 13,026 square feet of sail. "Defender" was built with a bronze underbody and aluminum-alloy topsides. She was a remarkably light boat in construction and weight, and on a displacement of 143 tons, she spread 12,640 square feet of sail.

For the races of 1899, Fife, a designer of scarcely less distinction than Watson, was selected to design "Shamrock I"; and to meet her Herreshoff turned out the "Columbia," probably his most successful yacht. In the next series of 1901, Watson was called in to design "Shamrock II" and the wonderful "Columbia," proving better than Herreshoff's new "Constitution," was selected once more for the defense of the Cup. "Shamrock II" proved to be by far the best boat sent to this side, as is proved by the small margins by which she lost the 1901 series. It is the opinion of many American yachtsmen that her failure to take the Cup was due to poor handling in the races. In 1903 Fife was called in again, and he turned out one of his characteristically beautiful boats with a very sweetly turned and admirably proportioned hull—a powerful craft spreading 14,337 square feet of sail. To meet her Herreshoff, influenced no doubt by the great speed shown by "Independence" with her scow-shaped hull, built a most extreme boat, the "Reliance," which on a waterline length of 89 feet 8 inches showed a total length of deck of 145 feet, and spread the enormous area of 16,169 square feet of sail. "Shamrock III" made a good fight for the Cup.

For the 1920 series, it was agreed that, for the sake of economy and all-round convenience, the length of challengers and defenders should be restricted to 75 feet on the waterline. The two boats are built under a rule which aims to prevent such extreme racing craft as "Reliance" and "Shamrock III." A premium is put upon displacement, and a heavy tax upon the sail and upon shallow-bodied, full-ended boats of the "Reliance" type. Herreshoff, in "Resolute," has turned out a small boat that aims to get every advantage possible from the rule. Nicholson, on the other hand, has accepted the penalties of the rule, particularly as regards sail area, of which his "Shamrock IV" carries about 20 per cent more than the defender, "Resolute."

DEVELOPMENT OF CHALLENGERS AND DEFENDERS OF AMERICA'S CUP FROM 1885 TO 1920

*Left:* Placing in the molds the hot syrup used in the manufacture of hard candies. Making hard candies is merely a miniature reproduction of ordinary foundry practice. *Center:* Slabs on which color and flavor are added to the fondant filling for chocolates. *Right:* The Jordan almond machine, where the nuts get their coating of hard sugar.

**Making sweets for the biggest candy-consumer among the world's nations**

# Uncle Samuel's Sweet Tooth

## Manufacturing Candy on a Huge Scale to Meet the Demands of the American People

By H. A. Mount

WE haven't the statistics, but we will venture the statement that if all the candy the average American girl eats in a year were placed end to end, it would reach the enormous distance of nearly half way around her appetite. But we can't blame it all on the boys and girls. Every member of the family has a hand in it and the total amount of candy consumed in the United States reaches the proportion of hundreds of tons a day. We are the greatest nation of candy eaters on earth and it has been said that all of the rest of the world combined eats less candy than we do. Our appetite for sweets supports a large industry, but it is not the purpose here to deluge you with facts, rather to show how this great quantity of candy is produced.

Like most of our modern industries candy-making has been greatly affected in recent years by the introduction of labor-saving methods and modern machinery. The most expensive candies, those which retail at two dollars a pound and upwards, are still made almost entirely by hand. They are cooked in small batches and in general follow the same sort of technique that sister uses in making fudge on the kitchen range. The output, it is true, may reach several tons a day, but this is accomplished by the addition of workers.

The next grade of candies, those retailing at from a dollar to two dollars a pound are also cooked in small batches, usually in kettles of about fifty pounds capacity. It is claimed by the makers that greater uniformity and better flavoring are thus secured. If a kettle full of candy is spoiled in the making it can be thrown away without much loss, whereas if larger quantities are made, the candy has to be "doctored up" and passed on to the consumer, who never suspects the trick.

In making the cheaper grades of candies, the bulk chocolates and the "hard tack" of school days, great kettles of as much as a thousand pounds capacity are used and machinery largely replaces hand labor in the production process.

Most candy manufacturers buy their chocolate in fifty pound bars from chocolate manufacturers. But some of the makers of fine candies buy the cocoa bean, roast and grind it, and add their own ingredients. It adds to the cost of the candy to make the chocolate in such small quantities, but the blend is "just right."

As the quality of candy goes up the proportion of nuts and fruits used increases. One manufacturer of an expensive brand of candy uses 35,000 pounds of nuts a year. And these must be whole nuts. The broken ones are used for cheaper grades. Likewise, in the most expensive candies only perfect fruit in large pieces is used and this is simply chocolate coated. In the next grade the small pieces of fruit are used and these are packed in a sugar filling and then chocolate coated. In the expensive candies pure fruit flavors are used and in the cheapest artificial flavors are sometimes employed.

A recent development in the candy business is the great increase in the sale of "unit goods," the tinfoil wrapped pieces that are for sale everywhere at from five to twenty-five cents a package. This has been brought about by the almost total disappearance of "penny goods," due to high prices. The child who once would have been given a penny for candy, now gets a nickel and he usually has to go back after another penny before he can buy anything. The candy makers have invented the "unit package" to satisfy this kind of trade and to tempt the man or woman who just wants something to "nibble at" while waiting for the train or a street car, in the park, or at the corner grocery store.

Perhaps the most striking feature about a big candy factory to the casual observer is the fewness of the big copper cooking kettles or vats. Only a few of these are required to cook the candy for a very large factory and they occupy only a small fraction of the floor space.

Usually the factory is divided into two or three departments, according to the nature of the products. One makes nothing but chocolate-covered candies, another bon-bons and a third "hard candies."

In the chocolate department the most important machine is the "fondant" machine. It makes the fondant or creamy filling that is the base of nearly all chocolates. The fondant, as every home candy-maker knows, is simply sugar and water, cooked to the consistency of very

### Handling the Reinforcing for Concrete Piles

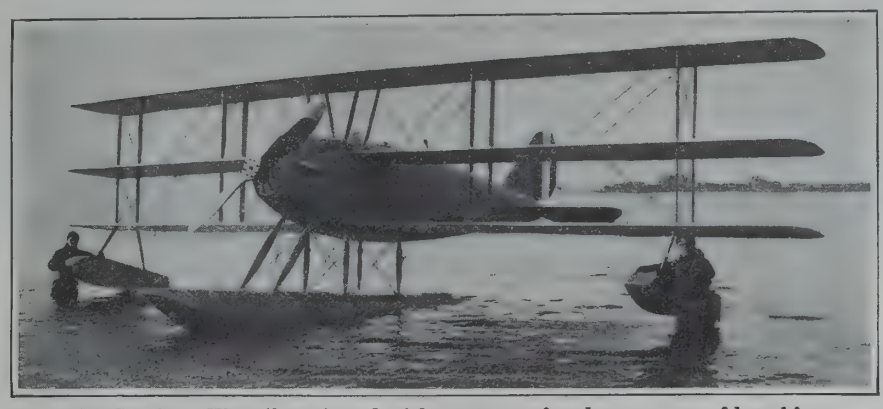
THE accompanying view shows the method of handling the reinforcing in very long piles, as used along the San Francisco waterfront. The reinforcing is assembled on five supports. When ready to be placed in position in the forms, three wooden horses are placed in position. There is a chain hoist on each of the horses, and the hoists are attached to the reinforcing, the reinforcing is raised clear of the supports and then moved to the right to a point directly over the wooden form, and then lowered into position in the form. A one-inch piece of wood is placed under the legs of the horses, so as to tip the horses slightly in the direction in which the reinforcing is to be moved.

Wooden forms and the supports for handling the reinforcing used in concrete piles

### The Fastest in Hydro-Airplanes

THE Curtiss "Wasp," equipped with pontoons, recently established what is claimed to be a new world's record in the Navy trials held at Rockaway, L. I., by traveling at the rate of 138 miles per hour. The 'plane, which is shown in the accompanying illustration, was piloted by Roland Rohlfs, the well-known Curtiss test pilot, and is the same machine in which he established new world's records for altitude and climb at Roosevelt Field last September.

The machine is now the property of the U. S. Navy and will be used at Hampton Roads, Va., for training purposes. The former world's hydro-airplane record was 126 miles per hour, held by the Curtiss HA hydro-airplane. The equipment of the Curtiss "Wasp" is a Curtiss 12-cylinder 400-horse-power engine.

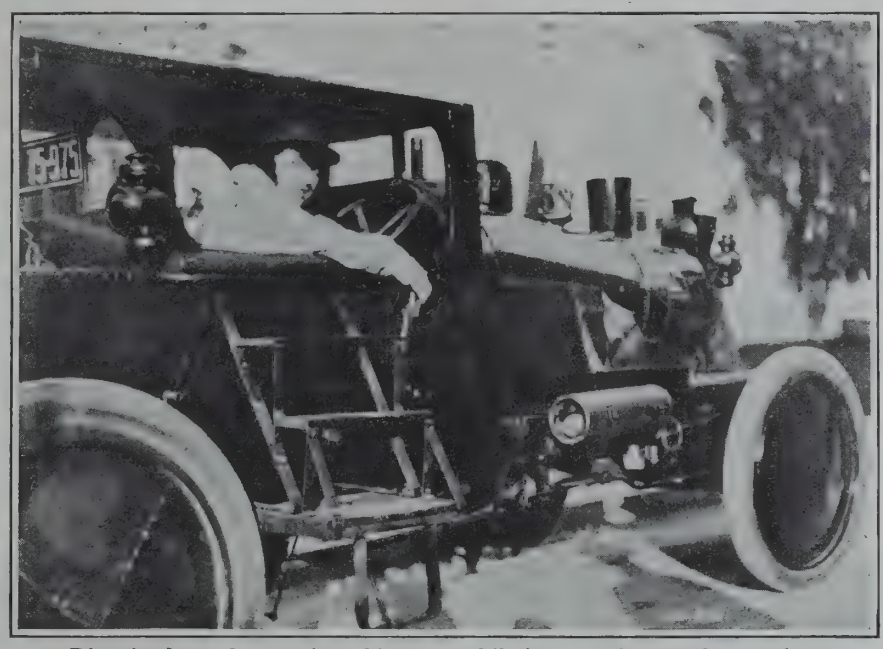


The Curtiss "Wasp" equipped with pontoons for the purpose of breaking the world's hydro-airplane speed records

### When a Locomotive Is an Automobile

CERTAIN progressive Californians have gone ahead with novel automobile designs. In fact, while most of us have been contented with such slight modifications as straight-lined bodies or angular mudguards, these Californians have come forth with the road locomotive, which is nothing more than a camouflaged automobile.

As a novelty, the road locomotive is a great success. It goes along the road at any speed, with clanging bell and a shrieky whistle. It undoubtedly gives a new twist or thrill to motoring. Otherwise it has no definite advantages over the usual motor car; if anything, it is more cumbersome and certainly less handsome.

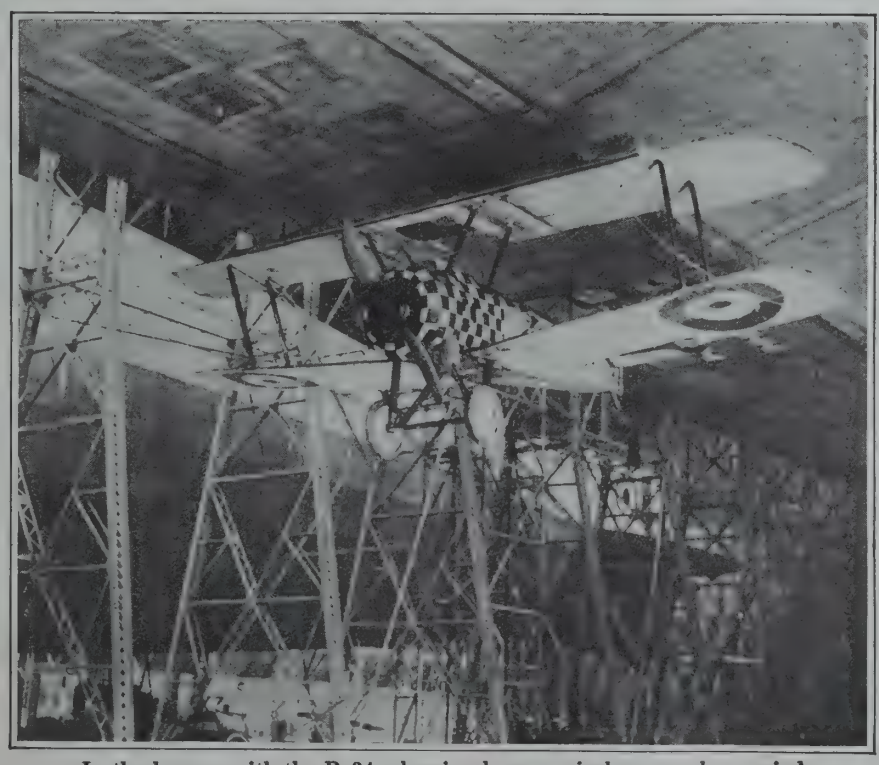


Disguised as a locomotive, this automobile is attracting much attention

### Airships That Carry Airplanes

THE helplessness of dirigibles in the face of airplane attacks may be considered a matter of the remote past. It seems that dirigibles of the near future will carry fast, single-seater fighting airplanes along with them for the purpose of defending themselves against airplane attacks.

The British, who appear to have taken the lead in dirigible construction and operation away from the Germans, have been carrying on extensive experiments with airplanes carried by dirigibles. The accompanying illustration shows the giant airship R-34—the dirigible which crossed the Atlantic last summer—in the hangar at Howden, Yorkshire, England, with an airplane suspended below it. The airplane can be reached by passing through a trap-door and down a swinging ladder to the airplane. At the opportune moment the airplane, with motor going at the proper speed, is released from the dirigible and after a very slight drop goes forth on its own flight. The disadvantage, of course, is that once the plane is launched, it is not possible for it to return to the airship, so that the latter will be as much at the mercy of a second attack from hostile planes as under old conditions it was to a first attack. But even immunity from a first attack is something.



In the hangar with the R-34, showing how an airplane can be carried

### Aerial Fish Patrol

A PEACE-TIME use for government airplanes has been found that may result in greatly enlarging one of the main industries of the coast states. This is the application of the planes to the location of schools of fish at sea and reporting the discovery by wireless to the canneries.

This new use for airplanes or seaplanes, as the type used in the work are called, first developed but a few months ago, following experiments which were being carried on from the North Island Naval Air Station at San Diego, California. Aviators had commented on numerous occasions upon the ease with which they could discern objects, animate and inanimate, in the depths of the sea.

It was on December 17th that the aerial fish patrol was officially organized at that station and the discovery of schools of sardines was radioed from the planes to the air station, whence word was quickly sent to the fishing fleets in the harbor, with the result that the first four boats to reach the area designated brought in, respectively, 1,165, 4,700, 19,200 and 3,245 pounds of the fish.

A few days later three fishing boats brought in a total of forty tons of sardines, and the success of the venture has continued every day since on which the planes have made their patrol flights.

The ocean in the vicinity of San Diego has been divided into sixty mile squares, as shown upon charts, and each of these squares is divided into ten mile squares. Upon the charts, which are furnished to all the naval air forces operating and to the fishing industries, the larger squares are given designated numbers, and so also are the smaller squares.

When a seaplane, flying at an altitude of some five hundred feet, passes over a patch of water which shows riffles, indicating the presence of a school of fish, the plane drops down closer to the water, where the observer can distinguish the variety of fish below him. If they prove to be sardines, the information is immediately sent by wireless to a subchaser which is usually stationed in the area to be patroled. If the fishing fleets are in the vicinity, awaiting the news, they are advised by means of a megaphone, the number of the large square being given first, followed by the number of the smaller square, with a third number designating the exact spot where the school has been seen. The sub-chaser also radios the information to the mainland, to the State Fish and Game Commissioner, who then advises all of the local fishing industries, the total lapsed time from the discovery until all have been informed seldom exceeding five minutes.

Until the inauguration of the aerial patrol, the fishermen started out with their fleets in the hope of locating schools of fish, but often had to return, disappointed and without a catch, but now the uncertainty has been succeeded by absolute assurance of a successful trip. Canneries which had been idle for some months, for lack of material, have since been running full time, and the canners are feeling more optimistic than ever before. Since genuine sardines are found only in Californian and southern European waters, the impetus which is now being given to the industry in California, through the aid of the government, bids fair to result in making that section the sardine canning center of the world.

As other fish, of the larger varieties, such as yellowtail, tuna, albacore and amberfish, begin to run, generally from early spring until late in autumn, it is anticipated by the canners that the seaplanes will continue to prove of great value, and that the average annual pack of these larger fish amounting to $2,000,000 in round numbers, will be increased to several times that figure.

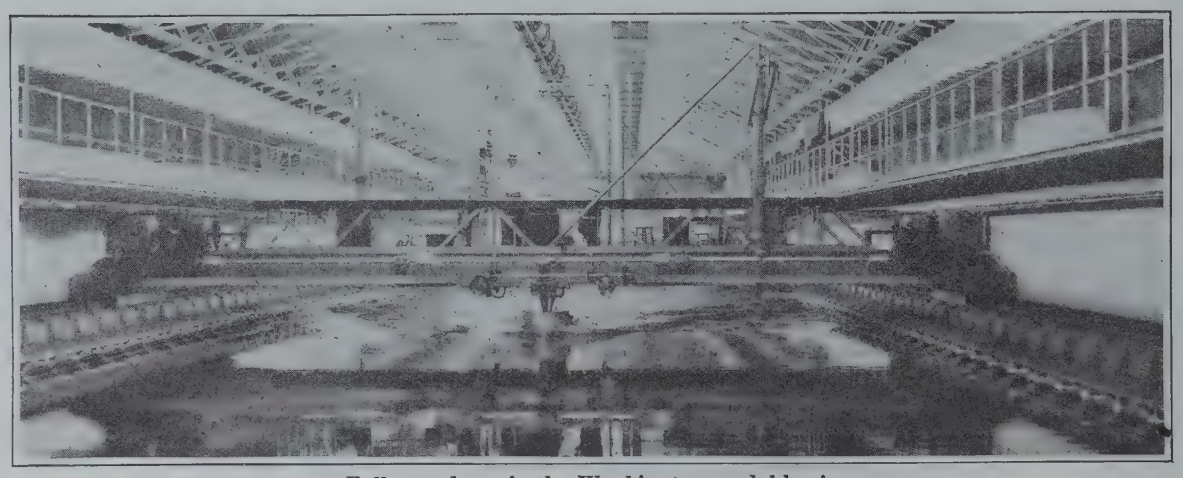
## Self-Propelled Models That Make for Better Ships and Less Fuel Consumption

By Robert G. Skerrett



Full-speed run in the Washington model basin

IT should be perfectly clear that the vessel which makes the best speed with the smallest fuel consumption is the vessel whose hull and propellers have the most advantageous shapes. It should be equally clear that in such a complicated matter as the shaping of these members, no general formula can ever be derived covering all the ground. The relation of displacement to resistance, of length and beam and other features, may be expressed in general terms. But the "shape of the hull" and the "shape of the propeller" are such complicated matters that we may be quite certain no formula can ever cover all their many ramifications. If we want to see how a certain shaped hull and a certain shaped propeller will behave, we must try it and see.

Obviously we cannot try it on the full-size, completed ship. A disappointing performance would be too costly. So we have the marine model, and the model-testing basin, and for many years we have had these. The practise has been to construct either wooden or paraffin models of comparatively miniature dimensions, corresponding in hull form to the lines of a contemplated full-size ship. The model is then towed beneath a carriage spanning the experimental basin and so attached to a dynamometer mechanism as to record in pounds and ounces the "pull" needful to move the miniature through the water at a speed mathematically proportioned to that of the proposed ocean-going craft.

Without going into details of a technical nature, it should be plain that the towing of an otherwise passive model can furnish data for the solution of only a part of the problem with which the naval architect and the marine engineer must contend. The dynamometer registers the total resistance to be overcome by the model in its progress through the water. This resistance is composed broadly of two dominating factors: first, skin friction set up between the water and the wetted surface of the hull, and second, the force expended in the creation of waves. Of the minor resistances, that of eddy making and certain reactions induced by the propeller are the most noteworthy. By towing independently of the model a thin plate of suitable length and area, representing the surface but not the form of the miniature's underbody, the skin-friction factor is obtained separately, and when this is deducted from the resistance of the model as a whole the remainder is the sum of wave and eddy resistances.

Until within the past three years this was as far as the model basin went in establishing the requirements of propulsive power for any given ship form. Incidentally, the model trials served to indicate the lines upon which the model should be modified to travel with less resistance and, therefore, with a reduced measure of horse-power. But this procedure left a considerable gap in the sequence of desired information. Even though the practise was to place a small propeller in position, subsequently, at the stern of the model, where it could revolve freely during towing, this test gave a very incomplete index of the real relation between the screw and the craft. The marine engineer had to resort to empirical formulæ to approximate the size of the motive plant he would have to build to furnish in actual horse-power enough energy to overcome frictional losses in the machinery, etc., so as to deliver against the water by means of the propeller or propellers the prescribed thrust in the form of effective horse-power. At the same time, he could not choose precisely the design of screw best fitted to translate the engine's drive into efficient effort upon the enveloping fluid.

The experts realized that they could go forward much more confidently in predetermining what a full-size vessel would do if her model could be tested both by towing and by self-propulsion. In the latter case it would be possible, with suitable apparatus, to choose the type of propeller best adapted to meet the needs of the particular ship form and speed and at the same time to learn to what extent the efficiency of the screw might be affected by the shape of the neighboring stern. Finally, a self-propelled model would lead to a definite figure covering the actual engine power essential to overcoming the external resistances called into being by the craft when underway.

The first experiments along these lines were carried out at the United States Model Basin in Washington in 1918 in connection with designs for single-screw ships. They have since been amplified and used in the testing of models for vessels to be equipped with quadruple screws, such as our gigantic battle-cruisers and our big scout cruisers—not to mention very large transatlantic liners. This research work has been made practicable, thanks to the adaptability of the electric motor and to the facility with which operating current can be measured to a nicety. But before describing the propelling equipment, it might be well to make plain some of the underlying phenomena that bear directly upon the action of the propeller insofar as it tends to increase the water's resistance to a craft's onward motion.

When advancing at considerable speed, a hull encounters resistance which manifests itself in the shape of a bow wave of more or less marked magnitude. A certain expression of this disturbance sweeps sternward, and in a well-designed ship this wave brings its crest just under the counter of the stern section—sweeping in against the vessel's body on both sides, thus inducing a squeezing action that forces her ahead. In this way, the wave of replacement as it is called, offsets the initial check caused by the opposing impulse of the bow wave. The form of the stern may be such as to emphasize or to lessen the helpful effect of the wave of replacement; and the agitation of the water occasioned by the propeller may further impair the beneficial work of the wave of replacement. It can be easily grasped that the churning screws set up, in addition to their greatly agitated eddying wakes, a rush of water toward them from ahead. Clearly, the hull must go forward against this; and with propellers translating a large block of horse-power into drive it is not difficult to grasp the fact that the reactions induced must be of considerable amplitude.

In single-screw models the model is driven by a small direct-current motor connected by means of a flexible coupling to the propeller shaft. The motor's armature shaft, however, is free to move in its bearings, fore and aft, for a distance of 7/16 of an inch, and by this motion to compress a nicely calibrated spring—this action being duly registered upon a revolving drum carrying a strip of paper. In this way, measurements of thrust are recorded in pounds and fractions thereof. Again, the frame of the motor is mounted so as to rotate in independent bearings, and, by another calibrated spring, the tendency of the frame to rotate can be read also in pounds—this figure indicating the torque. Other mechanisms give the factors of time, number of revolutions, the amount of electrical energy consumed, and the speed of the model. Where two, three or four propeller shafts are installed each one is equipped in the manner just described.

During self-propelled runs the miniature ship is not attached to the towing carriage, but is held by it to a straight course through the medium of vertical guide plates 10 inches wide with the edges set fore and aft, which move freely between flanking pins projecting downward from the under side of the carriage. The model can travel independently of the carriage for a longitudinal distance

## The Electrical Shoe-Shine

ELECTRICITY, operating through the medium of the vacuum cleaner and the clothes-washing machine, threatens to put out of business the old-fashioned household worker so far as the matter of supplying elbow grease is concerned. Now the busy little motor is making gestures that indicate a desire to make an end to the business of polishing shoes by force of arm. An enterprising boot-black of 42nd Street, New York, has installed an electric machine that does this, and does it well. So we may expect that eventually the chap who smears blacking on his hands for the purpose of getting the proper fine finish on the shoes of his customers will do so no more, but will be able to carry to work and home again the most elegantly manicured of snow-white digits, if his fancy runs in that direction. As to the machine itself, its construction and mode of action are sufficiently obvious from the photograph and the statement of what it is designed to do. We already have electric buffers and polishers, so it is no great departure to extend their operation to the matter of buffing and polishing shoes.

## Air-Washer for Tractor Engines

A NEW device that is somewhat similar in its action to a carburetor is designed particularly for tractor engines as tractors must of necessity work amidst clouds of abrasive particles. The device washes the air by drawing it into the air-washer through a tube and a partial vacuum is created at the lower point of the tube due to its U shape. Water enters the tube at this point in the form of a spray and commingles with the air. The tube is comparatively thin and wide, so that the air currents are subject to the water spray. This mixture leaving the tube is forced to impinge against a plate and as the velocity of the air at this point is rather low, part of the water drops down from this plate through the air stream thus again bringing the air and water into contact. The air then passes upward to the upper separating chamber where, by means of reduction of velocity and baffle plates which are placed there, moisture is deposited and the air passes to the carburetor. The water together with dust particles drops back to the lower chamber. The air-washer is connected to the motor.—By *B. F. Mundorff.*

## A Four-in-One Trouble Locater

IT is well recognized that most of the time required to locate grounds, shorts and crosses in electrical wiring, motors, generators and appliances by the present crude and wasteful methods is consumed in cutting, disconnecting, reconnecting, splicing, soldering, taping and tagging the wires and leads.

In order to save the repairman practically all of this waste of time and labor, and at the same time supply him with several other indispensable instruments, there has been developed the combination instrument here illustrated.

With it the inventor claims that grounds, shorts and crosses in wiring can be quickly and accurately located without cutting or disconnecting a single wire; and in a motor or dynamo the instrument will show whether the fault is in the terminal-block, the brush-holders, the commutator, the armature coils, or the field coils; also in which commutator segment, on which end of segment, in which field coil, and at which end of coil if near the leads. All this can be done without disturbing a single connection. Grounds inside iron conduit or steel-armored cable can also be located without cutting the wires.

The instrument for this kind of service is used like an exploring-coil when remote from strong magnetic fields, and as an alternating-current galvanometer when near coils or heavy currents.

As an explorer, or current-detector, the instrument is claimed to be considerably more sensitive to small currents of standard lighting frequency than the small commercial and home-made exploring-coils. Furthermore, its indications are visual, and therefore unaffected by noise that would in many cases seriously interfere with the use of a coil.

As an alternating-current galvanometer, the voltage drop in a No. 10 wire with only one ampere flowing can be detected between points less than two inches apart. This is equal to the performance of many millivolt meters.

Additional uses as a detector are to tell alternating-current from direct-current circuits, locating broken-down enclosed arresters, locating idle transformers—due to blown fuses—in multiple or polyphase groups without pulling a fuse and estimating the values of currents too small to be judged by the spark.

As shown in the illustration there are incorporated in the device a four-in-one combination instrument—a polarity indicator that does not have to be connected into the circuit tested; a compass with improved patented features that can be used in any position; a frequency meter with a range equal to a standard instrument; and an alternating current detector.—By *C. W. Eisemann.*

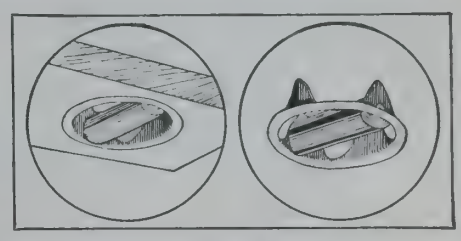
**Front and rear views of an electric explorer that does great work in locating trouble**

## Curious Cardboard Spectacles

SOME very curious optical effects can be secured with cardboard spectacles cut with various openings. The spectacles are easily formed in this way. Disks of cardboard are cut which measure about two inches in diameter. From copper wire a nose piece is bent as can be seen in the diagram. Each end of this is twisted into a hole made at the side of the disk. In the same way the bows for the ears are formed out of wire. One end of each of these is attached to the edge of the cardboard disk and the other is bent round so that the curved part for going over the ear is formed.

The disks of the spectacles are treated in this way. In one pair a hole is driven with a pin right through the center of each. With another horizontal slits are cut almost from one side to the other of the disks. These should be narrow and they may be cut with a sharp chisel or a penknife. In the case of the other spectacles the slit is of the same nature save that it is cut vertically on the disk.

When wearing the various spectacles some remarkable results are secured. Thus the pair with the pinholes restricts the field of vision but makes distant objects stand up with great clearness. It is possible to read print at three or four times the normal distance with the greatest ease. When wearing the spectacles with the horizontal slits it is only possible to see more or less horizontal lines in houses, fences, trees, etc., really plainly. Thus, while the trunk of a tree is difficult to detect, the horizontal branches are much sharper than is normally the case. Exactly the opposite is the case with the spectacles having the vertical openings. Here it is only the more or less upright lines that are really plain. The horizontal lines are very indistinct and if fine disappear altogether. Thus while one can observe the posts supporting the clothes line it is not possible to see the line itself when wearing the spectacles with the vertical slits.—By *S. Leonard Bastin.*



**Roller bearing for heavy furniture, showing attachment and operation**

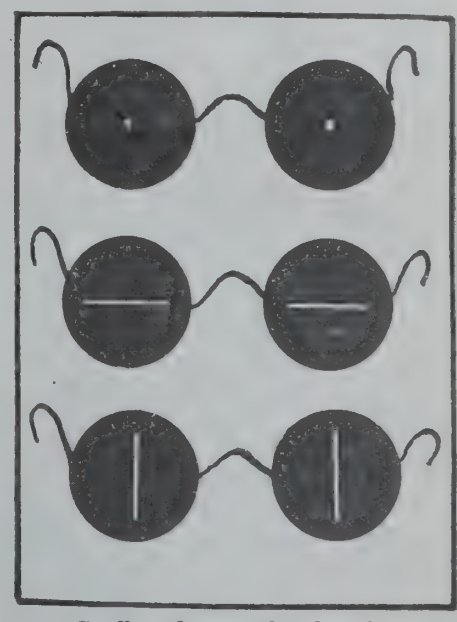
## The Jam-less Drawer

A NEW anti-friction roller for furniture that has sliding parts is a simple steel contrivance with a cylindrical steel roller which sets in a circular frame that fits perfectly into a ⅝-inch auger hole and has a flange that holds the roller 1/16 inch above the surface. The device is designed for use as a bearing for dresser drawers, extension tables, and other articles of furniture that frequently cause trouble and give annoyance because of a tendency to stick.

## Stainless Steel Kitchenware

TO produce a stainless steel that could be comparatively easily worked and could be used in the manufacture of other articles became the task of metallurgists, and after many experiments they discovered the accurate heat treatment at which it became more workable, and the evolution of many new pots and pans has been the result. The production of this steel is being undertaken in large quantities by all the progressive steel makers in Sheffield, and rustless cooking dishes will soon be on the market. These stainless domestic utensils will have a perpetual appearance of burnished steel no matter what usage they are put to. They may be cleaned by simply being washed in boiling water. They will not readily scale like iron, and their bottoms will therefore not get thin.

The new rustless steel will also be invaluable to engineers and can be used for the manufacture of bolt heads and for similar purposes where resistance to the atmosphere is desired. Engineers are even inquiring into its use for structural purposes, such as for bridges, the necessity of painting which entails enormous and continuous expense.



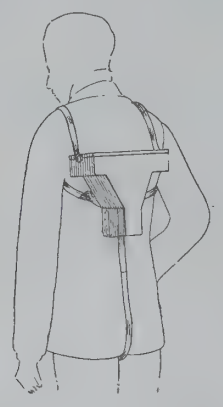
**Cardboard spectacles that give strange results**

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farming Implements, Etc.*

### Pertaining to Aeronautics

LIFE SAVING DEVICE.—J. SEBETO, 553 6th Ave., Brooklyn, N. Y. The invention relates to a parachute attachment to be strapped to aviators and passengers on aircraft for use in an emergency. The general object is to provide an attachment in which a parachute is held in compact form in a container adapted to be



A REAR PERSPECTIVE VIEW OF THE DEVICE AS STRAPPED TO THE USER

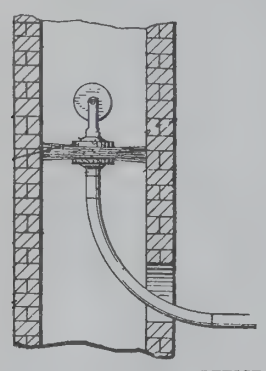
securely strapped to the body of an aviator and in a manner that the parachute may be caused to be automatically and instantly ejected from the container and caused to spread when ejected.

### Electrical Devices

ELECTRIC SWITCH.—W. D. THROOP, 198 Laurel Hill, Norwich, Conn. An object of the invention is to provide a quick acting switch operated by a laterally movable or slide member and which can be utilized for higher currents. A further object is to provide a switch which can be manufactured at an extremely low price, which is strong and durable in use.

### Of General Interest

CONDUIT CLEANER.—E. HALL, 3974 Scott St., Calumet, Mich. The invention has for its object to provide a device of the character specified, adapted for cleaning pipes of any character, as for instance, flues, drains, and the like, wherein a flexible shaft is provided



A SIDE VIEW SHOWING THE DEVICE IN USE

with a circular brush connected to the shaft to rotate therewith, the shaft having a guiding wheel for properly spacing the brush with respect to the flue and for facilitating the insertion and passage of the brush.

### Hardware and Tools

AX.—C. J. KOPRIVA, address A. F. Kopriva, Stony Brook, N. Y. The object of the invention is to provide an ax having an ax head and a removable bit to permit of conveniently and quickly removing a worn out or broken bit from the ax head and to replace such bit with a new one. Another object is to draw the bit securely and accurately into final position on the ax head and to hold the bit in this position against lateral displacement.

### Machines and Mechanical Devices

TYPEWRITING MACHINE.—P. ROBLE, address M. Davilla, 644 Carrera 7a. Bogota, Columbia. Among the objects of the invention are to provide a power-driven machine for automatically and serially printing a group of letters and automatically shifting the lines to be printed, to provide means for augmenting and limiting the marginal width of sheets on which the printing is to be executed, to provide a platen whereon paper is arranged for affording increased facilities for proof reading the printed matter prior to disturbing its relation to the printing mechanism, and to provide means for automatically shifting the line-printing thus avoiding interruption of the manual manipulation of the key board.

### Musical Devices

HOLDER FOR DISK RECORDS.—F. GRAMMICH, 499 Vandervoort Ave., Brooklyn, N. Y. The general object of the invention is to provide a holder formed of rigid material in the form of a case or container and so arranged as to accommodate a reasonable number of records that may be given back support after the manner of an easel to promote the accessibility of the records and their convenient handling.

### Prime Movers and Their Accessories

EXPELLING PIN.—D. J. BELL, 8 Main St., Salamanaca, N. Y. The invention more particularly relates to a tool for removing piston rods from crossheads of an engine. A further object is to provide a substantially heavy pin fitted with an expeller key, which pin may be inserted in the wrist pin bearing of a crosshead and operated to drive the piston rod from its seated position in said crosshead.

### Railways and Their Accessories

AUTOMATIC COUPLING FOR FLUID CONDUCTING PIPES OF RAILWAY CARS.—S. A. ROUSSEAU, De Witt, Ark. The invention relates to couplings in railway cars for fluid-conducting pipes, as for instance, air, water (hot or cold), or steam; the object is to provide mechanism which will connect the pipes when the cars are coupled, and will open the valves which are used to close the pipes when uncoupled, and which when the cars are uncoupled will close the valves to shut off the passage of the fluid.

### Pertaining to Recreation

AMUSEMENT DEVICE.—J. J. STOCK, 81 W. 101st St., New York, N. Y. This invention contemplates the provision of a tub which shall be capable of movement in a forward or rearward direction, rotation in a clockwise or anti-clockwise direction, or pivoting around one point of its circumference or around a diametrically opposite part of its circumference. A further object is the provision of a tub which shall not be in the least dependent upon the action of an outside machine, but which shall be entirely self-contained, even with regard to its supply of current utilized for operating its power plant.

### Pertaining to Vehicles

TIRE FILLER AND TESTER.—C. W. PELTON and J. P. BARBOUR, 215-17 So. Main St., Livingston, Mont. The invention particularly relates to filling and testing automobile tires. An object is to provide a tire air chuck and gage holder combined in one device which when connected with a source of compressed air will deliver the air into the interior of the tire or will cut off the air from the tire and put the latter in communication with the tire gage that the pressure may be readily ascertained; the device is operated by a slight manual movement.

### Designs

DESIGN FOR A BUTTON.—J. R. BELLIS, c/o Searing & Moore Co., 24 Beaver St., New York, N. Y.

DESIGN FOR A MEDAL.—A. de LAUTREPPE and H. M. MESRINES, 101 W. 109th St., New York, N. Y.

DESIGN FOR A POWDER CAN OR SIMILAR RECEPTACLE.—C. S. HUMPHREY, c/o Manhattan Can Co., Bush Terminal No. 10, Brooklyn, N. Y.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## The Last Word in Wireless—The New York Radio Central Station

*(Continued from page 79)*

machine is to be duplicated and installed in the New York Radio Central Station; but this time there will be two 200-kilowatt machines for each transmitting station—ten in all. The achievement, from a radio engineering standpoint, has nothing approaching a parallel: ten alternators, 2,000 kilowatts, 3,000 horse-power—an astounding force to concentrate in realization of a dream to transmit messages over the world to all points of the compass from a single source.

Mr. Nally emphasized another forward step in engineering which will be incorporated in the super-station. "We will utilize what is termed a multiple tuned antenna, which," he explained, "materially reduces the wasteful electrical resistance of the long, low, flat-top aerials formerly used. A great saving in power is thus effected; in fact, for the same power input formerly used for a single station, six times the effectiveness at a distance is obtained. In other words, we obtain with this antenna the same effect at a distance with 200 kilowatts input as would be obtained from the old type of antenna with 1,200 kilowatts input! This new type of antenna is the equivalent of six independent radiators, all operating in unison at the same wave length, and for the complete station with its five antenna units, the power required will be less than 20 per cent of that formerly necessary. The project, however, contemplates additional possibilities. To illustrate: We may, in many cases, utilize but one-half of a single spoke of the antenna system for communication service to a certain point. On this basis, the Long Island Station will ultimately permit simultaneous transmissions to a maximum of ten points in the world, thus doubling the communication facilities originally planned.

"The receiving aerials are of a new type, too; they have been designed for operation with the Weagant system of 'static' elimination, which, by a combination of opposed electrical circuits, nullifies the long-dreaded effects of atmospheric electricity and makes possible uninterrupted reception from foreign countries under all weather conditions. We break away from a precedent once again in locating our receiving units only eighteen miles from the multiplex transmitting equipment instead of following the former practise of establishing one transmitter and one receiver in one locality and restricting the service of the circuit to one overseas destination."

The arrangements for distant control of the New York Radio Central Station follow the same policy of concentration. In Broad Street, the heart of New York's financial district, the company's public telegraph office is being re-equipped to handle the new station's messages along with the Marconigrams which are now received for England, Norway, Hawaii, and Japan. Thus messages for any of the five additional countries reached by the new station will be received in the New York City office and dispatched direct from a series of operators' keys and relays which will operate the powerful transmitting circuits located miles away out on Long Island. Messages from over the ocean will ultimately be received in the same manner, receipt and delivery of the actual messages being effected by the customary messenger boy service direct to the home or office of the user of the trans-oceanic wireless.

It is expected eventually to install apparatus for high speed transmission and reception, which will be under the supervision of a trained staff of operators along with which there will be the usual staff of expert Morse operators who will work those circuits over which high speed transmission is not taking place.

## Descendants of the Water-Wheel

*(Continued from page 82)*

revolutions per minute, it is estimated that the frictional loss will be about 21 horse-power, which is a very moderate percentage of 42,500 horse-power. The shaft, it will be noted, varies in diameter. At the center of the rotor spider, the diameter is 26 inches. At the location of the thrust bearing it diminishes to 18 inches. The flanges which afford the means of uniting the two parts of the shaft into a single piece are 45 inches in diameter. They are, it appears, forged on to the respective shaft lengths.

It might be thought that the provisions for supplying the air necessary to keep the generator cool would not require much attention. But this would be a mistake. Somewhere in the neighborhood of 80,000 cubic feet of air is required to be passed through this generator every minute that it is operating at capacity. Air is obtained from above and also from the pit below. It passes over the windings and through the center core, and is then discharged into the casing which encircles the stator yoke. It then passes into ducts and by means of auxiliary fans is made to discharge itself outside the station. On top and bottom of the rotor steel plate, centrifugal fans are arranged. In addition to the circulating effect thus produced, is the action due to the poles and the ventilating openings between poles in the rotor rim.

What is perhaps the most powerful high-head, inward flow unit in the world is one which has been installed in the White River plant near Sumner, Wash. Its capacity is rated at 25,000 horse-power. The head is 440 feet and capacity speed 360 revolutions per minute. The unit is a horizontal turbine. That is, the shaft is horizontal, and the conduit which pours water from its inner side through the stationary vanes into the rotating device is arranged in a vertical plane. However, the conduit diminishes in diameter as it circles round, just as in the case of a vertical unit. In the present case the runner is of the double type. That is, it is equivalent to two single runners placed back to back and operated as a single unit. There are two points where the water escapes from the double runner—one to the right and the other to the left. This conduit diminishes in diameter as it rises in front and continues on over to the back. By this arrangement of the conduit, the greater amount of water passes under the runner and the lesser amount over it. Gravitation is thus opposed to good advantage.

While this unit is fairly large, it is by no means so big as the one we have been considering, even comparatively. The horse-power capacity of the horizontal unit is only 23 per cent less than that of the vertical one. It is the high head which enables a big output of power to be realized with a moderate-sized, compact unit.

The problem presented by the conditions of conservation at the White River plant required that the heavy fluctuations in the electric load should be responded to effectively by the water-power system. In short, the water supply giving the high head was adequate to high productiveness of current only in case it was wisely used. The White River supplies the operating water. It derives its supply largely from one of the glaciers on Mt. Rainier. The water after being dammed is led through a heavy wooden flume into a forebay, where it drops its glacial silt. The deposits of silt in the forebay are got rid of by flushing and draining. From the forebay the water is conducted to the reservoir at Lake Tapps. This consists of a natural lake whose water level has been raised some 35 feet. Deepened and enlarged, the lake has a storage capacity of some 2,250,000,000 cubic feet.

IN the bearings sponsored by S K F its type of antifriction bearings have been developed to their highest perfection. And S K F further provides an engineering service not only to assume to itself proper application and use of S K F products but to help the buyer to fully capitalize the mechanical value built into each device. This service is freely offered and is being continually broadened and advanced by laboratory research that is international in scope. You are assured a similar service behind every product bearing the mark—

SKF

*Among the S K F products now offered are:*

Single row deep groove ball bearings.
Double row self aligning ball bearings.
Steel balls.
Transmission equipment.

## Descendants of the Water-Wheel

(*Continued from page 92*)

As this is at an effective elevation of 440 feet above the power plant, it is estimated to represent in electric current about 18,000,000 kilowatt-hours. The water is brought down from Lake Tapps part of the way through a deep open cut and a 3,000-foot tunnel. The cross-section of this tunnel is such as to pass water at the rate of 3,000 second-feet. From the forebay at the lower end of the tunnel, steel pipe-lines carry the water down to the power house. These pipe lines are each about half a mile long and 8 feet in diameter. Sudden changes of the flow of the water through the tunnel and the pipe lines, particularly the latter, might be expected to develop violent variations in the pressures exerted from within outward. Some of the devices employed to meet the requirements are as follows. A surge reservoir was provided at the lower end of the tunnel to prevent surges, due to the tunnel, from causing violent effects in the pipe lines, etc. Then pressure regulators were installed in connection with the turbines of such sort that they release water suddenly when the governor abruptly closes the gates which admit water to the turbines. In order to make the plant responsive to sudden demands for power, air-cushion tanks have been installed. These react quickly upon demand, though naturally they can last for only a short time.

## Fifteen Thousand Photographs per Second

(*Continued from page 83*)

tures, one centimeter high, are received on the film, each picture will pose 1/5,000 of a second. Five millimeter views will pose 1/10,000 of a second, and so on. At that speed, the action of daylight is negligible.

We have already seen that M. Bull's installation gives a photographic field of 40 centimeters, same being the width of the luminous pencil. At the initial speed of 200 meters per second, a projectile passes through it in 1/500 of a second and by photographing same each 5/1,000 of a second, ten views can be obtained. It is absolutely necessary that all the various parts of the system work very closely together. As it would be useless to expect an absolute simultaneous action, the shutter must be opened and the series of sparks begun before the moment when the projectile enters in the luminous pencil. The interval should be reduced to the minimum, however, for two reasons: To avoid daylight touching the film for any length of time; and in order not to waste uselessly the loaded condenser which supplies a limited number of sparks, and on the other hand, to prevent the film, which continues to revolve, from being impressed a second time, which would blur the picture. It is therefore necessary to stop the sparks and shut the shutter as soon as the projectile has crossed the photographic field.

These various conditions are attained by means of electric control. The tumbler (or sear) which moves the striking lock of the cannon puts on a contact which opens the shutter during the inflaming of the powder. Another contact, which is caused by the "kick" of the gun, closes the circuit which unites the condenser to the exploding device and the sparks begin immediately. The motor is put in motion at about the same time as the shutter opens.

On a wooden frame placed in the firing axis, several centimeters outside the field, two threads (or wires) are stretched. These threads are cut by the projectile and one of them stops the sparks while the other closes the shutter.

With the electric device we have just described, M. Abraham has obtained 80,000 sparks per second and M. Bull might be able to obtain photographs at that speed, provided the film would move with the required speed. The posing period of each element of the film would always be the same since it corresponds to the time the spark lasts. It is impossible to foresee whether this enormous speed can be used in practice, but it seems probable that M. Bull will not find too many difficulties to exceed largely the rate of 15,000 photographs per second.

## Some Observations on Eggs

(*Continued from page 85*)

field, was flooded out during an early June irrigation. There were six eggs in the nest, which the farm children replaced as soon as the water was absorbed. They hoped that the meadow lark would return to the nest.

But the mother bird didn't. After a few excited outcries, as she discovered the irrigation water inundating her, she flew away. The next day the children discovered her building a second nest high and dry on a ditch bank, and a few days later the second nest was supplied with its full complement of eggs.

This meadow lark did what all wild birds do when a nest is robbed or destroyed. In the egg organs of the bird during the hatching season are a large number of undeveloped eggs. The bird ordinarily lays only the regular clutch, one egg to twenty, varying with different birds. However, if a nest is robbed or destroyed, the female bird will immediately proceed to produce more eggs to supply the deficiency. The possibilities in this unnatural stimulation are somewhat undetermined among wild birds, but that the egg-laying faculty is much greater than is generally supposed some authenticated instances show. There is the substantiated case of a flicker, one of the larger woodpeckers, a variety which ordinarily lays a small clutch. The nest of this bird was systematically robbed from day to day, and thus stimulated the female produced 71 eggs in 73 days.

In the light of this faculty, possessed by all wild birds, it is easy to comprehend how the domestic fowl was developed into the great egg layer she now is. Originally, it is fair to presume, wild chickens were simply confined, and their eggs regularly removed. In the course of centuries, as this treatment was continued, egg-laying became more and more a fixed characteristic. In most breeds, poultrykeepers still have to contend with broodiness, a desire to hatch out eggs, which seizes the hen several times in the course of the year. When the hen becomes broody, poultrykeepers "break her up," and if she is a good layer she is soon producing eggs again.

Development of egg-laying in the lightweight breeds, particularly the White Leghorn, has resulted in the practical elimination of broodiness. With the average White Leghorn flock, hatching can only efficiently be accomplished by using broody hens of other breeds or an incubator. It is not practical to attempt to hatch eggs with a young white Leghorn. Few become broody, and those which do are very uncertain setters.

Potentially all our wild birds are egg-layers. In taking the chicken and developing it into the egg machine it now is, mankind probably used the wild bird best adapted to the purpose—which goes further to show that even the farmer's scientific "hunches" are apt to be correct.

## Uncle Samuel's Sweet Tooth

(*Continued from page 88*)

thick molasses and beaten until it becomes the creamy filling with which we are all familiar. The sugar and water are cooked in a big kettle and then drawn up into a cooling tank by vacuum. The stuff then passes through water-cooled pipes and drips to a motor-driven beater, which delivers the fondant to vats mounted on hand trucks.

All good amateur candy makers know that flavoring should be added after the cooking and this is done here. The fondant is taken to steam-heated tables, which keep it soft, and flavoring, nuts and the like are added and the mixture "kneaded" into the candy by the workman. The fondant is then shaped, either by machinery or by hand, according to the quality, and is dipped in chocolate. If the dipping is to be done by hand the fondant passes to girls, each of whom has a puddle of soft chocolate at her side, which she constantly stirs with one hand, while she dips the chocolates with the other. As her hand leaves the finished piece, she draws up a tail of the chocolate and bends it back over the piece, giving the "finish" with which we are all familiar. The chocolates are left to dry on small squares of embossed waxed paper, so that when they are removed the maker's name has been impressed in the bottom.

If the chocolates are to be dipped by machine, girls arrange the fillings on an endless belt, which carries them to the machine. Here they are transferred to a belt of wire rods and are carried through a slow-moving stream of molten chocolate. The excess chocolate drains off through the belt and is carried again to the top of the machine, where it is remixed and again passes through the belt. As the chocolates pass out the other side of the machine, they are again transferred to an endless belt. Two girls seated at this side of the machine dip their fingers in chocolate and add the "finish" of hand-made chocolates. The belt carries the candies through a slot in the wall to the next room, where the air is so conditioned that they rapidly dry. Girls remove them from the belt and they are then ready for packing.

Many of the hard candies are molded by a process very similar to that used in a foundry. The molds are made of starch, into which a pattern has been pressed. The candy is run into the molds from vats, which are steam-heated to keep the candy soft.

In making the familiar hard candy "pillows" the candy is molded into long strips, is run through a heater to soften it and then is cut by passing it between the teeth of two especially made gears. Caramel and nougat cubes are produced by making the candy into slabs and cutting it on a machine which has much the appearance of a buzz saw. The "saw" however is a revolving knife.

The machinery of the candy factory also reveals the secret of making "Jordan almonds." The nuts are placed in a revolving drum about the shape and size of a cement mixer. As this revolves the candy is admitted and the nuts gradually become coated evenly with the delicately flavored hard candy.

Each kind of candy really requires special process and machines and a little department all its own, so it will be seen that a very large output is essential to economical manufacture. The troubles of the maker are complicated by the fact that the demand for candy is seasonal. Thus, we buy and eat nearly as much candy during the months of October, November and December as in all the rest of the year. This problem is met by the maker of cheap candies by producing candies of a kind that will keep well and storing them for the busy season. The maker of expensive candies must sell his product quickly, however, because his goods become "stale" and unsalable within a short time. He can only meet the difficulty by hiring many workers in the busy months and reducing his force during the rest of the year.

Present high prices, which might be thought to cause a reduction in the demand for candy, are having the opposite effect, candy makers say. We are consuming more candy today than ever before in history.

## Going to Sea in a Tank

*(Continued from page 90)*

of 3 inches; and this play gives the operator the needful leeway in adjusting the speed of the carriage to that of the model—his object being to keep the guide plates clear of the limiting stops. If the guide plates strike the stops, owing to the model and the carriage getting out of pace, then the run does not count.

A series of runs consists of a score or more trips the length of the tank at increasing speeds; and from the data so obtained are plotted curves showing the torque, the thrust, and the revolutions per minute at the several velocities. All models at Washington are 20 feet in length, and, according to the size and character of the proposed vessel, these miniatures have a dead weight of a ton or more. The single-screw models tried out in 1918 had a maximum displacement of 3,774 pounds.

After the self-propulsion tests are made, it is the custom to remove the propeller, and then the motor or motors are driven so as to get readings of the shaft friction and the amount of thrust in the absence of the screw or screws. The next step consists in attaching the model to the towing carriage, and in establishing, by successive runs, resistance data peculiar to the model and independent of the propeller. It is important that these runs be carried out with the model in the same condition as when self-propelled and, also, that the temperature of the water be substantially identical in both series. It seems that investigators have discovered that resistance may be increased as much as 4 per cent for each lowered 10 degrees of temperature of the water, and lessened by each corresponding rise of 10 degrees.

Facts about the characteristics of different designs of screws are secured by testing them apart from the model by runs in the tank. For this purpose there is a special equipment carrying a projecting propeller shaft well forward of the supporting structure so that the screw actually turns in undisturbed water—moving ahead of the driving apparatus. The result of the present method is, therefore, that the screw and the model can be subjected to examination independently and then tried out in combination.

Much added knowledge has been garnered having to do with the efficiency of the propeller agreeably to the surface condition of its blades; and we know today how the screw is affected by the shape of the model and by the state in which the water arrives within the zone of action of the propeller. All of this mass of information is important and bears directly upon the capability of our new-born merchant marine to hold its own in competition with the ships of other nations. The cost of fuel has reached a point where every pound saved in realizing a given sustained sea-speed is of economic moment; and the self-propelled model is aiding us to determine vital facts about a prospective craft's operative charges. We can build ocean-going freighters confidently and be certain that they will maintain their prescribed speeds when burning less coal or oil than many another rival steamer of similar cargo-carrying capacity.

## Explosives from Sugar

SOME particulars were recently communicated to the German Chemical Society regarding the process developed during the war by the production of explosives from sugar.

Glycerine was produced from the sugar, the former being used as the initial product for trinitro-glycerine. The process, invented by Connstein and Ludecka, is based on the fermentation of sugar. It was already known that sugar, when fermented, produced minute quantities of glycerine. The inventors found that the

CONNECTICUT IGNITION

SIMPLY PUSH THE BUTTON WHEN YOU WANT TO START AGAIN

How the Automatic Switch Insures Your Ignition

You forget to turn off your ignition often enough to create a real danger to the system; but forgetting makes no difference to the Connecticut system. When the motor stops the continued flow fo the current heats the thermostatic arm of the Connecticut Automatic Switch, causing it to expand, throwing off the plunger and breaking the circuit.

This thermostatic arm is composed of bronze welded to steel. The bronze expands more rapidly under heat than the steel, and this uneven expansion *automatically* snaps off the plunger, stopping the flow of current immediately.

It is a simple mechanism, infallible in operation, and requires neither thought nor attention—except to push the plunger back when you want to start again.

The automatic switch thus permanently protects both coil and battery. Therefore the Connecticut system, free to deliver full current, furnishes a hot, fat, eager spark at all motor speeds.

It should be on the next car you buy.

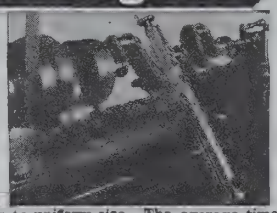
**Weber Crank-Pin Re-Turning Tool**

**No Filing**
**No Offsetting**
**No Jigs**



This Weber Tool turns all pins absolutely round from one setting of Crank Shaft, on centers. A micrometer dial enables the operator to gauge his cuts and turn all pins to uniform size. The average time required for trueing up one pin is from 5 to 10 minutes. The 4 pins can easily be finished in 30 minutes, and the entire shaft is completed with only one setting.

**The Weber Tool is guaranteed** to turn crank-pins within as close limits of accuracy as any other known method. It will soon save its cost in any Tractor or Automobile Repair Shop. An assortment of cutting tools are furnished. These will fit the pins of most of the popular automobiles, trucks and tractors. Write for Circular and Prices.

**Make Belt Joints That H-O-L-D**

A BELT JOINT once made with Crescent Belt Fasteners is made to STAY. Crescent Plates and Crescent Rivets take a won't-let-go grip on the belt. The heavy strain of long continuous service cannot loosen them. You eliminate once and for all the interruptions caused by breaking belt joints. Continuous production is insured. The Crescent joint maintains the full strength of the belt for the full life of the belt. Write Dept. 66 for new Booklet on Increasing Belting Efficiency.

CRESCENT BELT FASTENER CO., 381 4th Av., New York
Canadian Branch:
32 Front St., W., Toronto, Canada

percentage of glycerine obtained was considerably augmented by adding sodium sulphite to the fermenting bath. To a solution of 1 kilogram sugar in 1 litre of water they added 400 grams of sulphite, 10 per cent of the sugar being allowed to turn into yeast. They then made sure that the yeast cells were properly nourished or propagated. After two days the sugar had completely fermented. By suitably working up the liquid so obtained, a glycerine suitable for all technical purposes was obtained.

The process was organized by a company and carried out by 63 works. After a few difficulties were overcome, it was possible finally, from 100 parts of sugar, to obtain 20 parts of glycerine, together with 27 parts of alcohol and 3 parts of aldehyde. One works produced 1,000 tons. of glycerine a month, the annual consumption of sugar being 70,000 tons..—*Zeitschrift des Vereines deutscher Ingenieure* (Berlin), July 19, 1919.

## Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to Correspondents are printed from time to time and will be mailed on request. Please write your queries; do not telephone them, please.

(14332) N. B. asks: I have your book SCIENTIFIC AMERICAN Cyclopedia of Receipts, etc., published in 1892 and have used same with profit many times. It has now gone back on me. I wish to silver a piece of glass 7"x9" for use as a mirror, the silvering to be on the front of the glass instead of the back in order to get rid of the prismatic effect of reflections as seen in the ordinary mirror. I do not seem to find a formula suitable for this. Can you refer me to one in the book or send me one? A. You will find the Brashear process for silvering glass a most reliable one. It is now employed in silvering the large mirrors in the great telescopes. It is No. 10 on page 502 of the SCIENTIFIC AMERICAN Cyclopedia of Formulas. The Draper process is also reliable but is older than the Brashear process. Everything depends upon perfect cleanliness and most careful attention to every detail, else the work will be spotted and worthless.

(14333) H. R. B. asks: A contends that a vacuum exists and also that vacuum has the power to restrain or act as a nonconductor against such an energy as heat. Is he correct in his contention? A. A vacuum is the best insulator against heat which is attainable. A perfect vacuum would be a complete insulator and would retain or exclude heat indefinitely. The common thermos bottle is an example of the use of a vacuum for keeping liquids either hot or cold. Heat is retained in hot liquids and kept out of cold liquids. A is quite correct in his contention. However there is a difference between heat from a white hot body like the sun or an electric lamp and heat from a liquid or solid such as may be contained in a thermos bottle. The intense heat from a white hot body will pass easily through the best vacuum man can make, as witness the heat given off by an incandescent lamp bulb, which will char and set paper on fire. A vacuum will restrain heat of low intensity but not heat of high intensity.

(14334) S. M. R. asks: Kindly settle a dispute we are having in regard to an article contained in the SCIENTIFIC AMERICAN. "A" maintains that the water pumped from the copper mines if placed in a container and tin placed therein that the tin will be transformed into copper. Please be good enough to state whether it is possible by any method to transform tin or iron into copper. "A" claims that an article containing the above to have appeared in the SCIENTIFIC AMERICAN. A. There is no method known to chemists for changing copper to tin or tin to copper. If a copper deposit is made upon tin from water which has been pumped from a copper mine, it is because the water contains some salt of copper dissolved in it and this is by an electrical action decomposed and the copper is plated upon the tin or iron. This may very easily take place. A knife blade dipped into a solution of copper sulphate will in a few seconds become coated with a deposit of copper for the same reasn.

(14335) B. L. P. asks: During the month of September, 1918, I had the privilege of seeing a most wonderful phenomenon. I was compelled to lie out in the sunshine a certain portion of each day and necessarily wore black glasses. One morning, a day or so after a rainstorm, the sky became partially covered with swiftly moving, thin, fleecy clouds. I was turned toward the sun, but protected from its most direct rays by the corner of the roof. Looking at the clouds near the sun, I was startled to see them turning different colors. Thinking perhaps I was just seeing a rainbow on the clouds, I continued to look carefully. But no, the rainbow colors were there—beautiful, soft pastel shades of pink, green, blue, lavender, yellow, orange—*but they were not in rainbow formation nor did they appear in the same position twice.*

As the wind caught fragments of clouds, they became so many bits of color, weaving in an out, a veritable kaleidoscope of the heavens. There seemed to be no uniformity of color in reference to the position of the sun, except the clouds nearest the sun were usually a sort of apricot color. But the pinks and blues, green and lavenders all mixed together in a marvelous manner. To make sure I did not dream all this or imagine it, I had my mother and sister each lie in the same place and look through the dark glasses. They both saw the same coloring. Since then I have seen the same phenomenon, but always in the morning when the sky was clear except for these fleecy clouds, and always through dark glasses. Having spoken to a number of people about this, none of whom can explain it, I am writing to you, to see if any one else has had the same experience, or can explain the reason for the color separation. A. Your observation of clouds near the sun forming beautiful colors is very interesting. What you saw were bits of halos from the water drops or perhaps ice crystals of the clouds if the clouds were high enough above the earth to be composed of ice crystals. Halos are usually circles of colors like rainbows, but near the sun instead of on the opposite side of the sky from the sun, as a rainbow is. In your case the colors were in the clouds and not in the minute crystals of ice in the open sky. Otherwise the two seem to be similar.

(14336) G. S. DeH. asks: In a discussion with another man, who is of a scientific turn of mind, we came to a standstill in regard to the air pressure below sea level. We know that at sea level it is approximately 14.7 lbs. per sq. in. and we know that as we go up on a mountain top that the air pressure grows less. Now the question is, does air pressure grow less as one gets below sea level or does it get greater and if greater what would be the approximate pressure at the center of the earth, also is gravity strongest at sea level or does it increase as one nears the center of the earth? A. The air pressure increases below sea level in a mine shaft or drill hole down into the earth. At about 1,800 feet above the sea the pressure is one pound less than at sea level. The pressure decreases another pound by about 2,000 feet more of elevation. In an open hole like a mine, a drop of perhaps 1,600 feet below sea level would raise the pressure a pound to 15.7 pounds. The layers of air whose weight is one pound per square inch would become thinner as we descend into the earth. What the air pressure would be at the center of the earth we do not know. Air pressure is simply the weight of air resting on a square inch. On the other hand gravity is greatest at the earth's surface, and diminishes as one goes either above or below the earth's surface. The pressure of the rock and earth strata increases as we descend into the earth, just as the air pressure does, because the weight resting on a surface increases as we descend into the earth.

**Akron Quality Tires**
*REDUCE TIRE COST 65%*

1 Tube and 1 Tire FREE *Its in the Guarantee*

**4500-Mile Guarantee**

We car safely make this guarantee, as Akron Quality Tires are made of all selected material, are all wonderful bargains and will outwear any two rebuilt or vulcanized tires. Our written guarantee in every tire provides for a new tube and tire free if mileage is not given. These double fabric tires are built strong and substantial, long to wear and hard to puncture.

**The following prices for this month**

| Size | Tire | Tube |
|---|---|---|
| 30x3 | $ 6.50 | $2.00 |
| 30x3 1-2 | 6.50 | 2.10 |
| 32x3 1-2 S. S. only | 7.50 | 2.20 |
| 31x4 | 8.50 | 2.40 |
| 32x4 | 8.75 | 2.45 |
| 33x4 | 9.00 | 2.50 |
| 34x4 | 9.25 | 2.60 |
| 34x4 1-2 | 10.75 | 2.80 |
| 35x4 1-2 | 11.00 | 2.90 |
| 36x4 1-2 | 11.50 | 3.00 |
| 35x5 | 12.25 | 3.20 |
| 37x5 | 13.00 | 3.50 |

**Reliner Free With Every Tire**

State whether straight side or clincher desired. Send $2 deposit for each tire ordered and $1 for tube; balance C. O. D. subject to examination. If you send full amount with order, deduct 5 per cent discount.

Mail Order Dept. 50
**AKRON TIRE & RUBBER CO.**
2000 ROOSEVELT ROAD CHICAGO, ILL.

**Learn Autos & Tractors Earn $100 to $400 Per Month**

Qualify right away for a good paying job and bright future in the Auto and Tractor field. At our great school, under expert instruction, you can learn to operate, adjust and repair all makes of Autos, Tractors, Trucks and Gas Engines, including complete automotive electricity. Low tuition now. Work with actual tools. Write at once for particulars.

**FREE** A fine kit of 29 tools given to everyone who enrolls now. Send for free book. Get full information.
MILWAUKEE MOTOR SCHOOL
Dept. 756, 555 Downer Ave., Milwaukee, Wis.

**Cleartone Phonographs**

**$4.00 to $200.00 Retail**

Our Sundry Dept. offers Needles 39c per thousand. Motors $1.35 to $14.75 each. Tone-Arms and Reproducers $1.30 to $5.75 per set. Main Springs 20c to 90c each. Records, Needles, Sapphire Points and Parts at reasonable prices.

Write for our 84-page catalogue, the only one of its kind in America, illustrating 33 different styles of Talking Machines and over 500 different Phonographic Parts.

# The Most Work

*for*

# The Least Money

THE White idea has always been to build an economical truck. No detail has ever been changed which did not definitely improve its ability to do the most work for the least money.

White output grows as owners get more experience in judging truck values, and economy of manufacture grows with output. Today White output is largest in the high-grade field and White prices have increased a mere fraction of the average advance in truck prices during a five-year period.

Owners of White Trucks with mileage records of 100,000 to 300,000 miles *know* that White Trucks do the most work for the least money.

# Rainbow Wears Longest in Service

The true test of any sheet packing is how long it will last in service.

For over thirty years Rainbow has been the choice of engineers because of its longer wearing qualities.

For packing stationary or vibrating joints—with a saturated steam pressure up to 150 pounds and for all hydraulic pressure, Rainbow Packing will unfailingly outlast any other packing.

Be sure you get genuine Rainbow—with the diamond Trade Mark.

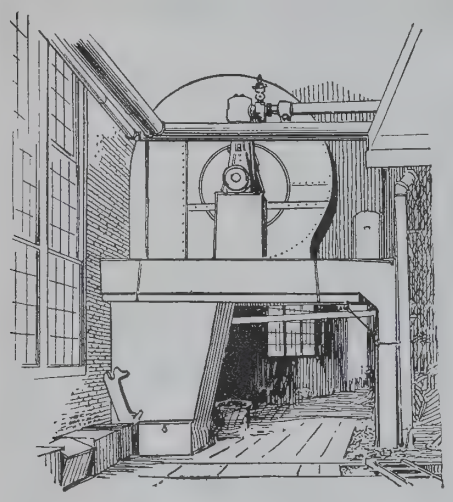
## PUTS AIR TO WORK

# There Are Dividends in the Air

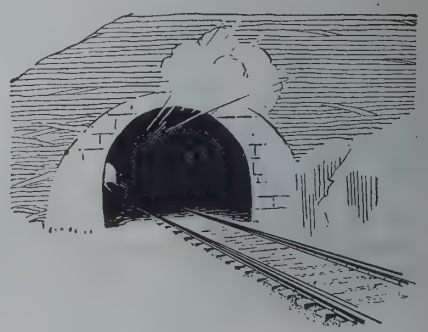
STEAM and electricity, when harnessed and put to work, will do man's work. They pull heavy trains, those shuttles of commerce that go roaring across the land. They weave into our national life profits and comforts undreamed of a century ago. Truly, steam and electricity are the wonders of the age. But no less wonderful is air, and what air, properly controlled, will do. It will do certain kinds of work more quickly, more efficiently, and more economically than any other known agent. Air will actually pay dividends.

### *Correct Heating and Ventilating of Railroad Roundhouses Pays Dividends*

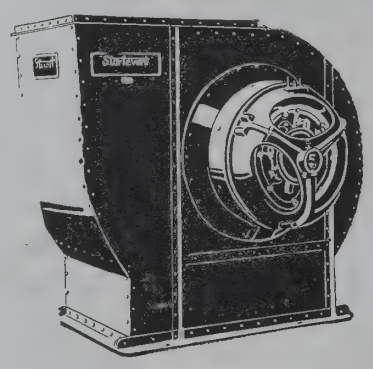
There was a time when ice-coated locomotives were thawed out by heat from steam coils. It took many hours to melt the heavy ice accumulations and to soften the congealed oil and grease. Dense clouds of vapor from the thawing moguls filled the roundhouse. Men could not see to work. Serious accidents were frequent; expensive delays to train schedules were many. An Eastern trunk line installed a Sturtevant Heating and Ventilating System. It solved three problems in this roundhouse—heat, ventilation, moisture absorption. Heated dry air driven by a Sturtevant Fan is carried around in underground ducts and brought into the engine pit. This hot, dry air thaws the ice and quickly carries away the moisture. Today heavily ice-encrusted locomotives can be thawed out in two hours and be on their way to earn dividends for the railroad.



### *How Sturtevant Apparatus Makes Railroad Tunnels Safe*



Positive ventilation of railroad tunnels is absolutely vital. In poorly ventilated tunnels, smoke and gas from the locomotive drift back into coaches and engine cab and often cause loss of life. Engine crews have been known to be asphyxiated by the smoke and poisonous gas fumes from their engines. Sturtevant has installed, in many tunnels throughout this country, highly efficient ventilation systems. By this system an induced draught of air at the portal of the tunnel travels ahead of the entering train. All smoke and gas are carried far ahead of the engine. Thus passengers and engine crew are free from the menace of dangerous gas. If the tunnel is on a grade, the ventilating system is shut off when the train comes down the grade; for there is little smoke and gas when the engine is coasting.



This is only one of the many ways Sturtevant puts air to work.

Your business may be paying dividends. Perhaps it could be made to pay still better if production costs could be lowered. Tell us about your processes. We shall be pleased to send a bulletin covering in detail the particular Sturtevant equipment that can put air to work for you. For three generations Sturtevant has been building apparatus that puts air to work. All the experience, both engineering and manufacturing, is at the command of its engineers. If you wish it, a Sturtevant representative will visit you at your plant. Address

1 The motor that drives the emergency pump. 2. The motor for the pump that handles the ordinary seepage. 3. Sump in which water collects, from which it is automatically pumped

**Part of the outfit that keeps the water down in the Queensboro Tunnel under the East River**

## Keeping the River Tunnel Dry

**By M. A. Henry**

WHAT would happen if one of the walls of the tubes under the Hudson River in New York should spring a leak?

The thought has probably occurred to every person who has passed through one of these great tunnels in a train. And then we promptly forget about it, for nothing of the sort apparently ever happens. But most of us will be surprised to learn that water from the river overhead is constantly seeping in and that scores of automatic sentinels stand guard day and night not alone to insure that this seepage shall be kept under proper control, but as well to guard against the disastrous possibility of an actual break in the tunnel wall which would admit the water in greater volume.

These sentinels are electric pumping stations located at intervals along the tunnels. They are entirely automatic and need only an occasional inspection to ascertain that everything is in working order.

Each pumping station consists of two main units, a small pump for taking care of the water which ordinarily drains into the tunnel, and a larger pump for emergencies. Both pumps are driven by electric motors and are controlled automatically. The water collects in a sump in which there are two float switches, one for each motor, and when the water rises to a predetermined point the float switch for the smaller motor closes. This energizes an automatic contactor which starts the pump. When the water in the sump is brought down to a proper level, the switch opens and stops the pump. But should the smaller pump be unable to handle the flow, the water continues to rise until the larger pump is automatically started through actuation of its float switch.

The photographs show a typical installation in the Queensboro Tubes, under the East River. The smaller motor is of two horse-power and it drives a reciprocating pump with a capacity of 50 gallons per minute. The emergency pump is driven by a 100-horse-power motor. It has a capacity of 1,000 gallons per minute. There are twenty-five such pumping stations in this tube. A noteworthy feature of this installation is that it occupies a floor space only 12 by 15 feet.

## Spontaneous Combustion Temperatures of Liquid Fuels

AN English engineer, named Mr. H. Moore, has recently been making a series of investigations which are of great importance with respect to the functioning of internal combustion motors, since they concern the temperature at which spontaneous ignition occurs in liquid combustibles. The results of these were recently presented by him in London before the Institute of Petroleum Technology.

Mr. Moore defines the temperature of spontaneous ignition as being that at which a substance surrounded by oxygen or air of the same temperature ignites without the aid of a spark or any other local elevation of temperature. To determine this point he has invented an apparatus which has the merits of being simple in structure and rapid and exact in operation. In this apparatus the liquid combustible to be tested is allowed to fall drop by drop into a hole, pierced in a block of heated steel, whose temperature can be controlled and determined with the utmost precision; at the same time there is admitted a current of air or of oxygen which has been previously heated. Mr. Moore has made an extensive study by means of this simple apparatus of varying conditions controlling the ignition points, such as the respective quantities of the combustible and of the oxygen utilized, dilution with carbonic anhydride, and the catalytic action of the metal of the test hole, finding that all these factors have but very slight effect.

The experimenter has formulated tables of the temperature of spontaneous ignition in air and oxygen of a large number of combustible substances, including crude petroleum, various products and residues of distillation, coal tars and distillates, schist oils, alcohol, and purely organic products. By a study of these tables he has been led to the following conclusion:

1. Among the distillation products of petroleum the lightest products possess the highest ignition points.

2. The same rule holds good for coal tar products, but all aromatic products possess ignition points higher than those of the products of the distillation of petroleum at a corresponding point of ebullition. Olefinic products such as the pyrogeneous essences ignite at a lower temperature than the corresponding saturated hydro-carbons.

3. The temperature at which spontaneous ignition takes place in oxygen is generally lower by from 100°C. to 170°C. than the temperature at which ignition occurs in the air.

Mr. Moore has likewise constructed a number of highly interesting curves illustrating the variation of the ignition points according to the proportions of various mixtures of possible substances such as gasoline (petrol) and benzol, and the essence of cannel-coal-creosote and has demonstrated that a small quantity of a component having a low ignition point exerts a very much greater influence than does a large proportion having a higher ignition point.—By *M. Tevis.*

## How Fast Can a Yacht Sail?

GENERALLY speaking, the speed of yachts is over-rated, and you may safely take from twenty to thirty per cent off when your friend tells you that his craft has done so and so. On the other hand, there are some well authenticated records of high speed made by racing yachts under favorable conditions, which show the best of them to be wonderful examples of the science and craft of shipbuilding. The maximum speed of a yacht, supposing that her model and the cut of her sails are correct, is dependent upon certain adventitious conditions, such as the right kind of wind, the sea, and (above all) the skipper. The ideal conditions for speed are when a yacht is reaching in a smooth sea with the wind over the quarter, that is well abaft the beam, and with everything set that she can carry without an excessive angle of heel.

A well-known authority, Major B. Heckstall-Smith, author of "The Complete Yachtsman," in answer to the question, "How fast can a racing yacht sail?" states that at full speed a racing schooner about 105 feet on the waterline can do about 15.8 knots. This would be in a strong breeze with the wind on the quarter. Assuming that this speed is about right, as he believes, he tells us that with exactly the same breeze, a 90-footer can go 14.2 knots; a 75-footer, 13.4 knots; a 60-footer, 12 knots; a 50-footer, 10.9 knots; a 36-footer, 9 knots; and a 20-foot boat, 7 knots.

Now as to verification of these surprisingly high rates of speed. Beginning with the big fellows, let us take the three-masted American schooner, "Atlantic," which won the Kaiser's Cup in the transatlantic races. The log of the yacht shows that during this race, the famous schooner averaged 14.2 knots for twenty-four hours in mid-Atlantic, and one occasion on Long Island Sound she made an even 16 knots in smooth water and a strong reaching breeze. The Watson, two-masted schooner, "Rainbow," 115 feet long, is quoted as having actually logged 16½ knots. The fastest speed that Heckstall-Smith ever measured with accuracy was when sailing on the 104-foot schooner "Germania," when she made an even 15 knots off the Isle of Wight.

Coming to the 90-footers, the same authority tells us that he was in an historic race, sailed in a gale of wind from Rothesay around Hilsa Craig and back, a distance of 75 miles—a close reach on the way out and broad coming back. The average speed of the winning 90-foot yawl "Sybarita" was 12.3 knots.

A much higher speed, unquestionably the fastest speed on record for a 90-foot yacht, is that given to us by William Butler Duncan. He tells us that in September, 1899, after the Herreshoff yacht, "Defender," had finished acting as trial horse for the "Columbia," he brought her down from New London to City Island, where she was to go out of commission. It was the last time this beautiful craft was under canvas, and as there was a 25- to 30-knot breeze which held true for the whole trip, Mr. Duncan laid a course sufficiently under the lee of Long Island to insure smooth water, and seized this opportunity to determine just what a racing 90-foot boat could do with a strong wind over the quarter. So he put her to the test with full mainsail, with a jib header above it, fore staysail, jib, and small jib topsail. The "Defender" left New London at 6:07 A. M., and reached City Island at 12:24. After making allowances for the tides, he found that the average speed for the whole 86 miles (knots) was 13.8 knots, and by patent log, the actual speed through the water for two hours was shown to be 14.5 knots, which agrees very well with Heckstall-Smith's estimated highest possible speed of 14.2 knots.

The other estimated maximum speeds could doubtless be verified by yachtsmen who have owned racing craft of the various lengths mentioned, although we think that 13.4 is a little high for a 75-footer. As to the smaller classes, the writer once sailed at 21-foot knockabout from Bridgeport to City Island in half a gale of wind. The course was laid under the lee of the New York shore. The wind was over the quarter and under storm jib and with all reefs in the mainsail, the little boat showed an average speed after tidal corrections had been made, of 7.2 knots.

## The Engineering Skeptic

ENGINEERING practice in its broadest sense covers the process of reasoning which leads us to seek any result whatever through a particular course of action. It is as much engineering practice when the naked savage shoots his arrow a little up the wind to allow for the inevitable deviation as when the modern bridge-builder calculates the load which his structure must bear and the dimensions which will enable it to bear it. And in this broadest sense of the term we may recognize that engineering practice has passed through several distinct periods.

On general grounds there are two fundamentally distinct viewpoints which may be held by the man who approaches a task. He may attempt in some way to predict the result of attacking his task in this way or that way or the other way, and on the basis of such prediction to select the most advantageous procedure; or he may assume at the start that such prediction is futile, and work out his own salvation through a process of trials repeated until an acceptable procedure is revealed. An offhand opinion of almost any intelligent observer would doubtless be that the second-named method is the one originally employed by the primitive engineer, and that the progress of civilization might fairly be marked by the extent to which the process of performance based on prediction has supplanted the crude method of try-it-and-see.

The fact is, however, that there has been a certain swinging of the pendulum between these two procedures. The Greeks, with their supreme contempt for any disconcerting facts which might operate to bankrupt a pleasing theory, assumed that things would work the way a man with an artistic temperament would like to see them work; and in one way or another, they managed to "get away" with this philosophy. After the decay of Greek thought, the world was for many centuries very largely dominated by the try-it-and-see school of thought—people tacitly admitted that they didn't know much about anything, and that the way to find out whether a plan would work was to try it out. The world was kept from complete adherence to this way of doing things by a child-like confidence in the surviving fragments of Greek knowledge and dogma; but in the main the Middle Ages answered practical questions by trial. That their trial was not always an intelligent one, as when they determined guilt by the ordeal, does not touch our argument.

As the modern scientific viewpoint came into being, however, it was realized that valid general inferences might be drawn from specific instances. This led to the formula, deduced from experience and experiment and applied in advance to tasks to be undertaken. The child-like faith of the Greeks in the ability of the human mind to reason out all things on a basis of beauty of thought was replaced by an equally child-like faith in the universal applicability of the formula.

Today engineers are swinging well in the other direction. It is recognized that while the laws of cause and effect are universal, they apply to human affairs theoretically rather than practically. If we apply the formula too freely we shall presently catch ourselves applying it blindly in circumstances that are not exactly parallel; for circumstances are seldom identical, and we can seldom know to what extent and in what manner they differ. And this heads us straight toward disaster, as the many failures of engineering undertakings which seemed on solid ground demonstrate.

So today we still predict by the aid of formulas, and we use in fact more formulas and more complicated formulas and more precise formulas than ever before; but we bring to the aid of the formula an auxiliary, a far less expensive method of try-it-and-see than is involved in the failure of a complete machine to function, or the collapse of a Quebec bridge. Wherever possible we have tests and tests and then more tests, on a full scale or a miniature scale or any scale that is practical; and it is only when by this means we have made as absolutely certain as is possible that the formulas we have applied to the problem in hand are really applicable to that problem, that we proceed to the decisive step of final performance. So in a very large and fine way, the present has become again the age of engineering by trial and error—trial and error directed toward the intelligent control of intelligent prediction.

## Oil Firing in the Atlantic Service

IT is a serious matter to make any radical change in the motive power of the great transatlantic liners, after they have once entered the service. Such ships as the "Olympic," "Leviathan," "Imperator" and "Aquitania" would cost to construct today from fifteen to twenty million dollars, and how expensive it is in these days to do any extended refitting is shown by the estimates of cost, recently made public, of the proposed change of the "Leviathan" from a coal-burning to an oil-burning ship. The fact that the owners of the "Olympic" and the "Aquitania" did not hesitate to withdraw these great ships from service for several months, at a time when they could have been filled to the limit on every trip to Europe, and their willingness to go to the great expense of fitting them with oil-burning equipment, shows how great must be the economic and the other collateral advantages of oil burning in passenger ships of this magnitude.

The "Aquitania" and the "Olympic" can take on 6,000 tons of oil fuel in six hours, as against the four days which were necessary for taking on coal. The latter operation, as everyone knows, is a noisy and altogether dusty and dirty job; the re-fueling of an oil-burning ship on the other hand is a mere matter of hose connections and is altogether silent and cleanly.

One of the most valuable advantages of the change is its effect upon the labor question on shipboard. The number of firemen, which on the largest liners ran into several hundred for coal operation, has been reduced by over seventy per cent, and in the "Aquitania" there will be but four firemen on each watch. There is the added advantage that the total power developed at the boilers is under the direct control of the engineer. In the "Aquitania" there are no less than 168 furnaces; and everyone knows that there is a drop in the steam pressure every watch during the cleaning of the fires. If it be assumed that 28 out of the 168 furnaces are cleaned every watch, it means that about 8,000 horsepower is lost every four hours.

Now, with oil-fired boilers there is no such thing as clogging up of the grate bars by clinkers, and consequently there is no letting down of the steam due to cleaning operations. Once the burners have been started, the temperature of the furnace can be maintained with great regularity. The large reduction in the boiler-room force, coupled with the better-regulated combustion of the fuel, combine to produce great economy as compared with coal firing. Incidentally, it may be mentioned that the reduction in the fire-room force will go a long way to prevent the holding up of the ship on the point of sailing by suddenly announced strikes among the stokers.

Here in America, we have been fore-handed in the adoption of oil firing. The Shipping Board from its very first inception, grasped the great opportunity afforded by our construction of an entirely new fleet of ships and has made a wholesale introduction of the new system. The United States Navy also, is largely oil-firing and probably has a much larger percentage of oil-fired ships on its register than any other navy. This is particularly true of the capital ships and the destroyers, of which we built or commenced a great fleet during the war.

## Aeronautics

**Descent at 450 Miles per Hour.**—Lieut. Weiss of the French Army, was attempting to establish a height record recently but unexpectedly found his supply of oxygen virtually exhausted. The Paris correspondent of the *Morning Post* states that at the moment he was at 8,000 meters and his only chance of safety was to nose dive. For a certain number of seconds he achieved a speed of 450 miles per hour and actually traversed 4,300 yards of descent in thirty seconds. The machine was injured as a result of the strain and certain portions of the wings were torn off, while some supports also were broken before he was able to flatten out the machine for landing.

**Aerial Traffic Policemen.**—During the recent yacht races off Sandy Hook, N. J., the aerial policemen of New York City were given an opportunity of proving their worth. As it was, numerous aircraft hovered over the course of the racing yachts, and some of the more adventurous pilots essayed aerial stunts in order to attract attention. Soon the aerial policemen of the metropolis came on the scene in their high powered airplanes and immediately complete order and straight and sane flying obtained. While the work of the aerial policemen has been slow through lack of funds and support, it is safe to predict that this organization is steadily forging ahead in its work. The personnel includes some of the leading American fliers, and there now appears to be sufficient equipment and facilities to take care of the present aerial traffic.

**Mr. Fokker Speaks.**—Before the Royal Dutch Aviation Association at Rotterdam not so long ago, Mr. Fokker, the well-known designer of numerous German planes, expressed the pious hope that it would not be necessary for him to seek financial help abroad again, but that it would be found in his own country, Holland. He emphasized the need for developing machines which could leave the ground after a very short run, and instanced his new commercial machine as an example of what could be done. He expressed the idea that the improved reliability of airplanes would render seaplanes superfluous for overseas work except for trips between islands. He also pointed out the necessity for the extension of the application of wireless telephone and telegraph, and that the improvement of instruments for ascertaining heights, and so on, is necessary in order to make flights possible in fog at night, and under other hampering conditions.

**Zeppelins for France.**—*Aeronautics* says: France is to take possession of the two Zeppelins which fall to her share under the terms of the Treaty of Versailles. One is the L-72 and the other the LZ, of more recent construction. One will be allotted to the navy and will be stationed at Cuers-Pierrefeu, a naval aviation center in the Var. The other will be transferred to the Under-Secretariat, and will be housed at Maubeuge, in the hangar which the Germans enlarged during hostilities.

**Aviation and the Inventor.**—Writing of inventions we are inclined to believe that there is no field that offers more opportunity to the inventor than aviation. The science is really still in its infancy. Apart from actual constructional devices, there are so many obvious defects in the airplane that require remedies. Chief among them is the necessity for a braking device to give the machine only a few feet of run upon landing. Tail skids galore have been produced, but none can claim to be really effective. Brakes on the wheels have been tried, usually with the result of smashing the nose of the machine. An alterable chord on the wings has not proved altogether successful, and the alterable pitch of the propeller is not popular. The helicopter may come in time, but it is a long way from perfection yet.

## Astronomy

**Standard Time Adopted in Uruguay.**—A circular from the Meteorological Institute in Montevideo announced that, beginning April 30, 1920, the official time throughout the republic of Uruguay would be that of the 60th meridian west of Greenwich. The time signals sent out from Montevideo will in future conform to this time, instead of to that of 56 deg. 12 min. 45 sec. (the longitude of Montevideo).

**Salaries at the Naval Observatory.**—The U. S. Naval Observatory, in common with the other scientific establishments of the Government, is suffering from the monumental indifference of Congress with regard to the effects of inadequate salaries on the efficiency of the public service. According to the last annual report of the observatory, the amount of research work carried on during the last fiscal year was much less than usual. "This is so," says the report, "because of the necessity of employing the higher-grade assistants on certain routine work that could have been done by the three junior assistants had not these positions been vacant. It has been found impossible to fill these positions because of the low salaries."

**Variation of T Pyxidis.**—A bulletin from Harvard College Observatory dated April 9, 1920, records the interesting history of the star T Pyxidis, R.A. 9h. Om. 32s., Dec. —31 deg. 58.7 min. It was discovered by Miss Leavitt on photographs made in 1902, and was at first thought to be a nova. Its magnitude was then 7.4. An examination of 400 photographs of the region in question showed that it was also bright in 1890, while during the intervening years it was of about the 14th magnitude. A period of 12 years was thus indicated, but the maximum expected in 1914 did not occur. Recent photographs show that it has again become bright, after an interval of 18 years, its magnitude now being about 7. From a photograph made April 8, 1920, the star appears to have the early form of nova spectrum.

## CONDITIONS FOR THE $5,000 PRIZE EINSTEIN ESSAY CONTEST

1. No essay shall be longer than 3,000 words.

2. All essays must be in English, and written as simply, lucidly and non-technically as possible.

3. Each essay must be typewritten, and identified with a pseudonym. The essay shall bear a title and the author's pseudonym *only*, and must be enclosed in a plain sealed envelope likewise bearing this pseudonym. In the same package with the essay must be sent a second plain sealed envelope, also labelled with the pseudonym, and containing a statement of the name and address of the contestant, the pseudonym used, and the title of the essay. It is necessary to follow these instructions implicitly, in order to guard against confusion in opening the envelopes and assigning the pseudonyms to their proprietors, especially in view of the possibility that two of the contestants may employ the same pseudonym. The envelopes should be sent in a single package to the Einstein Prize Essay Editor, SCIENTIFIC AMERICAN, 233 Broadway, New York.

4. All essays must be in the office of the SCIENTIFIC AMERICAN by November 1st, 1920.

5. The Editor of the SCIENTIFIC AMERICAN will retain the small sealed envelopes containing the competitors' names and addresses, which will not be opened until the competitive essays have been passed upon and the winning essay selected.

6. As soon as the judges have selected the winning essay, they will notify the Editor, who will open the envelope bearing the proper pseudonym and revealing the competitor's true name. The competitor will at once be notified that he has won, and his essay will be published in an early issue of the SCIENTIFIC AMERICAN.

7. There shall be but one prize, of FIVE THOUSAND DOLLARS, to go to the author of the best essay submitted.*

8. The SCIENTIFIC AMERICAN reserves the right to publish in its columns, or in those of the SCIENTIFIC AMERICAN MONTHLY, or in book form, any of the essays which may be deemed worthy of this. Aside from such rights, the essays shall remain the properties of their authors; but no manuscripts can be returned..

9. The number and personnel of the Committee of Judges will be announced in an early issue.

*[The donor desired that in case the Judges were not able to agree upon the winning essay the prize might be divided between the contestants offering the best two essays, but the Post Office Department has objected to such a condition being published, so the matter is held in abeyance until definitely decided. Announcement will be made later in regard to the matter.—THE EDITOR.]

## Engineering

**Connecting Japan's Islands.**—A project for connecting Nippon, the main island of the Japanese group, with the neighboring island of Kyushu by means of a tunnel starting at Shimonoseki was originated by a Japanese shipping magnate, according to the *Economic Review*, but has been taken over by the Government, which is averse to giving out many details. It is understood, however, that borings have been made in the sea bed near Shimonoseki in order to ascertain the geological formation, and that in order to reduce the angle of inclination, the descent of the tunnel will commence about a mile from the coast, and at first run under the narrow channel between the mainland and the little island of Hikoshima, on which an underground station will probably be built. From there it will run under the actual Strait of Shimonoseki as far as the Dairi district a few miles to the west of Moji, where it will join the Kyushu railway. It is estimated that the construction of the tunnel, which will be six miles in length, will cost $12,500,000, and will be completed in 1929.

**Europe's Largest Cold-Storage Plant** is nearing completion at the Alexandria Dock, Liverpool. The first section of the store opened in August last, has a capacity sufficient for the storage of 11,000 tons of foodstuffs. When completed the total cubic capacity will be over 3,000,000 feet and the accommodation will approximate 30,000 tons of eatables, including meat, fish, poultry, game, eggs, butter, and cheese. The equipment will be the most modern obtainable. In order to avoid exposure of meat in transport from the ship to the shore, the adjacent dock sheds have been fitted with a system of conveyers which enables the meat to be picked up at any point and conveyed under cover direct to the store, thus avoiding any break in the refrigeration.

**Germany's Railroad Electrification.**—Coal as a power producer will be replaced so far as possible by the use of peat and the electrification of railroads in the vicinity of the large German cities, according to *Commerce Reports*. Great hopes are being placed on the new Theissen 10,000-horse-power vertical gas turbine, two of which have been ordered for use on the German railways. It is hoped that they will be able to replace the coal-burning locomotives. In regard to the electrification of the German railways near large cities it is planned to install large central power stations, which will be equipped with peat-burning furnaces. The peat bogs in the vicinity of Osnabruck will furnish this fuel. Machinery for the working of this peat has been installed, and it is hoped that the first deliveries will take place by September 1st next. Experiments are being made by the German Government with machinery for pressing the peat, so that it may be transported economically.

**The Teredo** does not actually eat the wood, but cuts into it as a place of abode while deriving its sustenance from the sea water, according to a recent account in *Railway Maintenance Engineer*, dealing with the ravages of the teredo and other insects of wood-boring habits in timber structure immersed in sea water. Impregnation with creosote has given a considerable degree of protection in many cases, but it has to be very thorough to be effective. Examination of creosoted structures that have been attacked has usually revealed incompleteness of the impregnation. Various forms of protection by external coverings have also been tried, including metal sheathings, coverings of burlap or sacking and protective pipes of cast iron, concrete or terra cotta. Practically all except the actual pipes proved of little value because their usefulness was quickly destroyed by breaks in the covering.

# Our Future Oil Supply

## A Hopeful View of the Possibilities of the Mexican Fields

By A. Hooton Blackiston

THE age of petroleum is here. From an humble beginning in 1859 it has now reached a point where it is consumed in ever increasing quantities until the problem of its production has become one of the most absorbing of international questions—to that country which controls the output belongs the power of the world.

Therefore, Great Britain, the smallest producer though realizing its importance, is struggling with every nerve set to acquire through purchase or otherwise the control of the known or prospective oil bearing areas of the world in Persia, Burma, China, the Balkans, Peru, Venezuela, Mexico and even in our own country. Meanwhile America, the home of the industry and the world's largest producer and consumer, sits idly by and watches its laurels slowly fade away.

Oil production means control of the sea and of the air and consequently of the land. It is time our Government wakened from its lethargy and encouraged production at home and abroad if we are not to be left behind in the race. Though we have produced over 60 per cent of the world's supply to date, we are now consuming more than we produce and the demand is increasing by leaps and bounds.

Petroleum is the genie that answers the lamp of Aladdin in a far more effective way than did the genie of the fable. It courses over vast stretches of country in its own pipes to do our bidding, it draws our trains, it cultivates our crops, it harvests them and hauls them to market, it drives and lubricates the wheels of industry, it heats our very buildings, it propels our navy and merchant marine, and in the submarine and the airplane it broks no rival. It does its work smoothly, effectively and economically.

And petroleum we must have, for we have built millions of machines that use nothing else and thousands of miles of road good only for them; we have adapted our vessels and locomotives to its use and are every day becoming more dependent upon it. Not a wheel turns but pays tribute to petroleum. Its sudden cessation would rock our present day civilization to its base.

The products refined from it are legion. There are over three hundred separate products made from petroleum. High explosives are distilled from it, medicines, dyes, and even artificial flavorings—and yet we have but begun to understand this modern wonder-worker.

It has cheerfully lifted the burden of labor from the back of mankind and his steadfast friend, the horse, and saved the drudgery of countless millions. In war it is our defense, in peace our aid, and in sickness our solace and our comfort.

However our reserve storage of crude oil has fallen off in the last eighteen months fifty million barrels and is decreasing at the rate of 10,000,000 barrels a month. In the face of these facts it is time we realized its national importance and looked ahead for our future supply.

*IN the midst of the prevalent gloom over the petroleum situation, it is refreshing to hear a note of optimism. We are usually told that the American supply is diminishing and will continue to diminish permanently; and that no substitute source of supply is in sight. Mr. Blackiston speaks from long familiarity with the Mexican field, and argues that this is not the case—that the republic south of us may be looked to for ultimate stability and a very large quantity of oil products.*

*But with his hopeful outlook he couples the suggestion that unless we bestir ourselves, we shall find the world's liquid fuel as completely in other hands as in the past it has been in ours. It is no remote inference, granting the validity of his arguments, that we may yet see the day when Britain will wallow in petroleum as we do now, while we parcel out the precious gasoline by the quart and even the pint, as Britain does today.*

—THE EDITOR.

The world's total output was 514,724,354 barrels in 1918. The United States produces approximately 69 per cent of the oil of the world and when combined with Mexico, about 81 per cent. In 1919, while we produced in round numbers 376,000,000 barrels our consumption was about 418,000,000 barrels; the difference of about 42,000,000 barrels was imported from Mexico, our nearest available foreign supply and the country which contains the premier wells of the world. Therefore, the Mexican fields are of particular interest to us when debating from whence our future supply is to come.

The petroleum industry in Mexico is only sixteen years old. It may be said to have been begun by Americans in 1904 in the Tampico district, though oil seepages were noted by the early Spandiards, and an attempt to drill was made in 1868, with no important discovery.

And yet, in spite of the newness of the industry and the numerous setbacks it has experienced through political conditions, the possible production of the country is estimated at nearly 2,000,000 barrels a day, though less than 9 per cent of this amount is exported at the present time, and but a fraction of Mexico's oil territory has even been prospected. In the brief sixteen years of its development it has climbed to the place of second producer of the world, and its wells are without a peer—indeed so far ahead of the others as hardly to admit of comparison.

It is a long cry from Drake's pioneer well near Titusville, Pennsylvania, in 1859, with its feeble stream of forty barrels a day, to the monarch of the world's wells, the famous Cerro Azul No. 4 of Mexico, which tossed its black column six hundred feet high into the air, and in unbridled freedom hurled over one million barrels of oil toward the skies before it was finally placed under control. It gushed at the rate of nearly three barrels a second, which would be 180 barrels a minute, 10,800 barrels an hour, or nearly 259,200 barrels a day, and at present is filling its eight-inch pipe lines running direct to the tankers at Tampico which are waiting with eager maws its flood of liquid gold. It is now producing at the rate of about 125,000

(*Continued on page 112*)

1. The standard bearer of our future oil supply—the test well, which today, with the aid of the scientist and the latest mechanical devices, indefatigably searches out the pools of hidden oils and opens new fields. 2. The driller has to be constantly on the job. 3. Incidents like this one in our own oil fields do not help matters.

## Scrapping Good Machinery for Better Service

By H. A. Mount

OUR great public service corporations spend many millions of dollars every year in replacing machinery and equipment, the mechanical usefulness of which is almost unimpaired by use. It is replaced because it has been antiquated by some new invention or development that gives better service.

To the uninitiated it would seem that the public might be spared a very great expense if this constant replacement of good equipment were stopped, or at least carried on less vigorously. But even a superficial examination of the facts discloses that it pays. Not only from the standpoint of the public is the process an economical one, but it pays dividends to the companies. And of course, that is the real reason for it. It pays so largely that the largest companies maintain great research organizations whose business it is to make antiquated the company's machinery and equipment—to find new ways of doing things.

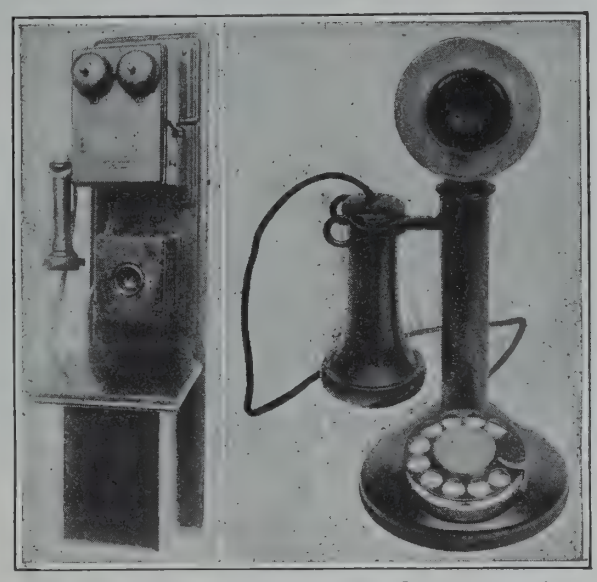
One of the striking examples of these statements is the electric light and power companies all over the country. There is hardly a central station in the United States which has not almost completely changed its equipment within the last ten years because of the rapid strides in electrical engineering. And yet the original equipment, if it had not been junked, would in most instances have been giving just as good service today as it did when installed.

The largest single powerhouse in the world, in point of electrical output, is one of the great stations which supply power for the operation of New York's subway system. Eight years ago this station was equipped with great reciprocating engines of 100,000 horsepower each, that were the finest engines of their kind in existence. It was estimated that they were good for a century of service. And yet today only one of these great engines still stands and it is used only in emergencies. The others have been replaced by a battery of comparatively small steam turbines that take up much less space and have a far greater power output.

The saving in fuel alone justifies the junking of all this costly machinery. The saving in space allowed for great expansion in power capacity without additional buildings. In this case junking good machinery has paid big dividends.

An even more striking example is our telephone system. Constant replacement is going on here on a stupendous scale. The most recent development in telephones is the automatic switchboard which does away with the much-abused but faithful servant "central." Connections are made automatically. The introduction necessitates replacement of almost the entire telephone equipment, but already the process has been begun and eventually it will extend to every city and town in the country. The saving in labor alone justifies the cost, aside from better service to the public. There will be no reduction in the number of employes, however, because of expansion of the system.

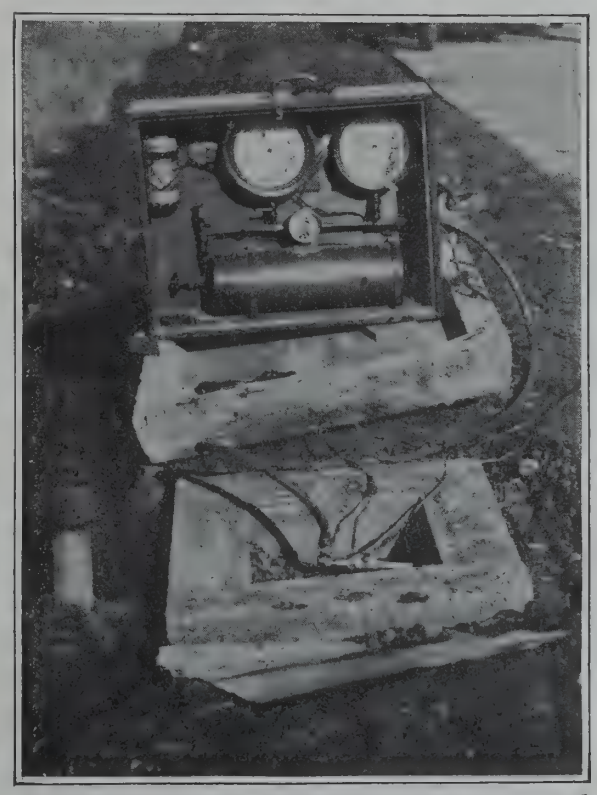
A few years ago the great mass of telephone wires in the cities made it necessary to use cables for transmission. At first only a few wires could be placed in a single cable and even then what seemed almost insurmountable difficulties presented themselves. The great cost of the cables and the expense of laying them, especially underground cables, made it necessary to put as many wires as possible in a single cable.



**The Blake transmitter of 1886, and the automatic instrument in use today**

An intensive engineering study of this problem has been going on and the difficulties have disappeared one by one as more and more of the overhead wires strung on telephone poles were replaced in cables underground. Finally, it became possible to place as many as 2,400

(*Continued on page 112*)



**The measuring box that reveals the pressure of a road on the bed of soil beneath it**

## How a Road Rests in Its Bed

By S. R. Winters

THE character of the support given a road surface by the underlying soil and the manner of distribution of pressure when highway slabs are subjected to the impact of heavy traffic, is scientific information for the first time disclosed by an ingenious apparatus designed by the U. S. Bureau of Public Roads. The tests are being conducted on a concrete highway leading into Camp Humphreys, Virginia, where army motor trucks with enormous cargoes of freight constantly travel.

The experiments are being conducted by a measuring box which has immediate connections with a pressure device located between the surface of the highway and the underlying soil. The initial tests showed that the effects of a motor truck at rest are never sufficient actually to shatter the road surface, this knowledge being of valuable assistance to highway engineers in proceeding with experiments in revealing the influence of trucks in motion and the effects of the impact.

It has been discovered that even a concrete road, stable and massive as it appears to be, is never for a single instant perfectly at rest on the underlying soil. It continually vibrates, which movements change the pressure exerted between the road surface and the underlying soil—a condition characteristic of any highway when traffic is passing over it. Irrespective of the size of the object, when a weight is placed on any kind of material, the latter is bound to deflect. The degree of its motion is dependent, of course, on the magnitude of the load applied as well as the kind and shape of the material. A road slab when subjected to oppressive motor truck traffic bends considerably, especially when the slab is resting on soft soil. If the bend is excessive, a crack is formed in the road surface.

The problems of highway engineers are constantly shifting front and each successive stage of changes presents fresh difficulties. In 1899 there were only 3,700 passenger and commercial motor vehicles manufactured in the United States. Previously the horse-drawn vehicle, having iron tires, produced an abrasive effect on roads, the surface wearing out under the continual grinding action. With the advent of the comparatively light motor conveyance, the effect of the rubber tire is to scatter huge clouds of dust, the fine stone particles tending to bind the road together—soon leaving but a stretch of disintegrated stone.

The third stage of highway engineering—the introduction of heavy motor trucks—has brought fresh problems. The new type of conveyance rumbles and pounds over the road surface, in many instances shattering the highways because they are unable to withstand the impact of excessively heavy traffic. So it is now a problem of design—the ultimate object of the Camp Humphreys experiments being to give the engineer complete information for designing highways when the surface rests on any type of soil.

## Soap from Lignite Tar Oils

EXPERIMENTS, which have been said to have a satisfactory result, have been carried out in the laboratory of the Siemens works in Berlin, with a view to converting lignite tar oils into fatty acids by the action of ozone. Similar experiments carried out on a large scale by a process introduced by the city of Wiesbaden have led to equally satisfactory results.

# The Romance of Invention—XV

## Frederic E. Ives, Wizard of Color and Light, and Father of the Half-Tone

By C. H. Claudy

THE probabilities that the reader has ever heard of a "kromoskop" or a "parallax stereogram" are small. But no one who reads but has seen half-tones, either black and white, two-color, three-color or four-color and has thus had his quota of pleasure and profit from the inventions and discoveries of America's most eminent authority on color processes, the distinguished inventor to whose resourcefulness and ability the world owes its premier method of illustration, indeed, the method which revolutionized the printing industry.

Mr. Ives, who confesses to sixty-four years, of which he looks about fifty, has spent those fifty in photography, first as an amateur, next as what those who recall his work there still speak of as the most competent photographic laboratorian Cornell University ever had, and the rest of the time in his own workshops and laboratories, where he has worked out hundreds of inventions, practically all dealing with light, optics, lenses, color processes and optical instruments of precision and photography.

Mr. Ives' story is so diversified that it is difficult to know where to begin. At best, no story the length of this article could more than outline his achievements. He himself, probably justly, regards his invention and perfecting of the half-tone process as his greatest claim to fame; but it is none so sure that a world well used to half-tones may not longer remember him as the first to invent, patent and perfect a "real" system of color photography as applied to the motion picture.

For this is Mr. Ives' latest contribution to the worlds of science, art and commerce; and that he has succeeded is not claimed upon theory, but upon the actual production of actual films in colors, which colors are in the films themselves, and are not added thereto by means of colored screens, a method which produces a color "flicker" or "color fringes."

It would be difficult if not impossible to describe the process in detail in a short space or without illustrations, but its simple principles may be outlined. Briefly, then, the process includes the making of two negatives simultaneously in two side-by-side cameras, synchronously operated. These two negatives are made, one by direct light through a di-chromic screen, the other by reflected light from the same screen, and both, by the use of prisms, from the same optical viewpoint. This screen is the wonder in the process, as it *transmits* red and *reflects* green light. From the resulting two negatives two prints are made, the first of which is direct upon ordinary positive film, which is then dyed with red. The second negative is then superimposed upon the dried and *resensitized* film, making a second print which comes out blue. By a chemical differentiation the first color gives not only the reds but the yellows and thus this strictly two-color process gives to the eye a three-color effect. The limitations of the process are in the slowness of printing the blue, which holds one printer's output down to about three hundred feet of film a day, and the expense, which is double that of ordinary black-and-white film. But the result is true color photography for the "movies" and Mr. Ives expects to cheapen and quicken the process to an everyday commercial standard. It has the great advantage over other moving-picture color systems that it uses standard film, a standard projecting machine, works at standard *or slower* speed, has *no* color fringes or flicker, and on account of the dichromic reflector used in place of ordinary color screens, can "take" the negatives with one-half the light (or half the exposure) used by other systems of moving-picture color photography.

Mr. Ives has invented so many systems of color photography that one rather fancies him several times a millionaire.

"Nothing of the sort!" he said, in answer to a question. "I never made much money out of any of my inventions. I am not interested in the business end of them, but in the problem. I have taken out sixty-five United States patents and many of them are in use today; but, alas, many of them lay idle until they expired and someone else has reaped where I sowed. Luckily, my pleasures are not in making money, but in doing the things which have to be done—solving the problems.

Had Mr. Ives received a fraction of a cent royalty on each square inch of every half-tone ever etched he would be so wealthy today that Rockefeller would appear poverty-stricken. When this was pointed out to him he smiled—he has a singularly vivid smile—and answered gently: "It's something to know that one's work has been of so much use to the world—something to be the father of the half-tone."

The inventor of the half-tone and of the motion-picture in color

"What do you think of the future of color photography for the amateur?" was asked.

"There are several processes he can use, if he will," was the answer. "But he won't. They are all a little too complicated and dainty in operation. The professional uses them little because of the expense attached, which makes it impossible to do as the average sitter expects—make a half dozen negatives and give her a choice! But any system of color photography which depends upon pigments on paper, no matter how applied, is at least but a compromise. The only absolutely truthful color process is my old "kromoskop" process—and the 'man in the street' called that a fake!"

Whereupon Mr. Ives demonstrated it to me, and would there were more fakes as beautiful! The kromoskop process shows a stereoscopic picture without any structure (such as half-tone dots or stripes or other grain) in absolute fidelity to nature's colors, be they violent or subdued. But the picture is a *picture of light*, must be viewed through a special instrument, is small and, of course, cannot be framed or put in a book for the parlor wall or the living room table.

"I was exhibiting this in London shortly after I invented it," Mr. Ives recalled, "and had a number of criticisms. One was from a successful artist, who said my greens were all wrong because they were a dull brown. Another was from a successful art critic who declared my greens were too brilliant and metallic. I let them argue the matter out with each other, and, for all I know, they are arguing yet. Neither would believe what I knew to be a fact, that one was slightly color blind on greens and the other on reds! For it is an oddity of this process that it reproduces colors perfectly for the normal vision, but not for the color blind!"

"You have received some medals for your work, I believe?" I ventured.

"Yes, some. I'll show them to you if you want."

I did want. Mr. Ives went out of the room (this was in his pleasant apartment in Philadelphia) and returned in a few moments. "I couldn't find them all," he said, "but these will do."

I imagined they might. The man came in with a *tray* literally dripping cases of medals—medals gold and medals silver, medals bronze and medals something else, medals large and small and intermediate. There are *five* John Scott medals from the Franklin Institute of assorted dates and for assorted accomplishments. One is for the diffraction chromoscope, another for Rowland diffraction-grating replicas (now used all over the world and making available for laboratory use a tool of the laboratory in scarcely less perfect form than the original itself, at one-fifth the expense) another for projecting lanterns, a fourth for isochromatic photography and the fifth for the "parallax stereogram," which is an oddity of science in which an apparently single picture, looked at without any apparatus, appears in strong relief. A modification of this invention, also patented by Mr. Ives, is frequently seen in advertising novelty displays in which a picture changes as the viewpoint changes—everyone is familiar with the first smiling, then frowning youth who changes his expression, actually with your viewpoint, apparently as he does or does not use so-and-so's shaving cream!

Mr. Ives has the Royal Photographic Society's Progress Medal, the Medal of the London Society of Arts (which he had forgotten he had won until he opened the case!), the Medal of the Photographic Society of Vienna, the Franklin Institute Elliot Gresson Medal, the Rumford Medal of the American Society of Arts and Sciences, the Royal Photographic Society of Great Britain Science Medal, the J. Traill Taylor Memorial Lectureship Medal, the Franklin Institute Medal, the International Inventions Medal (London), a special gold medal from the Photographic Society of Philadelphia, the Medal of the Royal Scottish Society of Arts, an inscribed watch from the International Society of Photo Engravers, the Franklin Institute Longstreth medal, and several Exposition medals.

Speaking of expositions reminded Mr. Ives of an amusing experience he had while exhibiting in Buffalo. The kromoskop takes its pictures in ordinary black and white and exhibits them in colors by the use of reflecting and refracting color screens. An authority of the exhibition in question wished to throw the exhibit out on the ground that it was a fraud and that any photograph viewed through color screens would appear as a colored photograph! This was matched by the comments of some near-scientists, when he exhibited what he calls "freak diffraction gratings" which behave as no ordinary grating could or should. The way they were made and the peculiarities of their performance were explained to the amusement of some students of optics, who apparently thought Mr. Ives a harmless but deluded crank who had stained some "regular" gratings. However, Pro-

(*Continued on page 112*)

*AMONG all the inventors whose work lies in some chosen and restricted field, none has elected a field in which the possibilities have turned out to be greater than in the field of photography. Photographic work, when Frederic Ives first took it up, was circumscribed enough. Largely through his inventions, this state of affairs has undergone a radical change, and today there are few arts of wider or more various application than the art of photography. It is a far cry indeed from the mysterious half-tone, with its little patterns of dots that make pictures, to the achievement of color photography and color motion pictures and color stereograms and the binocular microscope and the stereoscopic photomicrograph. Yet all these extensions of the photographer's province are the work of this one man, whose story Mr. Claudy here tells us.*—THE EDITOR.

## A Word for the Steam Automobile

To the Editor of the SCIENTIFIC AMERICAN:

The SCIENTIFIC AMERICAN has published from time to time descriptions of new types of steam automobiles and has likewise devoted considerable space in its correspondence columns to a discussion of this type of machine. Although the relative merits of the steam-driven and gasoline automobile have been a fruitful source of argument for twenty years, it seems to me that there are still a good many points that are not yet settled and which will bear further investigation and discussion.

I was much impressed by a letter of Mr. W. J. Parish, published in your issue of November 8, 1919, in which he gave his opinions very frankly concerning the steam car situation as it exists today though I think he magnified unduly the disadvantages of the steam car. As I have been familiar with steam automobiles for a number of years and own one at the present time, I should also like to express my views on the subject, perhaps along rather different lines from previous letters which I have read. I think that the present comparatively small use of steam automobiles can be explained by the fact that the motoring public of the present day is almost wholly ignorant concerning them. If one will go back to the early volumes of automobile journals, say along 1900 to 1902, one will find that at that time the steam machine existed on an equal footing with the gasoline car. In fact, it was probably more distinctly the American type of automobile than any other motor car then being manufactured. The steam machines built in those days were a remarkably highly developed type of automobile considering the time at which they were built. They were, however, for this very reason, considerably more complicated than contemporaneous gasoline machines with the possible exception of some of the imported French cars. Those were the days of very rapid development of the gasoline automobile and improvements were introduced almost daily. As the gasoline machines then built were very simple while the steam machines were even more complicated than the ones produced today, there was a decided swing away from the steam machine which seemed to be forgotten by a large part of the motoring public. Meanwhile the gasoline car improved in performance but only at the expense of additional complication, till in this respect it far exceeded the steamer.

A good many advocates of the steam automobile say, and I think not without truth, that if the two cars could start on an equal footing today the steam machine would soon be used in as large numbers as the gasoline.

The steam automobile at present is bought and used by people who thoroughly understand it and appreciate its many good qualities. From those I know who own this type of automobile I would say that scarcely one of them has bought a steam car with the same object in view as the average man who buys a gasoline machine. Steam-car owners are nearly always well acquainted with such machinery and are quite expert in doing their own repair work. These men can get the most out of the steam car; they know how to handle it intelligently and in case of any trouble are not dependent upon a service station. This is almost necessary in some places as today comparatively few repair men are familiar with steam automobiles. The owner of a gasoline car, on the other hand, buys one with the idea merely of running it and in the case of any breakdown taking it to the nearest repair station. I should say that fully three-fourths of the owners of gasoline cars do not thoroughly understand the mechanism and are not competent to do much repair work upon it. However, as they can always find any number of shops and garages within easy reach, they can get repair work done for them if they will pay the price.

I think that it is a mistake to try to compare the two types of cars as they are so utterly different. It is useless to suppose that a steam car, even with a flash boiler, can be built which can be started as easily as the modern gasoline car with its electric self-starter. (I refer, of course, to those times when the gasoline engine is in proper running order and will start after one or two revolutions.) Quick starting after a long period of disuse is the legitimate and great advantage of the internal combustion engine. Any boiler having a reserve capacity requires some little time to generate a head of steam from cold water. This is the disadvantage of the steam car, but I do not think it is as serious as the advocates of the gasoline machine would have us believe. After all, the times when we need a car on one or two minutes' notice are comparatively rare. The average man can nearly always tell a few minutes ahead when he will need his automobile and the length of time is generally sufficient to get up steam. If he needs a car that can start at any time on a few seconds' notice, he ought, of course, to buy a gasoline one. On the other hand, it is absolutely useless for the builders of gasoline cars to attempt to duplicate the steam car's performance as regards flexibility of control and ease in acceleration. These qualities are inherent in the steam plant and the various expedients such as gear shifts and multiple cylinders introduced on gasoline cars, are really only excuses for a type of motor which is fundamentally poorly adapted to variable speed work.

I do not attempt to argue that the gear shift, and 4, 6, 8 or even 12 cylinders have not been fairly successful. They have made the present day gasoline automobile possible, but, nevertheless, they are excuses all the same, and from the scientific point of view the gear shift is the weakest element of the whole car.

Good as the performance of the modern gasoline automobile is, considering the handicap due to the type of engine, the machine as a whole is, nevertheless, a collection of very complicated mechanisms and its reliability is really to be wondered at when one considers the amount of auxiliary equipment upon which the correct functioning of the whole machine depends. The steam car, on the other hand, is much simpler. It is true that there are valves and pipes and the burner to be looked after. All of them may give trouble, and yet it is almost impossible to "stall" a machine of this type if one or more of the parts of the power plant are out of order. Its performance on the road is so excellent that to my mind it is a strong argument for the use of such cars even when one considers their disadvantages, and these are not really serious drawbacks to any one who understands them. Before any large number of people can be induced to purchase this class of machine, they will have to become more familiar with it and with the theory of steam operation. While, as I have already stated, I think that three-fourths of the owners of gas cars do not really understand them, they think that they do, and they know that they know nothing about steam cars. The failure to educate the public along these lines is perhaps due in a large measure to the attitude of the steam car manufacturers themselves who have been content to sell their product to the few who really appreciated them without attempting to induce others to buy. Likewise, many owners of steam cars have apparently got a lot of satisfaction by giving the impression that such machines require vastly more intelligence to operate than the gasoline type which, I may be pardoned to state, is not at all the case. What is needed is familiarity with a different kind of machinery, functioning in a different way, and yet basically far simpler than the gasoline car.

There is a field, to my mind, for the steamer which cannot be filled so well by any other type of car. Likewise, there is the legitimate field for the gasoline vehicle. No argument is required today to prove that the gasoline and electric types of automobiles are both useful for certain particular purposes. Why can we not have the same attitude toward the steam machine? It is capable of doing wonderful work and for certain uses where its disadvantage, the inability at quick starting after a long period of disuse, is not a serious factor, it is the logical type to select, on account of its many other superior qualities.

Think of the great advantage of being able to burn completely and easily a cheap and heavy oil instead of gasoline for fuel! I have used both gasoline and kerosene burners and have had better success with the latter and have got greater mileage from my car. Burners can without doubt be designed to utilize even heavier fuels, and I think the time will come when engineers will be forced to recognize the fact that the solution of the automobile fuel problem is to be found in the steam car. Why go to the Diesel engine, which is even less adapted to vehicular work than the familiar gasoline motor, when the reliable and simple steam plant can be used?

I think a more friendly discussion of the subject is in order and might lead to much real good for the automobile-using public.

HUGH G. BOUTELL.

Washington, D. C.

## Visible Sound Waves

To the Editor of the SCIENTIFIC AMERICAN:

In connection with a letter of mine which was published in the SCIENTIFIC AMERICAN on March 6, 1920, under the above heading, my attention has been called to the fact that there may be some misunderstanding of certain statements made therein.

I referred to recent studies by Professor Sabine in connection with photography of sound waves and stated that his perfected apparatus was the result of several years of patient and skilful development. I did not wish to detract from the work of those others who have labored on the same subject and by whose studies Professor Sabine was able to profit. Professor Sabine called his method "A Modification of the Toepler-Boys-Foley method of photographing air disturbances."

Professor Arthur L. Foley of the University of Indiana, has done especially fine work along this line and my attention has been called to the fact that the SCIENTIFIC AMERICAN for February 15, 1913, published a number of excellent photographs taken by Professor Foley.

The development work done by Professor Sabine has resulted, in the opinion of the writer, in a method of photographing sound waves which is appreciably more satisfactory for the problems involved in architectural acoustics.

I hope you will give space to this letter in an early issue, as the writer does not want to have his letter convey the impression that Professor Sabine was solely responsible for the development of the modern methods of sound wave photography.

WM. H. CAPEN.

New York.

## Duluth to Liverpool

To the Editor of the SCIENTIFIC AMERICAN:

I have read with interest Mr. Skerret's article under the above title, which is an admirable statement of the project, and the reasons for it as we understand it.

I note your editorial in the same issue. I agree with you. New York should develop the Barge Canal to the fullest possible capacity. The West wants it and will use it for all it is worth.

The West wants all the service it can get from the railroads by any possible expansion of their facilities. It wants all the relief it can get from the present intolerable situation by the services of the Barge Canal, and it wants an entirely new outlet that it may have leave to grow according to the measure of its capacity.

What can the railroads do? Give them all the money they can spend. Give them carte-blanche—and in ten years they will have caught up with today's necessities. The West, meanwhile, is eager to expand its production. It looks as though the West must wait.

Perfect the Barge Canal. Work it to its capacity. The most it promises is a carriage of ten million tons a year eastbound. When the New York people proposed the Barge Canal as an adequate measure of relief, they remind me of the innocent gentleman of Boston who asked, "What is the matter with the Hoosac tunnel?"

Within four years from the time when Congress may act they can have relief through the lakes-to-ocean route. We can get relief in quicker time in the present emergency by this measure than by any possible improvement in the railroad situation. We can get adequate relief by this means where the Barge Canal will only allow a little trickle of traffic.

By all means let New York make the most of the Barge Canal, but do not make the fatal mistake of imagining that the country between the Alleghanies and the Rocky Mountains can find in that narrow channel an adequate outlet for the production, of which it is capable.

We welcome your views. I am sure that a further study of the intolerable conditions under which all these states suffer will bring you to a point of view identical with ours.

C. G. HARTLEY.

Duluth, Minn.

## Saving Shoes

To the Editor of the SCIENTIFIC AMERICAN:

I read in a recent number of vaseline applied to shoe soles to save wear. I believe a better remedy which I have used a long time is boiled linseed oil. Saturate the sole. Makes it hard as rock.

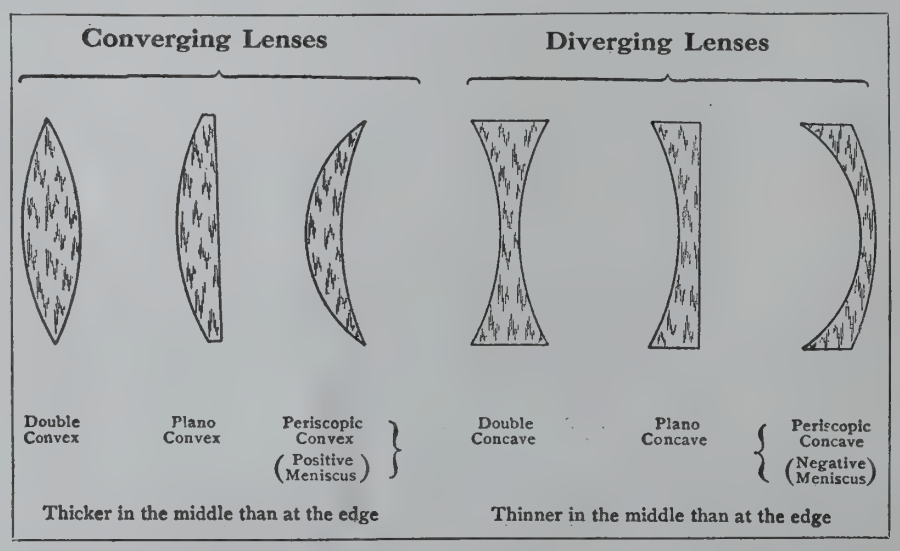
# Our Mechanical Eyes

## Glass for Optical Purposes, and How It Is Made

By J. F. Springer

WE are so familiar with glass objects and the material enters so into our every day life that it would be difficult mentally to reconstruct the world and visualize what our present civilization would be without it. And yet, the ancients either didn't have glass or had it only in a restricted way. Near the beginning of the Christian era, glass became known to the European world. The ruins of Pompeii, which was overwhelmed in 79 A. D., have yielded examples of small window panes. In these same ruins was found a plano-convex lens, presumably of glass. As lenses may be, and have been, made of rock crystal and other transparent substances, it would be unsafe to conclude that the ancient existence of a magnifying lens means a contemporary knowledge of glass. From the ruins of Nineveh, a city destroyed about 600 B. C., has been recovered what is probably the oldest known lens. It is plano-convex and is of rock crystal. It is not quite round, measures 1.6 x 1.4 inches on its axes and is 0.2 inch thick. Its refractive power is 10 diopters. This and other old lenses are, it seems, all of them of the convex class—thicker in the center than elsewhere. Pliny and Seneca, both of the first Christian century, tell us in effect that the Greeks and Romans were well aware that a glass globe filled with water produced a magnifying effect.

In our own days, glass objects are everywhere. Optical applications are very familiar. In fact, the number of spectacle lenses in actual, everyday use is enormous and their manufacture has become a very considerable department of industrial activity. Glass is used for giant lenses in our big refractive telescopes and in the construction of still larger reflecting mirrors used in certain great telescopes.



**Leading types of lenses in use in some of our cameras and other optical goods**

The reasons for the supremacy of glass in optical manufacture are, some of them, obvious or nearly so. Its wonderful transparency is one of these reasons. Its homogeneity is another. Then it may be molded or otherwise simply fashioned to approximate form and finished by grinding processes to an exactitude well-nigh inconceivable.

The small lenses used in spectacles and eye-glasses are made in enormous variety. Those required for big and little telescopes and for similar instruments greatly increase the ranges of variation, both in form and size. Nay, in optical matters, glass is not simply glass. There is, in fact, a big variety in the material itself.

In general, optical glass falls into two classes—lime glass and lead glass. The lime glass should, however, not be the usual thing used for ordinary bottles, window panes, etc., but a very clear variety. It is then called *crown glass.* Lead glass, often termed *flint glass,* is invaluable for special optical purposes. It may be made so as to possess a very brilliant luster, a high specific gravity, a high refractive index, and other good qualities. The two types of glass, lead and lime, may be conjoined for the purpose of securing optical results that are not readily possible with either alone.

One of the leading manufacturers of optical lenses says, in effect, that there is no glass in existence which possesses all the desired qualities in the highest degree. Clearness and responsiveness to molding operations are highly desirable. But optical requirements impose such further qualities as high resistance to atmospheric influences. Moist air, because of its content of carbon dioxide, acts upon glass surfaces by way of reducing brilliancy and transparency. Glass exposed to the air becomes more or less tarnished or coated, and the alkaline content at and near the surface is dissolved out, leaving silicic acid in the form of fine scales or flakes. These are naturally no longer glass.

The optical manufacturer can naturally have glass made to any specifications; but Nature herself hinders him. Lead and lime glass are so called because the one contains lead oxide and the other calcium oxide. Some silicate (as sand or quartz) and some such alkali as sodium, potassium or Glauber's salt are used in both. Now, the more silicic acid and calcium oxide that are present, the greater the resistance of the glass to atmospheric influences. But these substances, upon being increased in relative quantity, add to the infusibility. It is difficult to produce a hard and resistive glass that shall at the same time be pure. All increase in the alkaline content gives added fusibility, but it lessens the resistance to the air. Because of considerations of such character, the manufacturer takes a middle course.

Glass melts in the neighborhood of 2,700-2,900 degrees Fahrenheit. This is a considerable temperature, and the manufacturers are understood to resort, generally, to the Siemens regenerative system in the construction and operation of furnaces. A proper mixture of sand, calcium, and alkali is thrown into a red hot crucible. The mass immediately boils and ferments, carbon dioxide being evolved out from the seething liquid. From 18 to 30 hours is devoted to the melting. When the melt cools to a fairly low temperature, it is found to be viscid and suitable for manipulation.

Spectacle glass is ordinarily formed first in the shape of big cylindrical shells. These are cut parallel to the axis, reheated in a special oven, and then flattened upon a table with the aid of a long rod manipulated by the hand or with the assistance of some equivalent means. Next, the flat sheet goes into an annealing oven where it cools off by slow degrees. The thickness of the sheets is controlled by the amount of soft glass that comes away with the long iron tube when the latter is withdrawn from the molten mass in the crucible. Uniformity of thickness is another matter and requires skill and experience on the part of the glass blower.

Spectacle glass must naturally be clear. It must also be uniform and must possess such a degree of hardness as not to scratch. The resistance to air must be good. The fumes from concentrated muriatic acid when applied to glass afford a recognized test for excellence of quality, especially with respect to air-resistance. With lead glass, the crucible is covered, for the reason that otherwise the contact of the furnace gases with the lead results in a discoloration of the glass. In general, modern glass furnaces are heated exclusively by gas, this gas being made from coal, wood, or some other suitable material. If colors are desired, they are obtained by the addition of the proper metallic oxide to the molten mass. Cobalt oxide produces blue; chrome oxide, green; copper oxide, blue-green; but copper protoxide,

## Learning by Seeing

By George H. Dacy

MAKING practical application of the "Seeing is believing," slogan, the Bureau of Commercial Economics, Washington, D. C.—the greatest distributor of educational motion picture film in the world—is, at present, rotating its film resources of 35,000,000 feet of negative contributed by thirty different countries so that the pictures are exhibited to 2,000,000 people every twenty-six days. The ramifications of this unique organ of education are now so numerous and world-wide that it is possible to provide all portions of the globe from the frigid Arctic Circle to the plains of Senegambia and the steppes of Russia through 3,600 distributing cities with a change of "movie" film every week, supplied from over 100 film exchange centers operated by the organization.

The Bureau of Commercial Economics is an altruistic association which utilizes the facilities and instrumentalities of governments, manufacturers and educational institutions in the universal dissemination of useful information by the graphic method of motion pictures which are always displayed to the audiences free of charge. The free "movie" shows are held at universities, colleges, technical and agricultural schools, public libraries, state armories, community centers, state granges, settlement houses, missions, chambers of commerce, boards of trade, rotary clubs, fraternal institutions, welfare clubs, factories and wherever the people are interested and crowds can be assembled. Thirty-six specially equipped motor trucks provided in each instance with a powerful projector, an electric generator, a field phonograph and a collapsible screen are operated in carrying the motion pictures to the rural communities both in America and foreign countries.

Educational films—supplied by industrial, scientific and commercial enterprises as well as by the railroads—which portray every conceivable operation from controling a forest fire to making an automobile, from manufacturing pins to building locomotives, are distributed. Films are sent at regular intervals on dog sleds from Newfoundland to the Arctic Circle over a route which covers 2,100 miles. By means of portable projectors and small lighting generators, the Esquimos, lumber jacks, fishermen and prospectors of this northland country are regularly entertained—often in the ice-built huts of the natives or the crude shelters of the whites—with motion pictures which bring the doings of the outside world to these pioneering peoples.

Primitive carts drawn by oxen are used as the means of transportation in conveying the films and motion picture machines to the inland villages of the Dutch East Indies, while throughout the Orient the camel is occasionally harnessed as the beast of burden to carry the current events as depicted in pictures to the various tribes and creeds of the desert. The Hindoos of India enjoy the same "movies" which delight the natives of Peru, Chili and Bolivia; these get the applause of audiences of Inca and Hopi Indians as well as those of local assemblages in every state in the United States and every province in Canada. To Australia, South Africa, China, Japan, Russia, England, France, Italy, Denmark, Sweden, Norway and to every quarter of the earth where the motion pictures have

**An ingenious arrangement of gimbal rings and heavily-weighted pendulum serves to keep the motion-picture camera on an even keel**

penetrated, the "teaching-by-eye" films of the Bureau of Commercial Economics are now disseminated.

For a period of eighteen years, Dr. Francis Holley, formerly a builder of trans-continental railroads, was blind, due to paralysis of the optic nerve. During this time he traveled all over the world, visiting various eye specialists in hopes of regaining his vision. Ultimately he decided if ever his eyesight were restored that he would devote the balance of his life to making the world at large see things. Finally, by the use of high frequency electric current treatment, Dr. Holley's vision was restored, although as a consequence of the electrical treatments his lower limbs were paralyzed. He has made good his vow to carry visual education to the masses, he being responsible for the organization and success of the Bureau of Commercial Economics.

Nearly a score of years ago, Dr. Holley conceived the plan of teaching industrial workers concerning complicated operations in their respective factories by the use of films. Under his direction the first educational motion picture ever made was filmed in one

(*Continued on page 116*)

## Keeping the Camera on an Even Keel

By J. E. D. Meador

DESIGNED to overcome the effect of the camera's tilting while taking motion pictures on a ship's deck at sea, which makes the skyline appear to rise and fall, a device patterned after the marine gimbal has been constructed and employed by a motion picture company with excellent results.

The accompanying illustration clearly depicts the new idea. The camera resting on aluminum gimbals and, equipped with ball bearings, may be turned completely around without moving the tripod. The legs are made of 1⅜-inch steel tubing, the lower ends being fitted with adjustable pointed tips. The pendulum, an iron ball, with auxiliary weights, suspended by 1½-inch pipe, measures 34 inches in length. The ball and weights aggregate 150 pounds. To facilitate carrying, the ball has a cross pipe through it to serve as handles. With camera loaded the complete outfit weighs about 250 pounds. The tripod legs can be adjusted to give the camera an elevation of ten feet.

The gimbals were manufactured in New York from plans and embody several new ideas. A severe test that included exposing several hundred feet of film, while the camera was vigorously rocked, proved the device a success. The designer has taken steps to secure patents covering the most important improvements embodied.

## Telephoning in Cipher

EVERYONE probably has felt an uncomfortable fear, at times, that a private conversation over the wire was being listened to by an unbidden and unwelcome third party. Such listening in, in fact, is quite possible even on a private wire and many are the instances where information thus gained has figured in divorce courts, criminal cases, or the game of politics. In time of war, of course, such betrayal of guarded secrets may become a matter of life or death. Various methods have been employed for preventing such leakage. One that has been recently made known is the invention of a young French physicist, M. Poirson, attached to the laboratory of General Ferrié.

When vibratory currents are interrupted audition is greatly interfered with. In making experiments suggested by this fact, M. Poirson obtained surprising results. He found that if the current be interrupted with a frequency varying from 100 to 125 the voice is altered, becoming harsh and strident. When 125 to 170 interruptions are produced one hears a little better. With 210 to 270 interruptions the voice is once more greatly altered, but beginning with 290 interruptions communications are much better heard. These experiments suggested to the investigator the idea of replacing the interrupter by an inverter of the current. Rapid inversions modify the harmonic composition of telephonic currents and currents thus deformed become absolutely unintelligible over the telephone along the entire length of the line, producing upon the ear the impression of some weird unknown language. At the receiving end the telephonic currents thus interfered with are reëstablished in their normal order by inversions which are identical and synchronous with the former ones. The apparatus has been named the cryptophone.—By *M. Tevis.*

# The America's Cup Races

## Notes on the Contests for 1920

### By J. Bernard Walker

MANY people who witnessed the present series of races for the America's Cup have asked why the yachts did not sail "boat for boat," instead of one having to make the other the enormous allowance of over seven minutes—a handicap which would represent, at the maximum speed of these craft, nearly a mile and a half of distance.

The practice of granting time allowance to a smaller boat was long ago recognized as necessary for the encouragement of yacht racing. For size means speed, and, boat for boat, unless there is something radically wrong with the design, the larger craft will beat the smaller. So, gradually, a system of handicapping grew up, in which time penalties were imposed upon either waterline length, or beam, or draft, or sail area, or upon various combinations of these elements; and efforts were made to formulate a rule which would be so nicely adjusted as to give the smaller yachts an even chance of picking up a fair share of the cups in a season's racing.

It is because Herreshoff in designing "Resolute" aimed to produce a small, fast boat, and Nicholson in "Shamrock IV" aimed at a faster big boat, that the "Shamrock" has to carry the burden of a seven-minute handicap. The official measurements show that she has about 20 per cent more sail area—she pays about 5½ minutes for that. She is of a fuller form in the overhangs and is more than half an inch overdraft, and another minute and a half, more or less, of penalty is paid for these.

But, outside of the penalties imposed by the rule, there are others exacted by the inexorable laws of nature. For the official measurements show "Shamrock" to be some six tons heavier than "Resolute"; and it takes but a glance at her profile and midsection to see that her total wetted surface is far greater than that of the smaller boat—possibly as much as 15 per cent greater.

Now it takes a certain amount of power to carry that six tons of extra weight around a thirty-mile course, and it takes a large amount of power to overcome the skin friction of that 15 per cent excess of surface in contact with the water.

So it will be clear, we think, that in addition to the seven minutes handicap imposed by the rule, the "Shamrock" carries a self-imposed handicap, due to greater weight and wetted surface; elements that are inherent in the design.

Since the extra weight of "Shamrock" is comparatively negligible in its consumption of power, the question resolved itself into one of whether "Shamrock's" big sail area could beat "Resolute's" small wetted surface plus "Resolute's" big time allowance.

Thus far, the races that have been sailed indicate that in 30 miles of reaching "Shamrock" might save her time; that in 30 miles of running she would be beaten by two or three minutes; and that in 30 miles of windward work she would be beaten boat for boat by four minutes, or eleven minutes corrected time.

These estimates are based upon close personal observation of the two boats in the three races which have been sailed at the present writing; and it is scarcely necessary to add that the weak point of the challenger, in a comparison with "Resolute" is her windward work. Whether close-handed, reaching or running, she foots faster; but when sheets are tightened in for a turn to windward, "Shamrock" does not point so high, and though she foots faster, she does not pull out far enough to compensate for the leeway.

Whether the difference is due to a certain lack of balance in "Shamrock," or whether the ocean swell which has been prevalent so far, and has caused her flat forward overhang to pound heavily and throw her head off to leeward, is an open question. Probably she would show better windward work in a calm sea.

In the first race (15 miles to windward and return) the wind was fluky. "Resolute," however, demonstrated her superiority in windward work; but just before she reached the outer mark, her throat halyards parted, putting her out of the race. As these races are considered by the Cup Committee to be a test of good construction as well as of speed, the first race went to "Shamrock IV."

In the second race (triangular, 10 miles to the leg) the boats made a good fight of it in the light wind until near the first mark. Here "Shamrock" ran into a calm, while "Resolute," to windward, sailing in a favorable streak of wind, turned the mark and pulled out a lead of several miles before "Shamrock" found the same breeze. This race was called off because of the expiration of the time limit.

The third attempt was a race. "Shamrock" having the weather berth, carried a better wind, and this, coupled with excellent handling by Mr. Burton, put her around the first mark about 3½ minutes in the lead. In reaching to the second mark she gained another 5½ minutes, and she added one more minute in the ten-mile run, with spinnaker, to the finish, winning by 9 minutes 27 seconds actual and by 2 minutes and 26 seconds corrected time.

In this race "Shamrock" showed herself to be very fast in light weather with sheets started.

The situation now looked rosy for Sir Thomas Lipton. To win, "Resolute" must take three straight. If she lost a race, the cup, after 69 years' absence, would return to British waters.

The four races, finished or attempted, had been sailed in light airs—it remained to see how the boats would compare in a good, steady, wholesail breeze. The opportunity came on Wednesday, July 21, over a windward and leeward course of 30 miles. The predictions of those who had witnessed the earlier races were fulfilled. "Resolute" pointed higher and "Shamrock"

## The Mechanism of the Tides, and How Their Heights and Times Are Predicted

By Professor Henry Norris Russell, Ph. D.

MANY of our readers who are living for the summer, at least, beside salt water—as is the present writer—have doubtless been more or less careful observers of the tides and their phenomena. The main facts are so familiar to us that we hardly realize how remarkable they seemed to the Greeks and the Romans. Accustomed only to the almost tideless waters of the Mediterranean, those travelers of classic times who went so far afield as the shores of the Persian Gulf or the English Channel were amazed to see the waters retreat, sometimes for miles, across the sandy or muddy flats, and return, a few hours later, to fill all the space that they had left bare. They soon learned from the inhabitants of these coasts, and confirmed by their own observation, that these successive high tides came a little more than twelve hours apart, so that on each successive day the high water was about an hour later; that the low water came about half way between the high tides; that on and about the times of new and full moon the tides rose unusually high, and fell exceptionally low; and that when the moon was in her first and last quarters they neither rose so high nor fell so low as usual.

At about this point knowledge remained stationary for many centuries, through lack of any proper understanding of the cause which lay behind the strange change in the level of the sea. It was indeed clear that the moon must have something to do with the matter; but the nature of the connection necessarily remained unknown until Newton, by his discovery of the laws of gravitation and of mechanics, illuminated this very dark place.

Everyone knows now, of course, that the tides are caused by the attraction of the moon upon the waters of the sea; and most of us know too that the efficient cause is not the whole attraction of the moon, but the difference between the moon's attraction upon the whole solid mass of the earth and on the water of any given part of the sea. These two forces are not equal in amount or parallel in direction; and hence there is usually a small differential effect, which tends to tilt the otherwise level surface of standing water, now in one direction and now in another. In a small circular pond of still water, the level would rise at the side nearest the moon, and fall correspondingly on the other side, provided the moon was above the horizon—otherwise it would be highest at the side opposite the direction of the (invisible) moon. As the moon swung around the sky from east to west, the high tide on the edge of the pool would follow it. It would be highest when the moon was 45 degrees above or below the horizon, and would disappear when the moon was rising, setting, or directly overhead or underneath. It is not worth while, however, to look for such tides in a garden pool, for the greatest rise of the water in a pond 200 feet in diameter would be about one ten-thousandth part of an inch. By using long lines of pipe, buried in the ground and half full of water, Professor Michelson has succeeded in getting rid of the disturbances due to wind and weather, and measuring these changes in level with surprising accuracy.

### Little Tides and Big Ones

In a lake 200 miles across the tide would rise half an inch above the mean level and fall as low, giving a range of an inch. Tides of this sort have been detected in the Great Lakes by taking the average of readings of the water level on many days, at the theoretical time of high and low tide, and so eliminating the effects of wind and weather, which quite overwhelm the minute tides on any given day, but "average out" in the mean of years of observation. In the land-locked seas like the Mediterranean the tides are of much the same nature, and have a range of but a few inches, except in a few abnormal regions.

In the great oceans the effects are larger and far more complicated. The oceans cover such large parts of the earth's surface that the tidal forces acting on different parts of them at the same time are quite different, and the continuous changes due to the rotation of the earth add to the complications. Even so, the time and height of the tides might be predicted, if the ocean basins were of uniform depth and regular shape; but they are actually so irregular in form and depth, and so much obstructed and cut up by continents and islands, that a complete mathematical discussion of the motions of their waters is hopeless.

This much, however, we know. The moon comes back to (approximately) the same position, as seen from any given spot on the earth's surface, at regular intervals of 24 hours and 51 minutes, which we may call lunar days. At any given part of the ocean, therefore, the tidal forces due to the moon repeat themselves at this interval—running through their changes twice, once when the moon is above the horizon and once when she is below. The rise and fall of the tides must necessarily follow suit, and so the waters of the ocean will be set swinging, rising and falling twice in the interval of a lunar day. These oscillations are very similar in character to those that may be set up in a tub of water by raising one edge slightly at regular intervals, and, as in the simple case, the water rises in some places and falls correspondingly in others at the same time. If the period of the "impressed force" is very nearly that in which the water would naturally swing back and forth from one side to the other—whether of the tub, or of the ocean if left to itself—a small impulse, often repeated, may build up a very considerable oscillation of the water.

The tides therefore have a much greater range in some parts of the ocean than in others, and the time, as well as the height, of high water will vary from place to place; but the *interval* between successive high waters will be always exactly one-half of a lunar day.

The sun also gives rise to tidal forces, but owing to its great distance these are less than in the case of the moon and the corresponding solar tides are of smaller range. The interval between successive high waters for the solar tides is of course exactly twelve hours. They will therefore alternately get in step with the lunar tides, reinforcing these, and out of step, partially counteracting them. The former of these effects will evidently occur at the time of new moon, when the sun and the moon are close together in the heavens and are pulling on the sea in the same direction. It will also happen at full moon, when the solar tide has gained half a day on the lunar tide, and reinforces the other high water. At both these times, therefore, we get the spring tides, of large range; while midway between, at the quarters of the moon, we get the smaller neap tides.

### Further Complications

The principal characteristics of the tide are thus explained. To make predictions for any given port, we must find by observation at what hours of the lunar day (measured from the moon's meridian passage) the lunar tide is high and low, and how great is its range; and also, by comparing the spring and the neap tides, what is the range of the solar tide and at what hour of the day it is high. We may then proceed to predict the tides in future for this port, and should get fairly good results.

For example, the distance of the moon changes during the month, being five or six per cent less than the average when she is in perigee, and correspondingly greater in apogee. The tide-raising force varies inversely as the cube of the distance, and so goes to fully fifteen per cent on each side of the mean, being greatest at perigee. The height of the lunar tide changes correspondingly, and the time of high tide is also influenced, since the lunar days are longer than the average when she is in perigee and moving fastest in the sky, and are shorter near apogee. These effects can be represented by superposing upon a uniform lunar tide of the average range, another tidal oscillation also of uniform height but of period a little longer than the first, so that it gets into step with the other and reinforces it every time the moon comes to perigee, and is out of step with it and diminishes its influence half-way between, when the moon is in apogee.

Again, the two high tides of the same day are not always equally high, nor the low tides equally low. The reason for this is that when the sun, for example, is far north or south of the celestial equator, his altitude above the horizon at any given hour of the day will not be the same as his depression below the horizon at the corresponding hour of the night. The tidal force in the two cases, though nearly in the same direction, will be unequal in amount, and one high water will be higher than the other. Exactly similar effects occur in the case of the moon, and we have a "diurnal inequality" in the tides. This may be represented by combining with the principal solar tide, of period half a day, a subsidiary tide of period a whole day, which, for example, is always high at the time of one of the semi-diurnal high tides, increasing this, and low at the time of the other, decreasing that one. The lunar tides are treated in the same way. And to account fully for all the changes in the tidal forces, a good many more of these minor oscillations must be added—most of them, however, small.

If the height of the tide has been observed at a given port, at regular intervals—preferably every hour, by some automatic gage—for a year or so, it is possible to disentangle from the records exact information regarding the heights and phases of each one of the twenty or thirty minor tides (each one recurring with exact uniformity), whose combination represents the actual situation. By calculating the height of each of these tides, and adding them all up, the actual course of the tides can be predicted years in advance with surprising accuracy. This would be an appalling task if it should be attempted numerically; but it can be done mechanically by a very ingenious and complicated machine which only requires to be set suitably at the start in order to run off a curve on a long slip of paper which shows the whole course of the tides for a year. Such a machine is used by the Coast Survey in preparing the tide tables which they publish for the

*A Department Devoted to Progress in the Field of Applied Chemistry*

Conducted by H. E. HOWE, Chemical Engineer

## Water-Resisting Casein Glue

RESULTS from a series of experiments undertaken at the Forest Products Laboratory under the auspices of the Army and Navy have now been made public, and the casein glue, which has been developed there for airplane construction, should find rather wide application in industry. It has been determined that formaldehyde, sometimes used to coagulate casein, is not successful in rendering the product less soluble. All caseins, if reasonably pure, can be made into satisfactory glues, using the same formula but varying the amount of moisture. The most essential constituent used in casein to produce the water-resisting glue desired is lime, but the purity of the lime is not a determining factor. It is desirable, however, to use lime of known analysis and in employing new raw materials, tests of the water-resistant qualities of the glue produced should be conducted.

Casein is combined in its natural state with lime, from which it is freed by precipitation from milk, skimmed milk being the best source. The casein is not soluble in water, but is made into a paste with a solution of caustic alkali, and when the mixture dries, it is insoluble in water. Proof of the value of casein glue, as well as animal, vegetable and blood albumen glues, has been shown by subjecting samples to the action of gasoline, engine oil, and castor oil for twenty weeks, after which no separation of the plies was evident.

Complete information on this subject in the Technical Notes of the Forest Products Laboratory.

## Ang-Khak

ANG-KHAK is a red rice which is the source of a common vegetable color used in Chinese food products. The color is produced by certain strains of a mold, which spreads throughout specially treated rice kernels. The same fungus has been found in American corn, in silage, and is accountable for "freckled" salt fish. The finished Ang-khak is composed of clear-cut grains of a dark red color, which may be easily reduced to a fine, soft, red powder. The mold must be grown under controlled conditions, with particular attention to water content, which, if incorrect, will produce a grain which splits into fragments rather than breaking down to a powder. It is necessary to select proper strains of the mold, *monascus purpureus.*

## Tunnel Atmosphere

THE Bureau of Standards has been requested by the New York and New Jersey Vehicular Tunnel Commission to undertake an investigation of the atmospheric conditions which would be likely to exist in such a tunnel as is projected to connect Manhattan Island with New Jersey. In this study particular account must be taken of the exhaust gases from motor vehicles, in which, as is well known, carbon monoxide is to be found. Road tests have been begun with some eighty motor vehicles of different classes, and the results obtained from these tests differ somewhat from the block tests which have heretofore been conducted. In the near future a series of chamber tests on human subjects will be started and these chambers will be designed to represent cross sections of the tunnel as it is now designed. Inasmuch as there are similar tunnels under consideration for other cities, the work in question assumes increased importance.

## Empire Cotton Growing

IT will be enlightening to those interested in cotton to follow the efforts of the British Empire Cotton Growing Committee in increasing the supply of suitable grades of cotton fiber. The committee is of the opinion that within the British Empire both the quantity and quality of cotton required can be produced, and it is toward Egypt and the Sudan that they look for the most immediate large increase in the production of cotton. The African continent is looked upon as most promising, but before any considerable area can be brought into cultivation, large sums must be expended on irrigation, drainage, railways, water-ways, roads, and harbors. There is also need for greatly increased staffs of agricultural specialists and government control of seed supply, as well as of measures to combat insect pests. At this time, when the possibility of establishing an American Institute for Cotton Research is under consideration, it is well to note that the Empire Cotton Growing Committee places a central institute, in which all the sciences relating to cotton growing may be studied, as one of their first recommendations.

It may be that the time has come when much of the tropical and semi-tropical land may be brought under cultivation, for whereas this development could not go forward when the horse had to be depended upon as the only power for cultivation, the condition is changed by the advent of the modern tractor. The motor is also capable of bringing the crop to the avenues of travel, and in all of these agencies for the spread of civilization and increased production, chemistry has played an important part.

## Specifications for Basic Sulfate White Lead

CIRCULAR No. 85 of the Bureau of Standards has been issued, being a specification for basic sulfate white lead, prepared by the inter-departmental Committee on Paint Specification Standardization. With the various departments interested there were associated representatives of the Paint Manufacturers' Association of the United States, and prior to the publication of the specifications, a number of paint and varnish makers, including all of the large manufacturers of white lead, were asked to comment upon the poposed requirements.

The specification gives chemical and physical requirements of dry basic sulfate white lead and basic sulfate white lead ground to a paste in linseed oil. Methods of sampling and methods of testing both dry pigment and the paste are part of the specification.

## Energy Requirements

A WEEKLY news letter of the U. S. Department of Agriculture states that a family, consisting of a father, mother, and three children requires approximately 12,000 calories per day, and that the diet is best balanced by considering 120 units of 100 calories each. On this basis, fruits and vegetables should supply 24 units; milk, eggs and meat, 36; cereals and legumes, 30; sugar and starchy foods, 12; fats and fatty foods, 18.

## Desiccated Vegetables

DR. HAWK, of the Jefferson Medical College, points out that when desiccated vegetables are immersed in water for a few hours they assume a form very closely approaching that of the fresh vegetable, and that if this rehydrated material be removed from the water and left at room temperature for 24 to 36 hours it returns to approximately the same anhydrous state as before being freshened. This is an entirely different behavior from that observed in fresh vegetables, and the conclusion is reached that there must be a structural difference. The failure of the re-hydrated product to retain its water may be due to the change in the colloids of the vegetable cells, with an accompanying decrease in their power to hold water. The decrease in the inhibition power of the colloids might be due to the removal of mineral salts from the vegetable during soaking in water. These experiments have no reference to nutritive values.

## Physical and Chemical Properties of Copper

AT a recent meeting of the American Institute of Mining and Metallurgical Engineers there was a discussion of the relationship between the physical and chemical properties of copper, particularly with reference to the indication of chemical composition which certain physical characteristics indicate. Thus the appearance of the surface of the copper when cooled is termed its "pitch," which is the general contour of the surface of the shape, and this may vary from concave to convex. When the surface is concave, it is called a low pitch, and a convex surface is a high or tough pitch. A level surface is called a flat pitch. In the trade they go further and designate as the "set" the detailed appearance of the surface, that is, wave-like structure, and high pitch copper is usually described in terms of the set. If the set is very close and even, the copper content is about 99.95 per cent, and this same close set cannot be produced on a shape of low pitch.

Good electrolytic copper should have the following analysis, approximately: copper, 99.95; silver, 0.001; oxygen, 0.039; sulfur, 0.003; arsenic, 0.0015; antimony, 0.0020; nickel, 0.0015; iron, 0.0025; lead and bismuth, nil; selenium and tellurium, trace.

## Standard Materials

THE verification of analytical methods, the standardization of calorimetric work, and the determination of melting-points and similar scientific work depend very largely upon standard materials. For some time the Bureau of Standards has made a practice of supplying many thousands of samples annually, embracing iron, steels, ores, and organic compounds, upon which a great deal of work has been done, and with each a certificate was furnished for the guidance of those who depend upon them for their standards. This work has been made possible by appropriations, but the sale of samples has returned to the United States Treasury a larger sum than it has cost.

We have then a unique case, in that the work, besides being of fundamental importance to industries and educational institutions, is also self-supporting. It has been somewhat of a shock, therefore, to note that the House Committee on Appropriations has failed to provide any money for continuing this work, whereas a somewhat larger sum had been requested in order to extend this important activity. The failure to make suitable provision must be due to a lack of appreciation as to what these standard materials mean to industry, and it is hoped that active steps can be taken to insure the restoration of the item in question.

## Ceramics

DURING the recent meeting of the American Ceramic Society 131 papers were presented and many of these report results of scientific studies on the several problems peculiar to the various divisions of the Society. The field embraces enamels, glass, refractories, terra cotta, white ware, porcelain and kilns.

The point was made in some of the discussions that the day when scientific work was unappreciated in the industry is rapidly passing, and those with foresight have already set up their own scientific organizations. There are a number of problems, however, so fundamental that it seems worth while to attack them through some coöperative effort. The Glass Division passed a resolution to appoint a committee which will coöperate with the National Research Council, Division of Research Extension, for the purpose of canvassing the field. This committee will consider first, the problems which are suitable for such a study, choosing from the number a few to comprise the initial program; second, the facilities available for the work; third, the personnel having suitable training and experience; and fourth, a proper plan for financing the undertaking.

A Glass Research Association has already been formed in Great Britain and work there has actually been done. It is hoped that the movement which has started here will make rapid headway.

## Forging Iron-Nickel Alloys

IT has been established that pure iron-nickel alloys do not forge satisfactorily at ordinary forging temperatures, and at the Westinghouse Research Laboratory an investigation has been under way to determine what treatment would make such alloys more readily forgeable. It has been found that aluminum, chromium, magnesium, and silicon have scarcely any effect, but that in amounts of two per cent of the lesser constituents, manganese or titanium imparts the desired characteristics and makes the alloys forgeable.

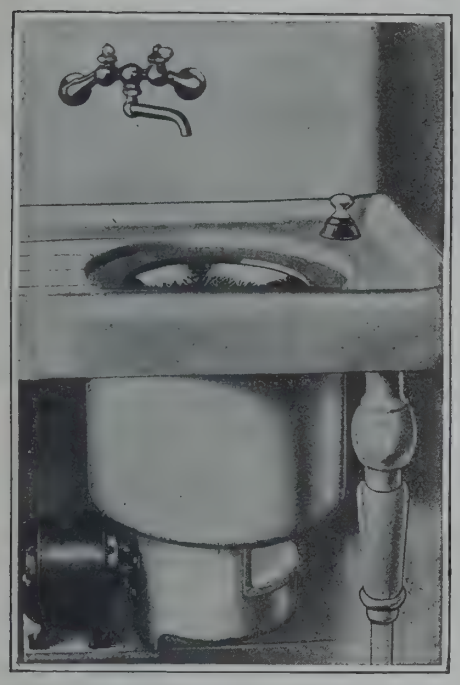
It is believed that these elements have the ability to strengthen the amorphous inter-crystalline material to the point where it possesses greater strength than the crystals.

## Coals for By-Product Coking

WHILE the chemist can make an accurate analysis of coal, it is not generally understood that such analyses cannot give results in terms of by-products from gas or coking operations. The chemist determines the elements which, under suitable conditions, combine to form ammonia, benzene, toluene, tar, etc., but he does not separate the coal into these substances. The amount of these by-products which will be produced depends upon many conditions, and indeed more upon the operation of the plant than upon the character of the coal. It is necessary to coke coal under commercial conditions and even a small-scale plant can do no more than indicate the possibilities so far as our present knowledge is concerned. In all this work the laboratory and semi-commercial-scale plant is a very valuable guide, but the limitations must be recognized.

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*



Dishes are washed in the sink by means of this washing device

### A Dishwashing Machine Right in the Sink

AN electric dishwashing machine which is built right in a porcelain enamel sink is a late product of a Chicago manufacturer. Power for washing dishes in this machine is derived from two perpendicular reels which throw the water with a tremendous force to the center of the bowl. The boiling water passes between every dish and flows off through the drain pipes. The dishes are placed in the machine in a permanent position and are not in motion during washing operations.

Any light socket or wall outlet will furnish the power to operate the ¼-hp. motor used with the combination machine.

### Locking the Shoes Outside the Hotel Bedroom

THE thief, so it seems, is always with us, no matter whether it be in the taking of automobiles, boats, jewelry, clothes or even shoes. Just now it is shoes in which we are immediately interested.

The practice in most Continental hotels is to place one's shoes outside the hotel bedroom door, in order that the bootblacks may clean and polish the shoes and return them by the next morning. But with the greatly increased price of shoes it seems that a new form of petty stealing has come into practice, namely, stealing shoes. So serious has this threat become that an English inventor has worked out an ingenious form of lock which appears in the accompanying illustration. It consists of a U-shaped member whose legs are pressed down into a pair of shoes to be locked in place. In this manner shoes may be locked outside the bedroom door with full assurance that they will not be stolen by the petty thieves engaging in shoe stealing.

Pushing down the U-shaped member locks the shoes in place

### Speeding Up the Camphor Harvest

DOWN in Florida and other Gulf States the camphor trees are cultivated in rows much the same as any other crop. Tillage is comparatively easy, but in harvesting the leaves and twigs the job becomes a tedious and expensive operation.

Heretofore the camphor-making material has been clipped from the tree by hand, which costly procedure doubtless is responsible for the advancing price of the product. But again the American inventor has come to the rescue in this all-important matter of reducing the high cost of production; this time it is the inventive skill of a specialist in the Bureau of Plant Industry, U. S. Department of Agriculture, that is responsible for a machine which strips the camphor trees of their leaves and small branches without injury to the limbs or impairment of the productive capacity of the trees. The machine, which is shown in the accompanying illustration, carries its own gasoline engine. As it is drawn between the rows of camphor trees, its cutting knife cuts off the leaves and small branches.

Hand work in harvesting camphor-making materials is done away with by this recently-introduced harvester

### War's Explosives and Italy's Agriculture

WITH a view to disposing of the surplus supply of explosives and at the same time benefiting agriculture, many experiments have been conducted by the Italian Ministry of War in connection with the breaking of ground. The results have been so satisfactory that it has now been determined to proceed to the practical use of explosives in agriculture on a large scale. In addition to preparing the land for cultivation, it is claimed that the use of certain explosives not only destroys parasites but also to a certain extent reduces the necessity for fertilization. It is proposed to establish in all districts of Italy demonstration fields where trials of the system which has been adopted will be carried out; such fields have already been created in Umbria, Puglie, Tuscany, and the liberated Provinces. At the same time, the Mininstry of War will turn over the large quantities of available explosives at favorable prices.

### Gluing Mandolin Backs by Machine

A NEW time, space and labor saving automatic drying and gluing machine has been invented by the foreman in one of the largest manufactories of musical string instruments in the United States, located at Jersey City, N. J. This new machine, as can be seen herewith illustrated, enables the operator to glue and dry hundreds of mandolin and guitar backs in a short time. Ordinarily a mandolin or guitar back is glued and put in a device which holds the two pieces together under pressure, and then placed on the floor to dry. Hundreds of these upon a floor, especially in a factory, take up lots of room and take up many an extra hour with operatives who are being paid for their time. With the invention of this new machine a general saving is made by the firm.

The machine is operated in the following manner: Place a glued back on one of the racks, which are found on the revolving wheel or machine. When the rack reaches you for the second time the back is both dried and glued thoroughly. Then you are in a position to put on another mandolin or guitar back for drying and gluing.

### A Turkish Bath for Milady's Hair

IT may be that one of the aftermaths of war is a most strenuous effort on the part of the fair sex to appear at its best. Those who are blessed with natural beauty seem to strive in every way to exploit their charms to the utmost, while those not so blessed strive a hundred-fold more energetically to acquire beauty in every possible manner.

However all that may be, the fact remains that inventors have been working on the problem of beauty with more than usual vigor. Numerous beautifying devices have been patented since the ending of hostilities, and more keep coming along week by week. All of which, to be sure, presages a genuine demand for such devices. The Turkish bath arrangement shown in the accompanying illustration is one of the latest devices along this line. It consists of a canvas hood, electric heater, and steam-producing arrangement. When the device is placed on the head and the current turned on, the hair of the patient is treated to a steam bath which, so we are told, is conducive to a wealth of beautiful hair.

This machine serves to glue hundreds of mandolins in a short time

### Peat Fiber and the Textile Industry

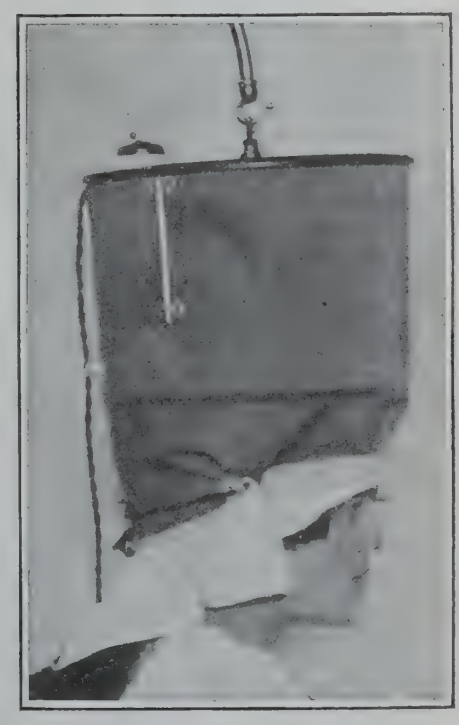
SWEDISH efforts to introduce peat fiber as a substitute article in the textile industry have come to naught for the moment. It is the consensus of opinion that the prices for extracting the fiber from peat moss must be economical before it will ever come into general use. Two factories, one in Denmark and the other at Partille, near Goteborg, Sweden, both established during the war for the purpose of utilizing peat fiber, have had to close their doors in recognition of this fact.

The experts appointed to make the investigation have completed their labors, and, among other things, found:

(1) Good textiles of peat fiber and "shoddy" can be manufactued and samples were demonstrated, but

(2) The Swedish peat mosses can produce only 100 kilos of fibers and moss per day, which is not sufficient for commercial purposes.

(3) The methods so far used in obtaining the fibers are too expensive.



This electrically-operated device treats the patient's hair to a Turkish bath

**Holds tight in tight places**

When rolling down hill like an avalanche you don't have to take everything with you as you go.

For Garco will hold your car in check whenever and wherever the occasion demands. Among those who know, Garco is noted for its strength and lasting qualities. And it has a grip like the handshake of Samson.

## Our Future Oil Supply

(*Continued from page 102*)

barrels of oil a day settled production, more than our famous fields of Ranger, Desdemona and Cushing combined, with their thousands of wells. Against them all stands the peerless Cerro Azul No. 4 alone, with its depth of but 1,752 feet, and proudly outmatches not wells or even single pools, but groups of fields instead, keeping up an output which they can only maintain by means of the constant addition of new wells. During the first week when it came in that one well alone produced about one-sixth as much oil as all the wells in the United States together.

Then comes the Juan Casiano, with its output to the present of over 8,000,000 barrels and which still is producing at the rate of 23,000 barrels a day through a damaged valve, and the Portrero del Llano, which produced 100,000,000 barrels before it was drowned out by salt water. It flowed 46,000 barrels a day for years—a greater output than the entire Healdton field of Oklahoma—the casing being defective, and great seepages coming up through the ground for a radius of half a mile. Truly, Nature has been kind to Mexico!

A flood of oil like that set forth in these figures is hard to comprehend, and still more bewildering when translated into dollars and cents.

These wells are by no means alone. There are others that stand out as giants among the wells of the world. Two were brought in a short time ago with an initial or flush production of between 60,000 barrels and 80,000 barrels a day, the latter having a production almost as great as America's largest field—the well-known Burkburnett pool of Texas; and dozens of others run as high as many of our smaller fields. Indeed, a report places a recent daily output of three hundred and five Mexican wells at 1,925,233 barrels, or 6,312 barrels per well! An average of 200 barrels a well for an entire field is regarded as exceptional on this side of the Rio Grande. Mexico's total supply comes from but little over 300 producing wells, which have only been run irregularly; and yet these with their partial output produce annually the equal of 37,500 wells here, or approximately one-sixth as much oil as the over 225,000 wells in this country.

The Mexican fields are divided into three districts or zones. The heavy crude oil is produced in the "Northern Field," lying west of Tampico, and comprises the Ebano, Panuco and Topila fields, of which Panuco is the most prolific and Ebano the scene of the first gusher in Mexico. The oil is from 8 to 15 (Beaumé) gravity.

The "Southern Field," or the light oil district, begins at Tepetante, about 72 miles south of Tampico, and extends 36 miles to the south of the Tuxpam River. The oil is about 22 (Beaumé) gravity. It is here that the famous oil bearing Tamasopa or honey-combed limestone is encountered, which is stated to have a thickness of one or more miles, and which accounts for the wonderful capacity of the wells. This field was opened in 1910 with the great Juan Casiano and Portrero del Llano wells previously described.

The third zone is still farther south on the Isthmus of Tehuantepec, and is known as the "Isthmus" or "Tehuantepec" field. While the production at present is not as great as that of the others, the oil is of much higher quality, about 37 Beaumé, and vast stretches of probable oil territory in Tabasco, Campeche, Yucatan, Chiapas and Quintana Roo have not even been prospected. It is in this field that the Pearsons of London have their well known Salat well, and also their refinery at Minatitlan.

These three districts form the producing fields of Mexico today—starting with the low grade oil in the north and increasing in quality toward the south. The west or Pacific coast has not yet been developed for oil but portions of it look most encouraging, especially parts of the Pacific littoral of lower California, which the Mexican official reports designate as a petroleum-bearing region. Oil outcroppings are found there in several places and the geological formations give most favorable promise. The large companies are reported to have acquired huge domains in this section and geologists claim that some of the greatest deposits will be uncovered there.

In the eighteen years in which the writer has known Mexico he has never encountered anything but exceptional courtesy from her people, or other than utmost consideration from the government despite the fact that he has been there in most trying times.

Verily, Mexico is a land of riches. Nature has given her every available climate, elevation and geographical and topographical formation—a soil that in places is a marvel of production, fisheries of great richness, mines that produce gold, copper, antimony, etc., and for years contributed one-half of the world's supply of silver—and below lie the vast reservoirs of petroleum, which today have hardly been tapped and the possibilities of which have not even been explored. These fields now bid fair to see a campaign of development that will again startle the world and that will add untold millions to its wealth.

## Scrapping Good Machinery for Better Service

(*Continued from page 103*)

wires in a single cable and cables laid as late as 1916 contained circuits having 320 pounds of copper per mile. Today cables containing only 80 pounds of copper per mile are being used with better results. At the same time cables which were useful only for very short distances have been improved so that now conversations are regularly carried on over a thousand miles of cable. New inventions make it possible to talk from New York to San Francisco by cable with no more difficulty than was experienced only a few years ago in talking from New York to Boston on overhead wires. The present advantage of cables over wires is so obvious that this replacement is taking place all over the country just as fast as the new equipment can be manufactured. It is estimated that the saving to one company from this single change, ten years hence will amount to $5,000,000 a year!

Of course these two improvements in telephone service—the automatic connection and the cable—are largely an apparatus with which the average subscriber does not come in contact and about which he does not bother. But within the memory of nearly all of us, the telephone instrument itself has been replaced several times. It wasn't so long ago that we were talking into great cumbersome battery phones that hung on the wall, and were calling "central" by cranking a little magneto. This has evolved into the convenient desk phone of today. Each replacement has meant the expenditure of millions of dollars and the saving of many other millions.

Today there is a great engineering laboratory in New York employing 3,125 men and women, which has as its sole purpose the improvement of telephones and telephone systems. During the past year this laboratory has actually prosecuted work on more than five hundred improvements in the telephone art. All of these promise advances in the interest of service or economy. Many have reached the point where success is assured. Others will require many years of development before any practical results can be seen. Some of them look so visionary and unpractical that it seems a waste of money and time to carry them further. Yet thousands of dollars are spent on such things annually in this laboratory. And it pays!

It must not be inferred that the laboratories which are responsible for great advances in public service are an inventor's paradise or that every new invention wins instant recognition from a wizardly set of directors. The men who direct these laboratories are serious-minded scientists and engineers, who arrive at their conclusions after most thorough study and experiment. There is nothing haphazard about it and when a great advance is ready for practical application it has been calculated beforehand just what the saving will be and it has already been demonstrated on a small scale. That is why it pays.

## The Romance of Invention—XV

(*Continued from page 104*)

fessor Michelson, one of the greatest living authorities on such matters, happened along in time to express his interest and declare their genuineness to the discomfiture of Mr. Ives's critics.

Mr. Ives has been responsible for so many oddities in light, color and picture that a catalog would be almost wearisome. But it would be criminal to neglect to mention the binocular microscope which can be used with high powers as well as low, and for stereoscopic photomicrography under high powers Mr. Ives has made stereograms of small diatoms which, when viewed in a stereoscope, have the appearance of richly carved cut glass dishes. Any microscopist who has first found, then resolved, and finally studied these diatoms, famous test objects for fine lenses, will appreciate that a device which will make steographic photographs of them through an oil immersion one-twelfth at 1,700 diameters is worth mentioning here!

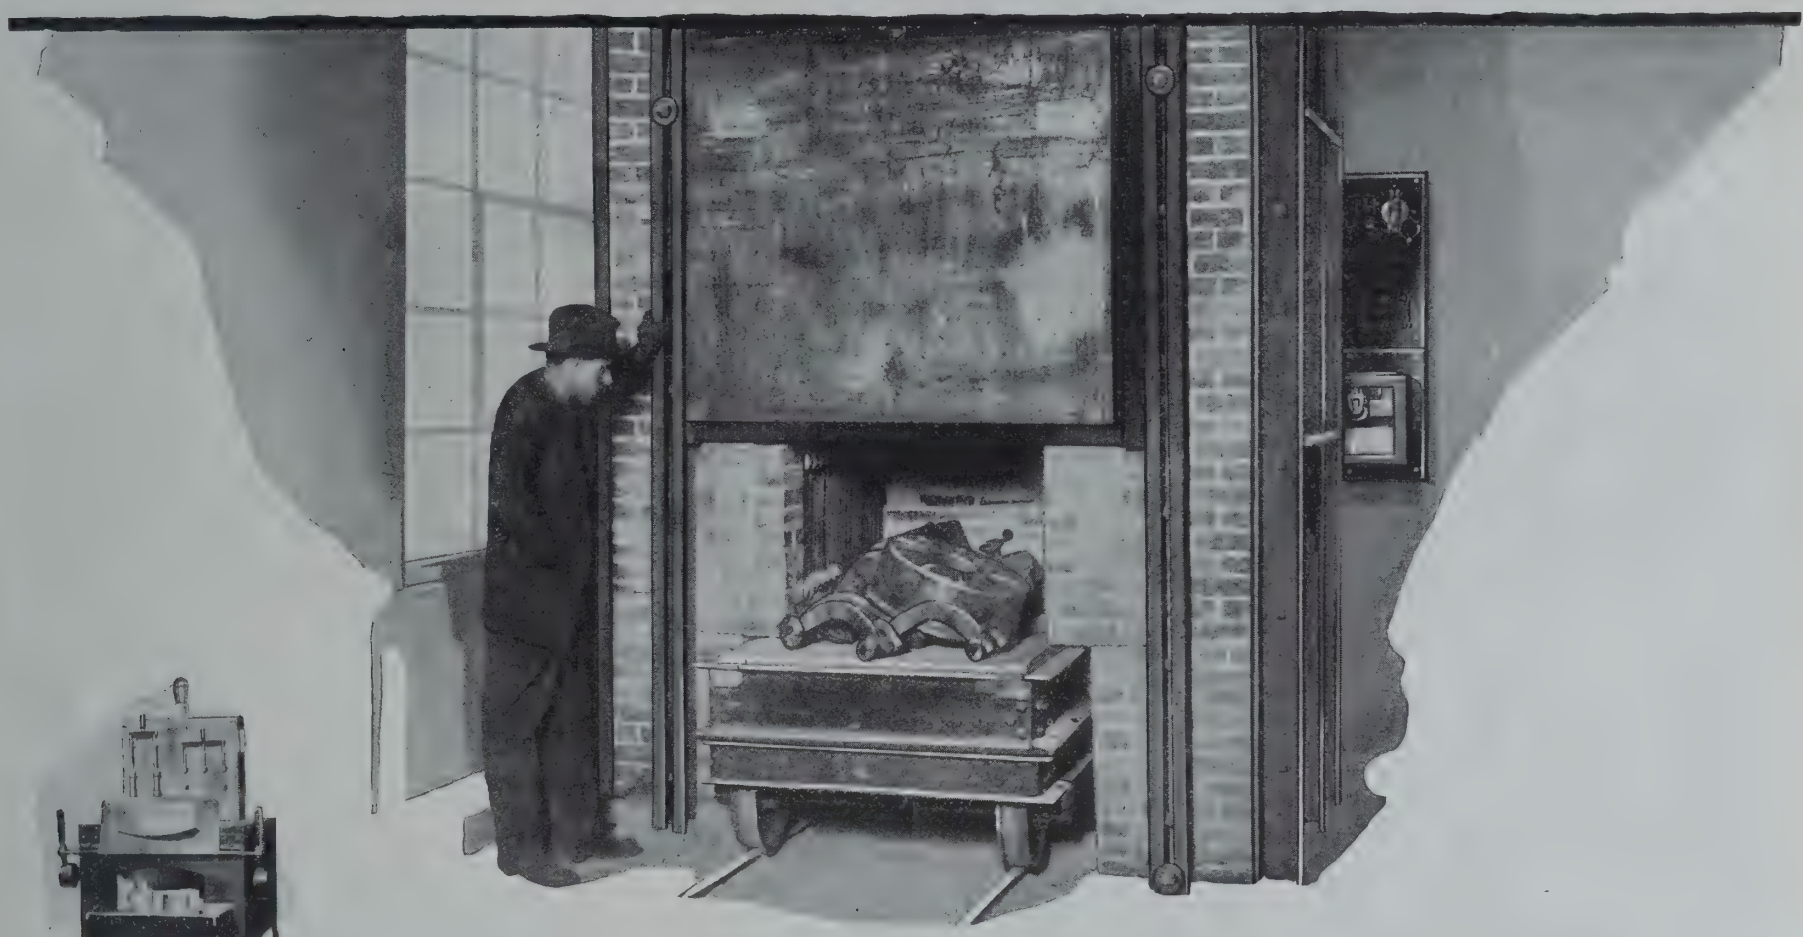
Mr. Ives was born in Litchfield, Connecticut, where his father first had a farm and then conducted a store. The young Ives started as a farmer boy and a store keeper. While in the store he took up amateur printing and at the age of 16 was a journeyman printer and amateur photographer by the old wet plate process of that day. He made his first camera out of a cigar box and spectacle lens and made good negatives with it. He then went to Ithaca and there, as a lad of nineteen, applied to Professor Anthony for the job of photographer in the University photographic laboratory. The learned professor would have none of him at first on account of youth and inexperience, but Ives persevered until he was allowed to try, probably as the easiest way of getting rid of him. He stayed four years because, as Professor Anthony said, before he came they had never been able to get such good work done.

During this time Mr. Ives endeavored to learn wood engraving, but without distinguished success. It was to substitute for the engraver's "V-shaped tool," a "V-shaped graver of light" that he went to work, the result being the familiar half-tone process. Worked out first as a photomechanical process and introduced commercially in February, 1881, in 1885 and 1886, the present-day half-tone screen system was developed from it and that process given the world which made the modern illustrated paper possible and revolutionized the printing industry. Incidentally, it may be mentioned that Mr. Ives has in his files a patent applied for in 1891 for the type of intaglio printing plate used in the present system of rotary photogravure, which illustrates in brown ink our familiar Sunday supplements.

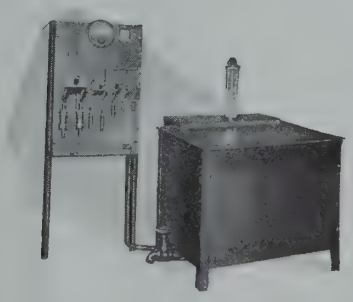
Following the half-tone process, the three-color process was Mr. Ives's work, and to his genius and knowledge of optics we owe that wonderful art by which colors as nearly natural as pigments can accomplish can be laid on paper by the printing press in thousands, even millions, of copies in a short time.

(*Continued on page 114*)

*Perhaps the surest proof that electric heat has graduated from the experimental class is the use of 1,000,000 kilowatts for industrial applications*



*Muffle type heat treating furnace*



*Electrically heated oil tempering bath*

*Core baking oven*

# A Furnace that can't get too hot

WHEREVER human life depends on pieces of steel for safety and strength, as in axles, wheels, gears and many other parts of machinery, the heat treating of those steel forgings or castings is all-important. Too much heat is just as bad as too little, and a few degrees either way is enough to make the steel unfit for its purpose.

Since accuracy of temperature is so vital in heat treating, the electric furnace far surpasses any other form of heat, because its control is absolute and its results are constant, day after day. If a certain temperature is required, the electric furnace will not only maintain that *exact* temperature for any given time, but will distribute the heat evenly in every part of the furnace, so that the product to be treated will receive the same amount of heat from all sides, top and bottom. This is all done automatically, with one man controlling several furnaces.

Improved working conditions, such as absence of noise and excessive heat, perfect cleanliness, and simplicity of operation tend to make happier workers and better work. Production is increased and costs decreased through more uniform results, minimum amount of re-working, and less distortion of forgings.

G-E electric heating equipments are made for furnaces of various sizes, for temperatures up to 1800° F., and are being used for heat treating, annealing, carburizing, and hardening metals, in many industries.

While equipping furnaces constitutes a large part of the General Electric Company's share in the development of electric heat, there are many G-E heating devices for other purposes. From the miniature cartridge unit which heats a soldering iron, to the monstrous oven which bakes enamel on automobile bodies, electric heat has established itself firmly, and has exceeded the fondest hopes of its most ardent exponent.

The facts and figures gathered from hundreds of G-E installations are available to anyone who has an industrial heating problem, simple or complex.

"A Splendid Service Station"

YOU have seen the average garage or service station. Wide floors; good light close to the windows but almost none elsewhere; constant recourse to drop lights and extension cords for repair work: the air often cloudy with smoke.

This service station is different! Although it measures 210 x 225 feet, every part is well lighted even when the floor is filled with motor trucks. Three modified Pond Trusses in the roof—one over each 70-foot bay—give a cross lighting effect that minimizes shadows far better than a sawtooth roof. And the long lines of top-hung Pond Continuous Sash give uniform outlet to heat and smoke with full weather protection and easy control.

In the walls are two lines of Lupton Pivoted Factory Sash. The upper ventilators, like the roof sash, are opened or closed en masse by Pond Operating Device, thus ensuring even distribution of fresh air regardless of what is done to the lower ventilators.

By correctly planning both the windows and the building as a whole, results may often be obtained far beyond those possible with conventional design. We gladly place our wide experience at the service of intending builders and their architects.

## The Romance of Invention—XV

(*Continued from page 112*)

Mr. Ives, while freely crediting to another the principles of panchromatic photography, was the first to realize a successful process in commercial practice. His inventions also include a color meter—a device for measuring color and tints which has the possibility of more than one million variations, and of hundreds of variations of any one shade. Any color can be matched to the eye and expressed in simple numerical terms.

It must not be supposed from anything said above that Mr. Ives regards as impossible the making of color photographs on paper by a process so simple that any one can use it. His own "hichrome" process has been exploited commercially and does produce results which are beautiful and sincere. That it might be simplified is by no means, in the inventor's view, impossible. But he will tell an inquirer that inasmuch as nature provided three primary colors, which, by combination, produce the sensation to our eyes of all other colors, a less-than-three-color process does not appear feasible if it is to be truthful, and that wherever there are *three* negatives and *three* prints, which in one way or another must be presented as *one* to the eye, there must also be difficulties of manipulation and coördination that are apt to make trouble for the tyro. But he has by no means given up work either upon this or any one of a dozen other processes which he has and is working out, and indeed, is even now fitting up a new laboratory for the special investigation of color reproduction problems.

Mr. Ives believes that there is a great future for motion pictures in color, the colors of which will be nearly if not quite natural and which will be as much without flicker or mechanical or financial difficulties as the present black-and-white moving-picture films are; and he has high hopes of the commercial value of this, his latest contribution to the science of picture making.

That some one will make money out of it seems assured, even as millions have been made out of Ives's inventions by others.

"But I haven't time to make money," says Mr. Ives. "There is too much else to do."

Incidentally, it should be chronicled that America's foremost authority on the subject, who has been honored at home and abroad for his researches, his inventions, his papers and his knowledge, is *not* a graduate of any college and holds *no* degrees, probably for the same reason he hasn't made himself a fortune—he has been too busy making and perfecting inventions to have time!

## Our Mechanical Eyes

(*Continued from page 106*)

red; gold, ruby; silver, yellow; iron, greenish; manganese, violet. If a smoked effect is desired, it may be obtained by combining several of the foregoing oxides.

The spectacle sheets are gone over and many discarded for lack of the desired excellence in some respect or other. The sheets which pass inspection are now cut into circles or ellipses by a special machine which operates a diamond cutter.

Optical flint glass, which contains a good deal of lead, may be prepared by using pure red lead to supply the lead, or else litharge (the semi-vitrified protoxide of lead). A normal flint glass will result from the use of 3 parts of sand, 2 of red lead, and 1 of potassium. The great difficulty in the manufacture of optical flint glass centers on the elimination of bubbles, strains and striae. The lead tends to sink because of its considerable specific gravity, so that the mass must continually be stirred. The melting of the metal may last a number of days, so that the stirring is by no means an evanescent job. It is undesirable to have the iron rod in contact with the glass. A curious device is used in this connection. The long iron rod is retained. It is bent, however, at right angles on the end, and this arm dips down into a clay vessel of cylindrical form. The bottom is closed, so that the vessel floats deeply in the molten glass. By manipulating the rod, the vessel is made to do the stirring instead of the rod itself. When the viscid condition is reached, the mass is permitted to solidify. Ordinarily, the crucible is sealed and left in the oven, the two to cool off together. After solidification, the crucible is broken open and the apparently good pieces of glass selected for tests as to optical qualities. If twenty per cent of the melt is usable, the manufacturer will be well satisfied.

There are special optical glasses which do not come under the lead and lime classifications. Various substances, such as bromic acid, phosphoric acid, fluorine, zinc and barium, have been pressed into service. The old crown and flint glasses have been surpassed in respect to the desirability of the refractive indices of the best of the newer products. Glass has been made containing absolutely no silicic acid. These types of glass are the result of the labors of the last 30 or 40 years.

Lenses of the commoner forms have binary combinations of plane, convex spherical and concave spherical surfaces. But the diverging types produced thus by no means exhaust the varieties now made and used for one optical purpose or another. In short, it has been found that the foregoing types did not cover all the requirements of defective vision. Thus, binary combinations of a cylindrical surface with plane and spherical surfaces have been found to produce lenses of distinct value to eyes unresponsive to the older forms. There is another type which demands notice. The convex member at the base of the ancient and classic architectural column—the member shaped like a doughnut or a life buoy—is called a *torus*. From this we have the adjective *toric*. Toric lenses are those having one surface agreeing in form with the convexity of the ancient torus. It is as if one bent a cylindrical surface so as to convert the rectilinear lines, called elements, to circular arcs.

The ordinary elliptical lenses for spectacles and the like are made from rectangular blanks about 1.76 x 1.36 inches in size. This size is regarded as especially economical. From it may be cut all sizes. Cylindrical lenses may be made from blanks 1.68 x 1.68 inches in size. However, it has been found possible to grind the axes of cylinders diagonally and thus produce from the standard size of blank what is often a much larger lens than could otherwise be cut from it.

An automatic machine sorts the blanks for lenses, thickness being the basis of separation. The various blanks are thrown into receptacles devoted to the several gages of thickness, the work being done so accurately that the error is below 0.01 inch.

The grinding of the blanks is accomplished by one large concern in the following manner: Warm pitch is employed as a thick surface coating of the grinding block. In this are placed a lot of the elliptical blanks. The block is given its covering of pitch by being pressed into a mold into which hot pitch has previously been poured. The block itself is preheated to facilitate matters. Upon cooling off, the block is withdrawn and the lenses, having in the meantime been heated on hot tables, are placed upon certain projections but in the layer of pitch. The block and its charge of blanks are now allowed to cool off, the pitch hardening and securing the blanks firmly in their respective positions.

The blanks are now ready to be ground. The block is set in place on the spindle of the grinding machine. That is, the exposed glass surfaces are now ground

(*Continued on page 116*)

# FAIRBANKS-MORSE

## Farm Comforts Through Modern Power

POWER on the farm has brought new comforts and conveniences to lighten labor and make rural life still more worth while.

The modern farm is lighted by electricity. Power from its Fairbanks-Morse light plant pumps water for domestic uses and for stock. It operates separators, churns, washers and other light farm machinery. The "Z" engine of this plant is the same engine that today is used by more than 250,000 progressive farmers.

Thousands of farms have several of these sturdy "Z" Engines helping to produce food for half the world. These quarter-million tireless mechanical farm hands are our answer to the farmer's problem of a serious labor shortage.

The reliance of farmers on Fairbanks-Morse products is but another indication of the inherent quality of these products—a quality of which the trade mark seal of this organization represents the objective.

Our products include Fairbanks Scales—oil engines—pumps—electric motors and generators—railway appliances and coaling stations—farm power machinery, such as "Z" Engines, lighting plants, water systems.

Advertising in this column is $1.00 a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

**PATENT FOR SALE**

PATENT pending in U. S. and Canada. A genuine novelty. Mallet Billiards played as ordinary billiards with a specially made mallet. The table is made 7 in. high, 13 by 7 feet, padded floor pneumatic cushions. Metal corners and side and end braces. Will be used in Clubs, Universities, Estates, private homes. It is played outdoors, under tents, summer houses, porches, etc. A healthy recreation, plenty of exercise. Will be more popular than golf or tennis. For information address inventor, Joseph Johnson, Box 583, Menlo Park, Calif.

**SPECIAL AUTOMATIC MACHINERY**

For any purpose invented and designed. F. M. ASHLEY & CO., P. O. Box 103, Chicago, and Tribune Bldg., New York. Established 1900.

**BUSINESS OPPORTUNITY**

SUBSTANTIAL manufacturing corporation wants capable men to establish branch and manage salesmen. $300 to $2000 necessary. Will allow expenses to Baltimore as explained. Address, Mr. Clemmer, 603 N. Eutaw St., Baltimore, Md.

**HELP WANTED**

PATENT Office Draftsman. State experience and salary desired. Munn & Co., 233 Broadway, New York City.

**NOVELTIES & PATENTED ARTICLES**
MANUFACTURED BY CONTRACT. PUNCHING DIES
LIGHT AUTOMOBILE STAMPINGS
E. KONIGSLOW STAMPING & TOOL WORKS, CLEVELAND, O.

**INSYDE TYRES**
—genuine inner armor for auto tires. Double mileage: prevent punctures and blowouts. Agents wanted.
American Accessories Co. Dept. 8 Cincinnati, Ohio

**We Will Make It**
Anything in a metal stamping or novelty produced from any metal and finished in any color.
Waterbury Button Co., Waterbury, Conn.

EXPRESS SERVICE
**MASON'S NEW PAT. WHIP HOIST**
Comparative cost 40 foot lift:
By elevator—5 men, 50 bales of wool per hour
By Mason's Whip—3 men, 90 bales of wool per hour
One rope hoists, lowers and holds the load
**Manufactured by VOLNEY W. MASON & CO., Inc.**
**Providence, R. I., U. S. A.**

**Hudson River Night Lines**
Daily from Pier 31, N. R., at Desbrosses St., weekdays 6 P. M. and 7 P. M. Sundays and Holidays, 6 P. M. and 9 P. M.; West 132nd St. half hour later (daylight saving time). Due Albany 6 o'clock following morning, Troy, 7.15 A. M. Direct rail connections to all points.

## Our Mechanical Eyes

(*Continued from page 114*)

against a spherical surface which forms the inner surface of a bowl. The abrasive material is emery powder or an equivalent. The larger grain sizes are first employed and then the smaller ones.

The next machine operation is that of polishing. Before or during this procedure, scratches may be discovered on the ground surfaces of the lenses. If so, the block must be ground again, as the removal of actual scratches is not a job for the polishing machine. A block with its complement of lenses perfectly ground is now set in or on a fixed holder in the polishing apparatus. The polisher rotates over the block polishing the various lenses by means of fine polishing material. The polisher is a shell having the same curve as the block and containing a lining of heavy felt which is cemented to the shell. The curvature of the block is vital and must be maintained. In hot weather this may be difficult or impossible to do, if the lenses are not kept moist and the temperature thus held down.

The lenses are now to be ground on the reverse side. The first step after removal from the old block is gaging for thickness, this dimension being now of very great importance, largely because one side is already finished. The grinding and the polishing are processes similar to what they were before. Inspection is, naturally, an important matter. If a lens is of first grade then it must show no defect within an ellipse 1.56 x 1.20 inches set within the lens size 1.76 x 1.36 inches.

It has already been noted that a residue of 20 per cent acceptable glass from a melt of lead optical glass is satisfactory to the manufacturer. But the percentage is often much less. Sometimes it is as low as 10 per cent or less. Here we have a reason for a higher price for lead optical glass than for commoner varieties of glass. All this is accentuated, when it is necessary to find glass for the objectives for great refractive telescopes. It is only rarely that a single block can be found which weighs as much as 100 pounds, if perfection in quality is desired. "A single fine vein, perhaps too small to be visible to the unaided eye, may be found to run through a whole block in such a way that it cannot be removed without breaking or cutting up the whole piece, and it will be seen that the frequency with which this is liable to occur increases with the volume of the piece required."

Lighthouse lenses are made from glass which is manufactured by a somewhat different process. Instead of letting the mass of molten glass cool down in bulk and break up into fragments, it is poured into iron molds which give it approximately the final form desired. It is then ground and polished to exact size and figure. Rings for annular lenses are produced up to 48 inches in diameter. Segmental rings are made of still larger diameter—up to 7 feet. Most lighthouse lenses are of lime glass, but for special purposes a dense flint glass is made with a higher refractive index.

## Learning by Seeing

(*Continued from page 107*)

of the cutlery works at Sheffield, England. Subsequently he has extended this original and initial idea until at present the index of motion picture subjects offered by the Holley organization includes practically every mechanical, medical, industrial, commercial and scientific activity adapted to portrayal by pictures. Recently Dr. Holley has made arrangements with the National Department of Agriculture so that, henceforward, he will distribute the interesting films of this government agency not only throughout America but to every nation under the sun which wishes to learn about more progressive systems of farming.

Matters of personal hygiene, first-aid systems of treating wounds, the care and nutrition of infants, methods of sanitation as well as the rudiments of the three R's are now taught by pictures, the six million odd mountaineers of the Appalachian Mountain belt being the beneficiaries. The films and motion picture equipment are carried into the mountains on mules, the creek bottoms and trails being impassable for other methods of transportation and railroads in those regions being few and far between.

Despite the fact that the Bureau of Commercial Economics has over 35,000,000 feet of negaitve in daily use, last year it was able to supply only 45 per cent of the requests for film which it received. The Americanization of our foreign born laboring classes is a matter of critical concern at the present time and for educational work of this description the motion pictures speak the universal language. They appeal forcibly to both literate and illiterate and for the visualization of current ideas and patriotic events in American history, the motion picture is the perfection of pictorial appeal. The educational "movies" provide wonderful short cuts and top speed processes for the tutelage of the immigrant classes.

Motion picture trucks—unique among the "movie" theaters in the universe which travel from point to point in the rural districts of various foreign countries—carry the teachings of filmdom to millions of peoples each year. One of the trucks is on the Island of Sumatra off the Malay Peninsula where tens of thousands of natives work on the rubber plantations. Another outfit at Singapore furnishes highly prized amusement to the local laborers. The natives of the Island of Java sit about on mats, chewing betel nuts as they watch the marvelous picture shows which the "movie" truck provides for their entertainment. Other similar outfits are operated on the Island of Ceylon and in the Levant. The Bureau also maintains a film service which displays pictures on many of the river steamers in Russia in coöperation with the Siberian Steamship Company. In addition the Bureau has over 600 established centers in Latin-America, the chief difficulty being to supply sufficient negative to satisfy the continuous demands from Argentina, Bolivia, Chili, Mexico, Brazil and Nicaragua.

## The Heavens in August, 1920

(*Continued from page 109*)

use of mariners. The predictions made in this way are very good, except when exceptional weather conditions—such as a gale blowing the waters of a long bay or estuary toward one end—introduce unpredictable complications. It is probable, however, that only a small proportion of the mariners who make use of these predictions have any idea how they are made.

### The Heavens

The principal constellations are so clearly shown on our map that no long discussion is necessary. Cygnus and Lyra are right overhead, at the hours tabulated below the map for the different dates. Aquila, Sagittarius and Scorpio lie to the south and southwest, along the brightest part of the Milky Way. Ophiuchus, Hercules and Bootes are in the west and southwest, Draco and Ursa Major in the northwest. Cassiopeia and Cepheus are in the northeast, with Perseus rising below. Pegasus and Andromeda are high in the east, Aquarius and Capricornus in the southeast, and Fomalhaut below them.

### The Planets

Mercury is a morning star and is best to be seen about the middle of the month, when he rises at 3:45 A. M. (standard time).

Venus is an evening star, setting from half to three-quarters of an hour after sunset, and hard to see.

Mars is in Libra, and comes into quadrature with the sun on the 3rd, after which he may be considered an evening star, though he remains in sight until between 10 and 11 P. M.

Jupiter is an evening star at the beginning of the month, though too near the sun to be easily seen, but passes through conjunction on the 22nd, to reappear as a morning star next month. Thus we have the final breaking up of that brilliant combination of the three planets Mars, Jupiter and Saturn which has given the evening skies in this part of the world such unaccustomed brilliancy during the spring and early summer.

Saturn too is an evening star, setting an hour later than the sun in the middle of the month.

Uranus is in opposition on the 27th. He is then in Aquarius, in 22h. 23m. 34s. R. A., and 10° 54′ south declination, and is moving 9s. west and 52″ south per day. There are no convenient stars nearby to serve as guides, and he can best be identified with the aid of a good star map.

Neptune is in conjunction with the sun on the 3rd, and is invisible this month.

The moon is in the last quarter at 8 A. M. on the 7th, new at 11 P. M. on the 13th, in her first quarter at 6 A. M. on the 21st, and full at 8 A. M. on the 29th. She is in apogee on the 24th, and in perigee on the 12th—near new moon, so that high and low tides may be anticipated.

During the month she passes near Uranus on the 2nd, Mercury on the 12th, Neptune on the 13th, Jupiter and Venus on the 14th, Saturn on the 15th, Mars on the 20th, and Uranus again on the 29th.

On the afternoon of the 8th, Venus and Jupiter are in conjunction and only 40′ apart. This would be a handsome conjunction if the planets were not so near the sun that they will be very hard to see.

Clark's Island, Plymouth, Mass.

## The America's Cup Races

(*Continued from page 108*)

footed faster. Every yachtsman knows what that means. The "Resolute," beautifully sailed by Charles Francis Adams, turned the outer mark with a lead of 2 minutes 4 seconds, and down the wind "Shamrock" beat her by exactly that amount.

That two yachts of such radically different design should sail for a distance (actual) of 37 miles at an average speed of 9 knots and finish in a dead heat, is unique, surely, in the annals of yachting.

The "Resolute" won, therefore, by exactly her time allowance of 7 minutes 1 second.

If the cup is to remain in the custody of the New York Yacht Club, "Resolute" must now win two races, straight.

## Australian "Blackboy" Tree

A PECULIAR product of the vegetable world is what is known as the "blackboy" tree which flourishes in the state of western Australia. It is, in fact, a species of the grass tree, and grows to a normal height of 7 to 10 feet, and is found to be useful for a variety of purposes.

Until recently no attempt has been made to utilize the tree commercially, but a company has now been formed to work and market its by-products. The plant consists of 19 sets of retorts and furnaces, condensers, receiving tanks, etc., and can deal with 100 tons of gum and other material derived from the tree. The company at present employs about 20 men, besides cutters, and among other things being produced are tars (free from harmful acids), tarpaulin dressings, rope tar, and sanitary tar, lacquers (such as Japan black), steam and refrigerating pipe lagging, paint for ironwork that requires stoving at high temperature, stains and paints, pitches for marine insulating, phenol, benzol, and alcohols, coke, potash, and pyrogeneous acid. The production of dyes, perfumes, and formalin, and various kinds of varnishes is also planned.

# Self-Starters That Start

Hidden in the midst of that mysterious thing, your self-starter, is a centre and source of joy or gloom. It is the coil. On it depends the action of your self-starter. On this page is printed a list of cars whose lighting, starting, and ignition are insured by the use of Acme Magnet Wire or Acme Wire Coils. It is well for you if your car has the unseen service of Acme Wire.

Whether it is your automobile starter or vacuum cleaner, your electric meter or doorbell, wherever electric current does work for you, *the coil is the vital thing.*

If it's an Acme Wire Coil you're sure of it.

*Acme Wire—It goes in the space*

Our new catalog tells all about Acme Wire Products, and shows why the leading manufacturers of electrical devices use them. Write for it.

S.S. NIELS NIELSEN MAKING HER TRIAL RUN

S.S. SUCROSA SISTER SHIP OF THE MILERO

# Over a Million Miles Without a Failure

BEFORE the war had forced factories into a reckless rush, the General Electric Company equipped the steamships:

| | | |
|---|---|---|
| Pacific | Sucrosa | Hanna Nielsen and |
| Eurana | Niels Nielsen | Milero |

with Curtis Turbines and two-plane Marine Gears of the double reduction type which this company introduced to the world.

Every one of these vessels has made a proud record. Their combined mileage on June 1st totalled 1,057,326 miles.

In the ports of the world today the propelling equipment in every one of them, except the tanker Milero which sank in a storm after three perfect years, is gaining repute for reliability, efficiency, economy and flexibility of operation. They are first rate ships and their

***G-E Marine Geared Turbines Have Made Good***

This pre-war type of equipment was successful, but not satisfied with that, the G-E Company's engineers have found ways of improving it.

Gear tooth shapes have been altered and pressures decreased 15 to 33 per cent, gear length over all has been lessened, sturdy weight has been added and a higher degree of flexibility attained in the gears by slip type pin couplings with floating bushings.

The gear lubricating system has been improved. Casings have been made more rigid and hinged covers of ample size give greater accessibility for inspection.

**G-E Marine Geared Turbine Record in U. S. Merchant Marine**

Units now in service 280 D. W. Tonnage 2,524,529
H. P. Capacity 681,600 Miles Traveled 13,702,000

The nation had 144 marine geared turbine merchant ships in operation during the war—G-E equipment on 95 rendered 81 per cent of the total service.

Made in standard sizes from 2000 to 4000 H. P., the 1920 two-plane type double reduction Marine Gear is

# How Little Dollars Save Big Ones

MANY a truck owner has adopted his most profitable transportation ideas from the practice of the great railroads.

On *maintenance*, for example. The railroad sends its rolling stock into the shops every so many miles. Not because something *is* the matter. But so something *won't be*.

That is how a railroad keeps its rolling stock in prime condition—and the little dollar today saves the big dollar next year.

* * *

"I know that all machinery wears," says the truck purchaser; "but not so much with regular care. What sort of maintenance organization will you place behind my truck?"

Packard has definitely organized its Service facilities to keep maintenance expense of Packard trucks at the very lowest point.

None but the better mechanics of every trade are employed at Packard Service Stations. They are given machinery that augments their skill and facilitates their work.

Of first importance is *expert judgment*. What can a mechanic at half the price save an owner if he takes twice as long to find the trouble?

TODAY Packard service stations everywhere have in operation Uniform Service Methods — Uniform Stock-keeping Methods — a definite system to eliminate haphazard, time-consuming practice in repair shops.

More than one hundred repair operations have been standardized —workmanship improved and time reduced.

This system is solely Packard. There is nothing similar.

A maximum cost estimate of repairs and replacements is presented to the customer for approval before the work is started.

Packard Service is designed to apply the *ounce of prevention*. Packard understands perfectly that economy of maintenance of its trucks in daily use is the greatest factor in creating sales for new Packard Trucks.

Many Packard owners attend to truck maintenance on a set schedule. *A given day in each month for the truck to spend at the service station.*

These owners reduce maintenance cost—get the fullest advantage of Packard's 44 factors of engineering superiority—receive to the utmost the benefit of the long life built into every Packard Truck.

## Fair Weather Yachts

ALTHOUGH the failure of "Resolute" and "Shamrock" to race in a 22-knot breeze and a tumbling sea on Saturday, July 24th, was a keen disappointment to yachtsmen who were rejoicing in the prospect of a battle royal to windward between the Cup yachts, the incident cannot fail to have a beneficial effect upon the future of such international contests; for it has served to emphasize once more the fact that scantling has been reduced and sail area increased to such a degree that the boats built to compete for the Cup are no longer seaworthy.

The conditions on Saturday were such as to justify the skippers of the two yachts and the Race Committee in calling off the contest. The wind, by the time the boats reached the starting line, was about 22 knots with a possible 28 knots in the puffs; but it was the steep and confused sea that constituted the danger. In broad reaching from Sandy Hook to the Lightship, both boats labored heavily, and the moment they came up in the wind, it was seen that the seas were so short that in a thrash to the outer mark, these fast moving boats would be heavily punished. Furthermore, they have no bulwarks and have nothing more than small, longitudinal cleats on which the crew can find a footing. The seas would have swept the boats fore and aft, and even if hull framing had held and masts had not gone by the board, it is more than likely that in a fifteen-mile thrash to windward, men would have been swept from the decks.

And yet the day was one that would have rejoiced the hearts of the men who sailed the sloops and cutters of thirty to forty years ago on this same historic Sandy Hook course. There comes to mind the classic race between "Puritan" and "Genesta," when the wind blew twenty knots at the start, and "Puritan" sent down her topmast and "Genesta" substituted a jib-headed topsail for her club topsail in the fifteen-mile beat back to the finish. Says the chronicler of that time, Mr. Winfield Thompson, "The wind was now squally . . . both yachts were sailing with their lee rails under water, their decks awash, the wind blowing at the rate of nearly thirty knots an hour, which caused an ugly sea."

The moral of this incident is that America should join all the other countries of the world in the adoption of the rule which is producing fast and seaworthy yachts that are serviceable alike both for racing and cruising. Unless a rule specifies a limit of lightness beyond which the designer must not go in any given class, clever designers, such as Herreshoff and Nicholson, will always find a way to build extremely fast and over-light boats, and yet keep within the rule. Under such a rule that staunch and very beautiful yacht, the 23-meter "Shamrock" was built. This craft has full cruising accommodations, is extremely staunch in construction, and has a turn of speed sufficient to satisfy the most exacting demands of the racing enthusiasts. She would have revelled in the weather conditions of Saturday. Our own rule produces a wholesome boat as regards form and sailspread, but it fails to set a limit upon light construction, and the result was seen on Saturday when "Resolute," in common with "Shamrock," was unwilling to face the music. It is for us, in common with the yachting nations of all the world, to set a ban upon freak construction, and build to a universally adopted rule which will enable our yachts to compete with yachts anywhere in the world, under similar conditions, at whatever port she may call.

## Wood as a Structural Material

SHORTLY before the war one of our leading bridge engineers made the statement that, in view of the enormous consumption of steel and the multiplying rate at which it was proceeding, the time would come when we should be threatened with a shortage of this material. Among the comparatively modern constructions which have made a heavy inroad upon our supplies of iron ore, he mentioned the towering office, hotel and apartment buildings, which, before the war, were being built by the thousand throughout the country. The enormous expansion in our industries has created a proportionate demand for tructural steel; and although the growing use of concrete has served to lessen the demand, the steel reenforcement foots up a heavy annual total. Although the building trades are passing through a period of stagnation, the reduced consumption of steel, due to this, is temporary and it will be more than counterbalanced by the tremendous demand that will ensue when normal conditions return, and we attempt to make good the arrears of construction.

As for the railroads, the largest part of the billions of dollars which will be required as a consequence of the neglect of the past half dozen years will be spent upon steel in the shape of rails and steel rolling stock. Moreover the great revival in our merchant marine, which we all hope will prove to be permanent, will call for heavy deliveries of shapes and ship plates—a demand which before the war was insignificant.

All of which suggests the wisdom of casting our eyes about in search of substitutes for steel, which can compete with it in cost and durability; and the first material that comes to mind is the wood of which we still have such a potential store in our sadly depleted but still magnificent forests.

Leaving out of consideration the extensive use of wood for home building, we are apt to forget how greatly we were indebted, in the earlier decades of our industrial progress, to our timber supplies for the construction of our factories, the marvelous post-war extension of our railroad system, and the construction of the famous clipper ships of our merchant marine. As regards the construction of our transcontinental railroads with their many ramifications, it is no exaggeration to say that, had it not been for the superb Douglas fir of the West and the long-leaf yellow pine of the South, the pioneer railroads of the last century could never have been pushed out over the continent at the amazing speed and for the very low cost which characterized their construction.

The Howe Truss timber bridge and timber viaduct—without these our pioneer railroad builders would have been helpless. For in those days, steel mills were few and steel was costly; whereas, once the Mississippi Valley was crossed the engineer found himself within easy reach if not in the very midst of vast forests of the finest structural timber in the world. All that was necessary for the crossing of rivers and the spanning of deep ravines was to erect a sawmill in the adjoining or nearby forest, and send east a bill of steel, consisting of screwbolts for his timber trestles and round bars for the tension members of his Howe Truss bridges, together with some simple castings for the footing of the compression members.

But all that was long, long ago; whereas our object is to suggest that there are many forms of construction in which we might turn once more to wood and get excellent results. Nor should the deplorable outcome of our recent attempt to build a fleet of wooden ships be allowed to shut the door upon wooden shipbuilding. Timber that was standing in the forest one month was framed into a ship the next—and ships that were built of green wood had only one fate in store for them.

But it is far from proved that there is no place for the wooden ship on the high seas. Yacht Designer Nicholson, who has produced a staunch and tight boat in "Shamrock," believes that the multi-ply system can be used on ocean-going ships, and that by sawing the timber into planks for "ply" construction, the wood can be so rapidly seasoned as to make it possible to reduce the time between the felling of the timber and its incorporation in the hull to a practicable limit.

As to the durability of timber, there are county wooden bridges doing good service, even today, that must have seen a good "three score years and ten" of service in the open, and there are timber roofs above the vaulted masonry roofs of European cathedrals that have stood untouched and perfectly sound for centuries.

## Re-Stocking Our National Resources

OUR national life these days seems to be little more than one worry after another. One day we hear that gasoline will soon be unknown; the next day we read that farmers are raising insufficient food and that we face an early famine; another day it is a coal shortage that stares us in the face; comes another day and it is our disappearing forests. Calamity threatens on all sides, to be sure.

These conditions are not something of the moment. We are always too ready to blame the recent war for our latest worries; and the shortage in production and our depleted resources are almost invariably charged up to our late military efforts. Yet the truth of the entire matter is that the world has long been living in the present, with little or no thought for the future. Thus forests have been cut down without consideration of the morrow; new ways and means of consuming petroleum products have developed without end; warehouses have been drained of their accumulated foodstuffs; coal reserves have been taken while waiting for improved transportation conditions. It is this matter of hand-to-mouth living that is to blame for our present predicament; and in this particular we are perhaps the worst offenders to be found anywhere.

The time has come for an accounting—for a national inventory so to speak. The various Bureaus of the Government, the leading industrial associations, and the large manufacturing organizations have taken a share in this inventory. For the first time these parties are seriously and exhaustively going through the cupboards of the nation in order to determine just what stocks we still can count upon in the form of natural resources. And the facts and figures of this nation-wide inventory are being passed on to the man in the street since he, as the ultimate consumer, must know why things are not as plentiful and inexpensive as they used to be. Furthermore, said man in the street must be taught to moderate his appetite for those things which he formerly considered inexhaustible.

For example: Our most pressing conservation question relates to our forests. Out of 850 million acres of virgin timber we have but 150 million left. We have effectually exhausted the timber lands of the Northeast and of the once magnificent forest States of Pennsylvania, Wisconsin and Minnesota. About ten years will see the Southeast, which has been our greatest producer of saw timber for years, out of the running as a serious competitor in the lumber markets. Already much of the timber for the thickly populated East and Middle West comes from beyond the Rockies.

Facts such as these are interesting, vitally interesting. They should receive wide circulation among thinking men. Such knowledge leads to a better understanding of present industrial conditions, and in a great measure must hasten and perfect the various phases of our gigantic re-stocking scheme which alone can ward off the several calamities with which we are threatened. The SCIENTIFIC AMERICAN has always made it a point to study all questions having to do with the welfare of these United States. Its editors have long foreseen the advent of this day when a nation-wide inventory would confront the people with cold, harsh facts about depleted resources and the urgent need of immediate conservation and replenishment.

Elsewhere in this issue there is a story of what takes place in the wake of the woodsman. It is a depressing story. It tells of the man-made deserts to be found in this country, where formerly there flourished the finest forests to be found anywhere. It tells of man-made floods which must now be combated with elaborate and costly dams. But it is a story that must be told if we are to avoid the mistakes of yesterday and to re-stock the nation's shelves.

## Electricity

**To Make Wood Acid Proof.**—Some storage batteries are carried in wooden battery boxes on cars and annoy the owners by leaking or slopping of the acid. To make the wood acid proof take six parts of wood tar and 12 parts resin, and melt them together in an iron kettle, after which stir in eight parts of finely powdered brick dust. The surface to be covered must be thoroughly cleaned and dried before painting with the warm preparation.

**Non-Leaking Storage Battery.**—A new storage battery said to be absolutely non-leaking has been produced. It has a special valve to let off the explosive gas, so arranged that no acid can get out. The plates are separated by strips of wood which not only prevent short-circuiting inside the cell, but retain the acid when the storage battery is upside down, giving an electrical efficiency of 75 per cent in this position. This battery is a German invention.

**Cable Construction.**—Despite the great development of wireless telegraphy, submarine cables are still being constructed, and with the great increase in commercial and journalistic messages are still regarded as a necessary alternative to wireless, and by no means obsolete or likely to fall into disuse. In fact, a new cable to the Far East from Great Britain through the Mediterranean, involving a length of 7,000 miles, is being laid section by section as ready, while the possibility of a new cable from Vancouver to Fanning Island is now being discussed.

**Electric Signals for Guiding Ships.**—In a recent French periodical there appears a description of a French method for guiding ships in foggy weather through narrow channels, harbors and so on. The method consists essentially in feeding with alternating current submarine cables or cables laid in the air along the piers and in observing on board ship the positions of said cables by the aid of frames connected to telephones. The frame can be rotated around an axis parallel to the fore-and-aft line of the ship, so that it can be ascertained if the cable is "starboard" or "port" of the ship.

**Hydro-Electric Development in Ceylon.**—It is reported that Ceylon has again taken up the work of investigating its widespread hydroelectric resources, which work was delayed by the war, and it is expected arrangements will proceed rapidly for the early initiation of the proposed electrification of the island's industries and the partial transformation of the transportation systems from steam to electricity, including the extension and development of the use of electricity for domestic purposes in Colombo and other centers of population. Although the standard American frequency of 60 cycles has been prevalently employed in eastern countries during recent years, the electrical adviser to the Government of India, who was lent to the Government of Ceylon to study the above projects, strongly recommends the British standard of 50 cycles, and states in his report that it is confidently anticipated that the consulting engineers employed to draw up the specifications will be able to place the order for the equipment within the British Empire.

**Suspension Insulators.**—Notwithstanding the recent improvements in porcelain insulators, failures are sufficiently common so that allowance must be made for them. A certain factor of safety is required, in the shape of extra insulation, to provide for the electrical unreliability of the insulators themselves apart from conditions of abnormal operating stresses. There are a wide variety of operating conditions which affect the amount of over-insulation required, and after having found the minimum number of insulators per string required for any given operating condition, Mr. A. M. Klamber, in a paper read before the American Institute of Electrical Engineers, points out a method of determining the amount of extra insulation desirable from an insurance standpoint according to the law of probabilities. Equations are developed from which the probability of failure for any given case or the ratio between such probabilities for any pair of cases may be determined directly. A numerical example is also given which shows the development of the theory of minimum annual cost for combined mechanical and electrical failures.

## Science

**An Entomological Expedition from Cornell University,** led by Prof. J. Chester Bradley, is spending a year in the collection and study of insects over a very extensive itinerary in South America. Most of the countries on that continent will be visited.

**A Memorial to Sir William Osler.**—Funds are being raised in Great Britain and the United States to provide a memorial to the late Sir William Osler. This will probably take the form of an Osler Institute of General Pathology and Preventive Medicine. Dr. Harvey Cushing, of Peter Bent Brigham Hospital, Boston, Mass., has been requested by Lady Osler to prepare a biography of her late husband, and announces that he will be grateful to anyone who will send him either letters or copies of letters, or personal reminiscences, or advise him of others who might be able to supply such information.

**Army Mental Tests in Schools.**—The National Research Council announces that the mental tests which were used with striking success in the Army during the war are to be used on a large scale in American public schools. A program of group tests has been worked out which will make it possible to conduct wholesale surveys of schools annually, or even semi-annually, so that grade classification and individual educational treatment can be adjusted with desirable frequency. Prof. R. M. Yerkes is in charge of this undertaking, and the General Education Board is furnishing financial support.

**The Cathode-Ray Oscillograph**—In a note on its investigations of this instrument, the Bureau of Standards points out the unique value of the cathode-ray tube as a means of studying the excessively rapid alternations and fluctuations of the electric currents used in radiotelegraphy. The Bureau states that this form of oscillograph can now be designed and constructed with a considerable degree of certainty to suit a variety of different operating requirements. The device is a valuable aid in the standardization of wavemeters, and in the determination of wave forms produced by spark and other types of radio generators. Its most conspicuous usefulness is in the study of the characteristics and behavior of electron tubes, as detectors and generators of current for radio purposes. As an implement of research, permitting visual observation of phenomena previously unseen and furnishing data for new ideas and theories, the cathode-ray oscillograph performs a service that can be achieved by no other device. The Bureau will eventually publish a Scientific Paper on these tubes.

**Susceptibility to "Ivy" Poisoning.**—In the disgraceful chaos of popular plant nomenclature—which English-speaking botanists ought to set in order at the earliest possible moment—a certain species of the genus *Rhus*, neither related to nor resembling ivy, is known as "poison ivy." Having thus relieved our feelings, we proceed to say that a valuable paper on the subject of "Ivy and Sumac Poisoning" has recently appeared in the *Public Health Reports*, and will, presumably, be distributed in separate form by the Public Health Service, Washington, D. C., to a great many applicants for information on this important subject. The authors are Drs. E. A. Sweet and C. V. Grant. One feature of the paper that seems especially worth quoting here relates to the question of susceptibility. It is well known that many people regard themselves as immune to the poisonous effects of "ivy," boasting of their ability to pull it up with their bare hands, etc. It appears, however, that experiments with persons of this type show that when they are subjected to prolonged exposure, or to the application of the toxic principle of the plant itself, they react to some degree, and are therefore not immune. Though varying degrees of susceptibility to the poison exist, a person may be repeatedly exposed without noticeable symptoms, only to have his pride humbled on a subsequent exposure. Some persons not ordinarily susceptible to "ivy" react to poison sumac (*Rhus vernix L.*). Moreover, certain persons who claim to be insusceptible to the effects of the leaves admit that smoke from the burning plant, which contains a finely divided but heavy dosage of the toxin, causes symptoms. The plants are most poisonous in the spring and summer.

## Automobile

**Use Current Sparingly in Winter.**—Do not connect additional apparatus, such as electrical horns, cigar lighters, etc., to the system without taking the matter up with the factory. The surplus capacity of the system is large but there is a limit to the amount of current which the generator can produce. Use the same judgment and reason in the operation of the electric lights on a car as you do those in your home or garage. When a car is running it is not necessary to burn all the lights, the two heads and the tail are all that are required or that are of any service. When the car is standing at night, use the side and tail lights only.

**Trucks for Forest Service.**—The United States Forest Service has lately gone on record as in favor of the employment of motor trucks for the gruelling service in the national forests. Chief Henry S. Graves of the Forest Service does not feel that the time has yet come for the government to outfit with passenger cars the forest rangers and other officials in charge of the national forests but for heavy transportation work in the forests, particularly when the fire menace looms, he is unqualifiedly in favor of motor trucks. On this score he recently outlined his position as follows: "I believe it will be desirable in the long run to have motor trucks in the forests where the hazard of fire is large for transporting materials and men to fires and for similar work."

**A New Gasoline Street Car.**—The preliminary test of a new type street car devised by a well-known auto and tractor builder at the shops in Dearborn, Mich., was declared to be a complete success. The new type of car will leave ahead of the Wolverine Flyer, between Detroit and Chicago, and will race it for a time record over the tracks of the Michigan Central Railroad, and in order to be successful will have to make 70 miles per hour. The power unit which will move the car represents a new combination of functions. It is a motor, an air compressor, an electrical generator, and a heating and lighting plant all in one. All operations necessary for the control of the car are centered in the motor. All this is accomplished, it is said, with a 75 per cent reduction in weight, as compared with the power and control equipment of the ordinary electric car.

**Extremely Light Auto Body.**—Mention has been previously made in these columns of the influence of automobile engine design principles on the development of the aerial power plant and now we find that aerial designers are contributing to the refinement of automobile construction, especially as relates to body construction. Our contemporary, *Automotive Industries*, describes a special five-passenger Sedan body which is claimed to weigh only 120 pounds for a car of 112 inches wheelbase. These bodies are constructed on airplane fuselage principles and are of a three-ply veneer combination. The great strength and light weight of plywood permits it to act as a sheathing and at the same time contribute considerably to the strength of the structure. The veneers usually employed consist of two plies of birch with a ply of mahogany between. The thickness of the material used in the construction of the conventional auto body is one-eighth of an inch.

**Motor Transportation in Palestine.**—The camel is being superseded by the motor vehicle and soon cars and trucks will be numerous in the streets of Jerusalem and other ancient cities of Palestine as well as being employed for interurban transportation. The slow moving, but fairly reliable, camel is to be replaced by the faster and more reliable motor truck mechanism. The problem of transportation not only in Jerusalem but throughout Palestine is acute. The railroads are few in number and uncertain in their schedules. Most of the passenger service of these roads was suspended during the war except for the use of troops. These roads are now in such a condition as to make other means of transportation necessary. The English since their occupation have been building up the important ports of Palestine and are planning to operate a fleet of motor trucks to these places to accommodate the influx of tourists to the birthplace of Christianity and to accommodate commercial travelers. A service from Jerusalem to Damascus in Syria is also being planned.

# In the Wake of the Woodsman

## The Great American Formula for Converting Forests Into Deserts

By H. A. Mount

THIS country is suffering a rude awakening just now to the fact that our forests are fast disappearing. This is chiefly due to the fact that our daily newspapers have been hardest hit through the restriction of their paper supply and they have become very willing spreaders of a much-needed propaganda.

We all dislike the calamity howler. As long as our favorite daily paper comes out on time and in its usual proportions we are likely to pay little attention to the front-page announcement that the supply of pulp wood in the United States is three-fifths gone, and that we are now dependent on Canada for two-thirds of our paper. And what if our Department of Agriculture solemnly warns us that unless we stop wasting our forests they will be gone in another fifty years? Fifty years—plenty of time to find a remedy and what's our Department of Agriculture for, anyway?

But there are times when optimism amounts to bad judgment and the man who pretends optimism about our national forests is poking his head in the sand. We need not wait a half century to see the results of a wasteful use of our forests and the lack of governmental care.

China's example is notorious. Once her lands were just as fertile and her forests just as "inexhaustible" as our own. Today these same vast areas are deserts that support no life—animal or vegetable. The reason is that China cut off her forests with the same reckless abandon with which we are destroying ours.

But we need not go to China for a horrible example. We have within our own boundaries the beginnings of deserts that are the direct result of cutting off our forests and subsequently neglecting the land. In two former articles we have dealt with the effect on our industries of our diminishing forests. In this one we shall consider the result to the land. This constitutes a more potent threat to the nation's future than any possible harm to industry, because it affects the fertility of the soil, the flow of rivers, the winds, the very climate of the continent. We can already begin to see bad effects, but appeals to stop the destruction so far haye fallen on deaf ears.

There is hardly a spot in the United States where one needs to go farther than ten miles from home to find examples of the erosion of the soil that follows cutting of woods from hillsides. From these it is easy to imagine the widespread devastation that comes from cutting off the timber of large mountain areas and then allowing the remaining vegetation to be killed off by repeated fires. There are many such areas in this country. Some of them have been standing barren for thirty years or more and are already potential deserts. Most of them have simply been rendered worthless and have been abandoned.

In the Manti national forest of Utah there are two eroded areas of nearly 50,000 acres each. Parts of North Carolina that once were cultivated now are eroded and abandoned. All over the New England States are small areas abandoned because of erosion.

"Every drop of rain that falls on more or less exposed soil," says a bulletin of our Department of Agriculture, "has the power of removing soil particles, and with them the soluble salts essential to plant growth."

Trees and plants break the force of falling rain and form reservoirs which prevent the water from forming rivulets which might cut deep gullies in the soil. The leaves and stems of plants and trees drip water for some time after a shower. The roots form a path of entrance to the soil and give the earth a spongy quality.

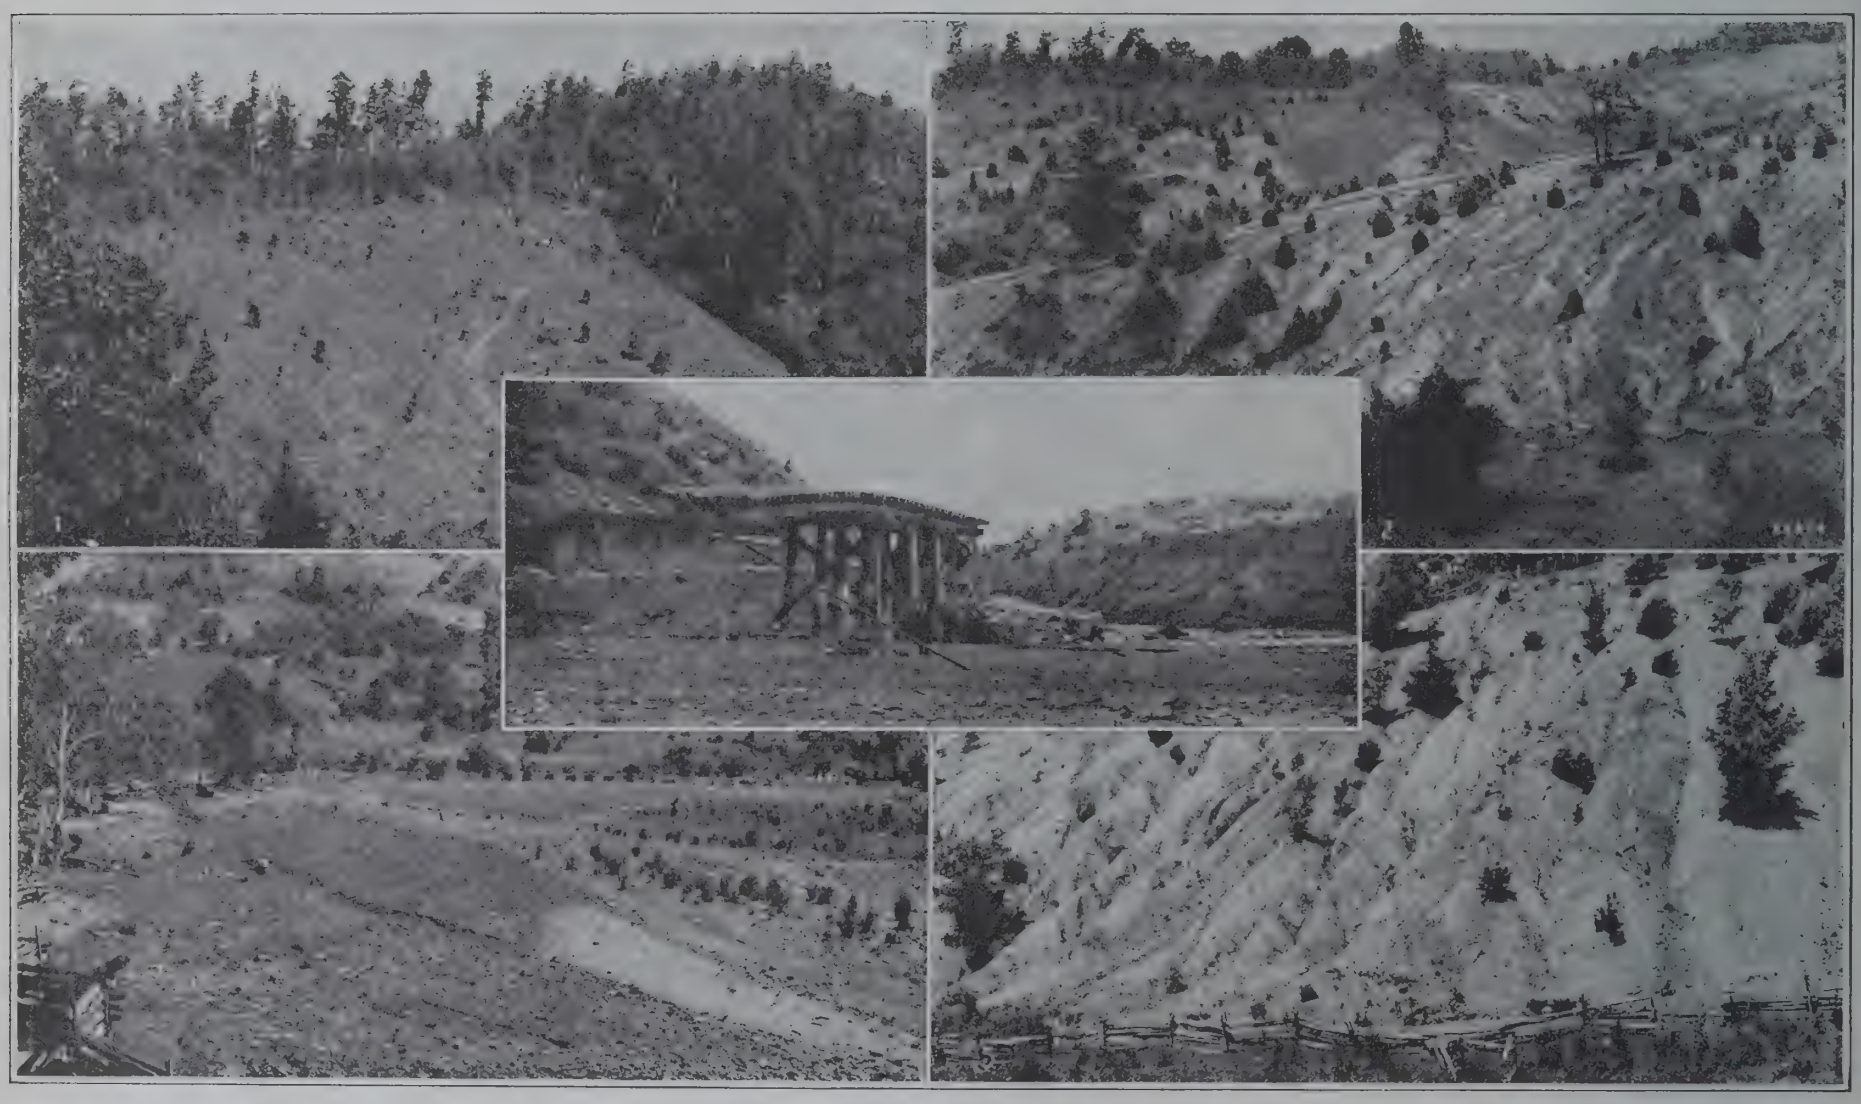
If the vegetation is gone the water quickly flows off, carrying with it part of the soil, and leaving behind stones and rock. As the waters combine and gather force their destructiveness increases. Creeks and rivers are overflowed and roads, power plants, property and even lives are destroyed.

China sees an extreme of this condition every year in the floods of her great Yellow River. Thousands of lives and countless millions of dollars' worth of property have been destroyed by this one river. In this country the Yellow River has a promising understudy in the Ohio. Nearly every year Pittsburgh and Cincinnati and many other towns and cities on its banks are flooded with disastrous results, principally because the forests of the West Virginia mountains, where the Ohio River has its headwaters, have been cut down.

The effects of erosion are not felt so keenly in the East as in the West, however. In some districts which depend on a natural watershed for a continuous supply of irrigation water, the flow has become erratic through erosion of the soil. Spring freshets send tumbling down into the irrigation ditches a great quantity of water, but in the summer when water is most needed the streams are almost dry. Many live-stock growers have made the discovery too late that cool forest shade and running streams in summer are almost indispensable to them.

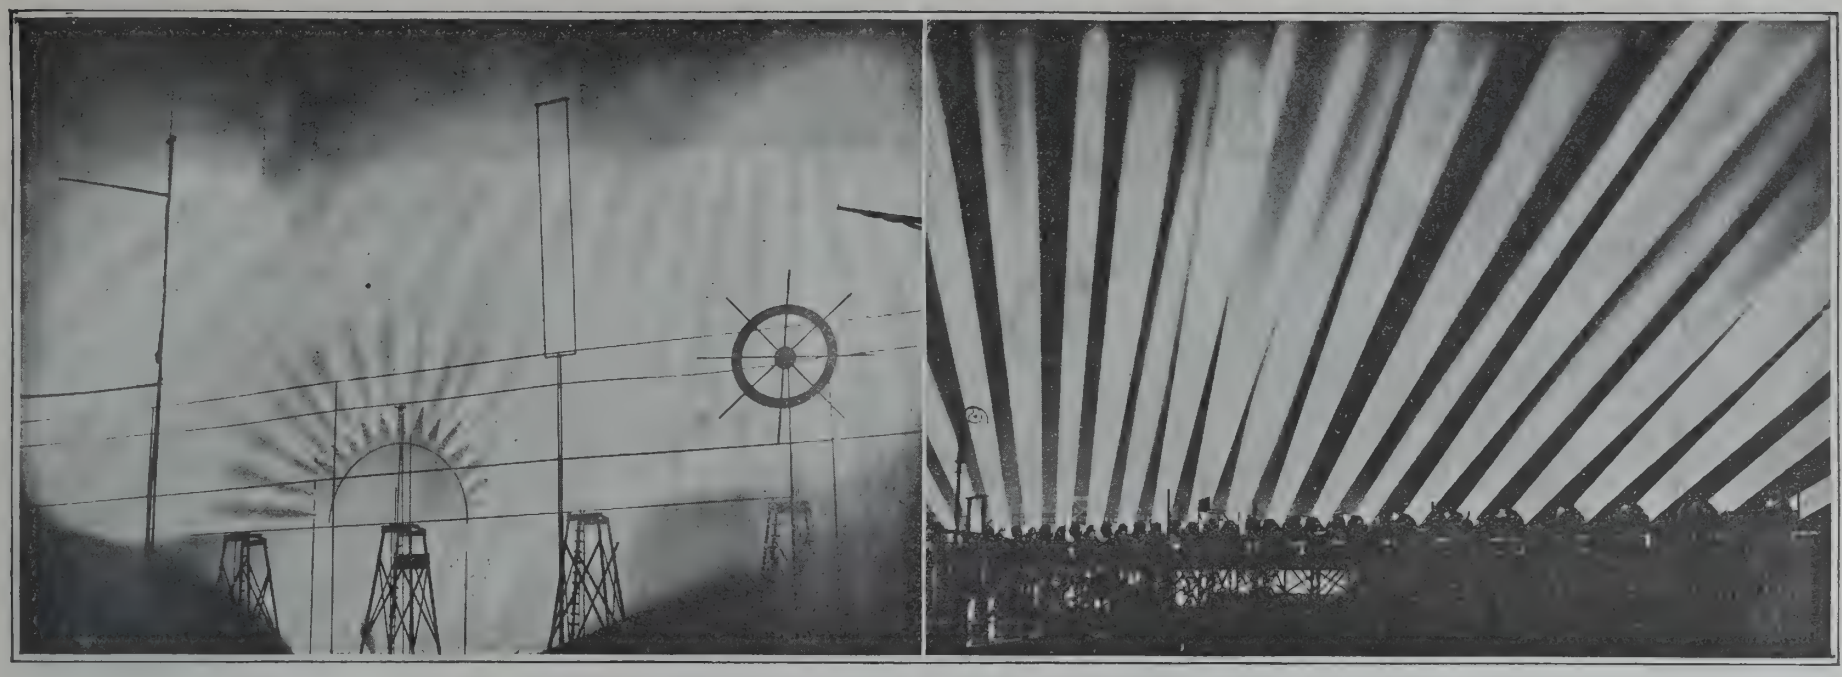
The worst feature of erosion is that the land is not simply denuded of its vegetation and gullied by rain, but the very fertility of the soil is destroyed. It will not support the plants which once grew on it

(*Continued on page 137*)



1. Very steep, rocky, washed land formerly cultivated in tobacco. North Carolina. 2. Deep gullies on abandoned hillside land on tributaries of Cane Creek, Mitchell County, North Carolina. White pine is slowly restocking this area, but the erosion is so rapid that seedlings with difficulty secure a permanent foothold. 3. Trout Creek, about five miles from Buena Vista, Colorado. Trestle of railroad left standing in midstream after washout in spring. 4. A seven-acre field badly washed by freshets. The top soil was eroded to a depth of from one to three feet in broad channels across the bottom. Where the soil has been eroded it is too rocky and sandy for cultivation. The land had just been plowed and planted in corn, and the lines of the furrows can be clearly seen in the unwashed place in the middle of the foreground. 5. Eroded slopes in North Carolina.

**Some examples—and there are hundreds of others—of what happens in regions where the woodsman's axe has been freely used**



*Left:* Some of the "fireless fireworks" effects produced by means of steam and incandescent searchlights *Right:* A battery of incandescent searchlights.

**Two striking examples of what may be done with the incandescent searchlight**

## The Last Word in Searchlights

**By E. W. Davidson**

IMAGINE attaching a searchlight to the lighting circuit in your house some night and throwing a beam so powerful that a man standing a mile away in this beam would have light enough to read a newspaper. It can be done. This is not to say it will be done often, however, for various protective devices would be necessary. But the incandescent searchlight which can operate on either an alternating- or direct-current circuit with proper auxiliary devices has established itself, replacing arcs of medium size for many purposes.

The first use of the new type of searchlight for spectacular effect was made at Saratoga Springs on the night of June 19 when that city turned on its new street lighting system in the midst of an illumination carnival. The powerful beams of 18 searchlights, playing through the heavens that night, were cast by incandescent lamps—a fact unknown to most of the thousands who witnessed the celebration.

These 18 beams wrought skilfully produced columns and curtains of steam into great, soft-tinted phosphorescent fans and plumes. They streaked the black sky with beauty, tracing bombs up into the night and dyeing little clouds of powder smoke with variegated tints. They turned the glare of ordinary fireworks into a radiant effulgence such as few Saratogans had ever seen. Their brilliant light helped make memorable the Saratoga festival of light.

But their use is by no means limited to gay, spectacular illumination. The incandescent is fast replacing the arc in searchlights of the type used by river steamers and coastwise vessels. Where a tower or high building facade is to be flood-lighted, the incandescent searchlight supplies accurately directed beams for the high points which are too dimly lighted by ordinary flood lamps. Where construction is proceeding at night and distances or heights are beyond the reach of smaller reflectors, these searchlights, ranging from a few hundred thousand up to ten or eleven million candle power, are playing their parts.

The new type of searchlight is the natural outgrowth of the lamp which succeeded, in the parlor stereopticon, the sputtering arc which did such doubtful service in the hands of amateurs. That stereopticon incandescent was such a marked improvement in steadiness, simplicity and economy over the arc that it was developed into proper sizes for small and medium moving picture projectors. The next step into the searchlight field was certainly a logical one.

Certain illuminating engineers who made the searchlight of both arc and incandescent types what it is today, labored long before they found the best method of shaping and mounting filaments so as to secure concentration of the light source in the incandescent lamp sufficient to produce a strong beam. Tungsten wire of various diameters wound into helical loops was tried in long coils and short—and even in a conical shape—but exhaustive tests showed that three types were superior to all others.

In a 115-volt, 1,000 or 1,500-watt lamp capable of producing from one to two million candle power in the beam, six perpendicular coils of filament are mounted in the formation of the letter C, the convex side of this arrangement being presented to the mirror.

The other two secure greater concentration for longer throws by operating at far lower voltages with corresponding higher currents. A 32-volt, 1,000-watt lamp good for about four million candle power has four perpendicular coils mounted at the corners of a close square. The third and most powerful of all is a 12-volt lamp of 100 amperes capable of developing as high as twelve million candle power in a beam of 3

## Guiding Ships by Electric Cables

**By M. Tevis**

DURING the war, while Germany held possession of Heligoland, the waters surrounding that famous island were, of course, densely sown with mines. Furthermore, in that vicinity dense fogs are very common, while, too, the mouths of the Elbe, the Weser and the Jahde are marked by violent currents and very high tides which make this part of the North Sea particularly difficult to navigate.

German ingenuity set itself to work to find some safe method of entering in and out of port during those hours when the fog covered them and protected them from the British lookouts. They did hit upon such a method and some time afterward it was discovered and utilized by the British, which enabled their navy to navigate without too much danger among the mine fields about Heligoland. A description of the process employed has lately been made public by Sir Arthur Evans, President of the British Association for the Advancement of Science.

To begin with, electric circulating cables carefully protected by metal coverings against fraying at the bottom were fastened to the ground at one end near a station possessing powerful alternators for sending alternating currents. All of the ships were provided with precision instruments which by induction were influenced by these currents in proportion as they approached the vicinity of the cable or, more exactly, when they came above the cable, at which moment the records of the registering apparatus grew fainter or slightly changed direction before reaching a maximum once more.

Some of these one-direction cables were as much as 90 kilometers long, and Sir Arthur Evans declared with enthusiasm that the captains of vessels became able to follow the cable at any speed whatever as easily as the street car follows its rails. It is obvious that this ingenious device is destined to give tremendous service in time of peace, as well as in time of war, especially in ports where the channels of approach are devious and difficult to follow and where there is much fog, both conditions being considerably prevalent along the English coast. From the moment a ship "picks up" the outer end of the cable, the man at the wheel need no longer be troubled by reefs, shallows and currents or even by fog.

Two cables have already

# Who Invented It First?

## Some of the Knotty Points That Come Before the Examiners in Interference

By John Boyle, Jr.

SOME one has said that there are three critical periods in a man's life: when he marries, when he starts to build his own home, and when he begins to raise chickens. To these might well have been added a fourth: when he begins to invent. There is no general appreciation of the number of people in this country who show a disposition to invent. The reports of government officials show that more than 70,000 applications for patents were filed in this country last year, representing substantially as many American inventors. There are over 600,000 unexpired patents which represent conservatively half a million living American inventors. It would not be an exaggeration to say that there are probably one million present, past, and prospective inventors alive in this country today.

With so many individuals interested in the subject of inventions it is not at all surprising that there should be times when their paths cross and conflicts arise as to the origin of some specific invention. Whenever the attention of the public is focused on some great undertaking, individuals in all parts of the world begin to devote their attention to the solution of the pressing problem. During the war when the submarine activity was at its height, the British Government received, in a few months, not far from 40,000 suggestions of ways and means to curb this menace; the number of suggestions received by our Navy Department far exceeded this. After the Iroquois Theater fire in Chicago some years ago, all kinds of protective schemes found their way into the Patent Office. The same thing happens after every big train wreck, or any other calamity the news of which is spread nationwide. A multitude of applications for patents were filed after the announcement of the sale of a concrete fence-post invention for a quarter of a million dollars; and also after the publication of the sale of the patent rights of the autographic kodak invention for a large sum. And it is entirely obvious that when a lot of people—scores or hundreds or thousands, as the case may be— get to work on the same problem, a lot of them are going to produce solutions which to all intents and purposes are identical.

Whenever two or more applicants come into the Patent Office claiming a patent for substantially the same invention, some method must obviously be devised in order to determine to whom the patent shall be granted. Only one valid patent can be granted for an invention, and under the law it must be granted to the original and first inventor thereof provided he has been diligent in reducing his invention to practice either by the construction of an actual working model or the filing of an allowable application. The question therefore to be determined is, which one meets these requirements. The proceeding which is instituted for this purpose is technically known as an interference proceeding. Every year nearly a thousand of these contests are instituted of which about one-third come to a final decision. There are two important facts in the development of an invention which it is necessary to understand in reaching a decision as to who is the prior inventor and hence entitled to the patent. One is known as conception of the invention and the other as reduction to practice of the invention.

Whenever a person begins to invent, the first step is in appreciating the desirability of doing something in order to fill a certain want. There then comes to the mind of the inventor some specific means for accomplishing the desired result. Ultimately he is able to make a sketch or a model or a working drawing thereof. When he has proceeded thus far he is said to have a complete conception of the invention. In other words, he has in his mind a definite scheme as to how he intends to construct his machine for accomplishing the desired purpose. He is not considered to have invented anything until he has reached this stage in the perfection of his ideas.

In order to perfect the inchoate right which the inventor has acquired through the conception of the invention he must now proceed to demonstrate the practicability of his device for the purpose for which it was intended. The fact that an inventor has made a drawing of his invention is not always conclusive that it will do all that it is intended to do. This can be demonstrated by subjecting it to an actual test under the conditions that would exist in practice; or as a substitute for this test, the inventor can perfect his inchoate right by filing an application for patent. This is designated in the law of patents as a constructive reduction of the invention to practice.

The pervading idea in the whole system of our patent laws is to benefit the public. As a reward for conferring this benefit on the public the law gives the inventor an exclusive right to make, use and sell his invention for a term of 17 years. This right will not be conferred if there is any doubt as to whether the invention will do all that is claimed for it. Hence the requirement as to reduction to practice.

Several different sets of conditions arise in these contests between rival claimants for a patent for the same invention. The most common is that between independent inventors; let us take such a case and see by what rules it would be decided. John Doe, a professor of physics at Harvard, wishing to contribute his little bit to winning the war, begins to devote his attention to finding a device that will detect and locate an enemy submarine. After much speculating and planning, in December, 1916, he has such a definite notion of an apparatus that will do this that he is able to make a drawing of it in complete detail. He takes this drawing around to one of his fellow professors and explains to him his whole scheme and is greatly encouraged by the favorable comment. Thereupon he begins to wonder how he is going to test out his device and demonstrate with certainty that it will do all that he expects it to do. While still considering this phase of the problem and before taking any definite steps to this end he hears that considerable trouble is being experienced by the allies in finding an effective gas mask. He thereupon lays aside his submarine detector and takes up the problem of inventing a successful gas mask, prosecutes the investigation with vigor, and by July, 1917, he has developed a gas mask that meets with the approval of the military experts. Stimulated by the success he has won in this field, he returns with renewed effort to his submarine detector. In September, 1917, he sends the drawings of this to his attorneys for an investigation of its patentability. The report is a favorable one and on October 1, 1917, he files an application for patent.

The scene now shifts. Comes Richard Roe, professor of physics in the University of California. Embued by the same spirit of patriotism as John Doe, he too begins to experiment with submarine detectors. He has reached such a point in his investigations by February 22, 1917, that he is able to make a drawing of his device, which he immediately sends to the Navy Department. Favorably impressed with the apparent utility of the detector, the Secretary of the Navy wires him to report at once to the Mare Island Navy Yard in order to have his detector tested. At a test carried on under the supervision of the yard officers he is able to detect the direction and distance of a submarine within a radius of twenty miles. On December 20, 1918, he files an application for patent.

Now the officials of the Patent Office had decided only a few days previously that John Doe was entitled to a patent for his submarine detector. But Richard Roe's detector is a Chinese copy of John Doe's. To whom shall the patent be granted? To Richard Roe, even though he was the last one to think of the device, the last one to make the drawing, and the last one to file an application for patent! But he has this all powerful fact in his favor: he was the first to reduce his invention to practical form, the first to go from the depths of probability to the field of certainty. His device will do all that is claimed for it because it has done it. If he were to die the day after the test he would have left behind him for the benefit of the public a definite and certain addition to the sum of human knowledge. His ideas would not have been clothed in speculation and uncertainty.

Now in all fairness it would seem that if John Doe was the first one to think of the submarine detector he ought to be prior in right to Richard Roe. And so the law does say and do, but with a snapper proviso on it. The reason that John Doe lost his right to a patent was because after he had conceived the invention he temporarily abandoned the idea to work on the gas mask. During the period that he had laid aside his invention, Richard Roe, unaware of the prior activities of John Doe, entered the field, conceived and reduced to practical form his own detector.

The hard lesson that John Doe has learned should be a warning to all inventors. If you are an inventor and have a definite conception of your invention, either hasten it to completion and actual test or file an application for it in the Patent Office. The first course is the preferable one, but if that is impossible then the second course should be followed. The law says that you must be diligent in reducing your invention to practical form otherwise you take the chance of some more diligent rival cutting the ground out from under you.

It may not be an inopportune time now to issue an additional warning to inventors. From a patent standpoint nothing is quite so fatal to an invention or discovery as secrecy. Of course if an inventor prefers to manufacture by a secret process and is certain that he can keep it secret, there is no objection to such a procedure. The inventor and manufacturer of a leading photographic paper has done this to his great financial benefit. But the situation under consideration here is where two or more inventors are seeking a patent for the same invention. The one will secure the patent who is able to prove the earliest acts of invention, that is to say, the date and character of his conception and also of his reduction to practice. Now if he has kept in his own heart all that he has done along this line he will have no evidence in the eyes of the law wherewith to prove that he has done what he claims to have done. It behooves every inventor, therefore, to keep some individuals—who are competent to understand and to testify to those facts if necessary—informed of all that he is doing in the line of inventing. Unless it is a very simple device it will not avail much to disclose it merely to your wife or your mother-in-law. Being interested parties, too, their testimony is not entitled to much weight.

The fear of having an invention stolen is something that seems to obsess many inventors and is probably the reason that impels them to secrecy. There were probably more Liberty bonds stolen on any day last week from reasonably secure places of deposit than of attempted steals of inventions in the whole history of the Patent Office. The inchoate right to a patent has been threatened oftener by the veil of secrecy than by the crime of thievery.

One of the most interesting and leading cases of the penalty of suppression and concealing an invention was decided in 1902. An inventor, Mason, conceived the idea of a certain kind of gun-clip, had it made and applied it to a completely finished gun. The invention was a simple device and complete in all its details. It was put away in the model room of the company which employed Mason and was entitled to the benefits of his inventions. No clips of this kind were put on the market and the gun and clip were never exhibited to the public. Seven years after the completion of the invention another inventor by the name of Hepburn, unaware of the activities of Mason, filed an application

(*Continued on page 138*)

*THE troubles of the inventor in interesting capital and getting his invention developed are an old story. Perhaps a little less familiar are some of his troubles in getting his invention past the gentlemen in the Patent Office whose duty it is to discover whether the alleged features of novelty are really new or not. It is obvious enough that if we reinvent independently and unknowingly something that has already been invented and patented, we can't expect the Government to give us a patent on it in return for "disclosing" it. What is not quite so plain, however, is that even in the absence of a prior issued patent we may have nothing that is entitled to consideration as new. How the patent examiners decide between the claims of two men who come before them with substantially the same invention, and how these men can best protect themselves in advance against an adverse outcome in such a case, are the things that Mr. Boyle tells us in this article.*—THE EDITOR.

# The Metric System

## Why We Should Measure in Meters, Grams and Liters, without Reservations

By Herbert T. Wade

THE growing and active interest in the serious discussion of the necessity of adopting the metric system in the United States has been reflected recently in the correspondence columns of the SCIENTIFIC AMERICAN. This paper for many years has believed that the adoption of the metric system, logical in its development and international in its application, would accomplish as much for manufacturing and other industries, commerce and the ordinary transactions of life in the United States as it has done in continental Europe and also in purely scientific work where its use is now universal.

It is always difficult to convince the general public of the desirability or even necessity for changes in weights and measures, and it is the experience of history that such reforms as well as those of the currency and coinage always must originate with a few enlightened and far-seeing persons and be forced upon an indifferent or hostile public. Even in matters of such vital importance as fraudulent weights and measures, false statements of quantities and similar matters, there rarely is evident any general demand either for legislation or for the enforcement of statutes bearing on this subject, and what has been accomplished has been done through the interest of a few rather than in response to the demands of the many.

### Again the Apathetic Public

Accordingly, while the matter of weights and measures both ultimately and directly concerns the general public and it is widely realized that American and British weights and measures are dissimilar, illogical and inefficient, yet it must be admitted that today there is voiced in neither country any widespread and compelling demand for changes and improvement. But as always there are now scientific and public-spirited citizens advocating reforms which are as vigorously opposed by others. As a result the people of the United States have been treated to an almost endless discussion and argument by two hostile camps composed of enthusiasts, propagandists and controversialists, comparatively few in numbers, with whom the calm consideration of facts in the light of experience, the analysis of conditions and underlying theory, and the technical, economic and logical development of the question too often have been conspicuously absent.

With the great mass of the people indifferent to metrological reforms it is all the more the duty of thinking men and women to examine the arguments and conclusions developed by those who have given study to the matter, and most of all the underlying facts, record and experience. As a consequence they will be forced to espouse one of the three following propositions: First, that there are no reforms necessary in the American and British weights and measures; second, that the existing American and British systems of weights and measures, with their duodecimal and binary system of subdivision, can be simplified, harmonized and referred to common standards with more or less modification to a decimal basis; third, that the international metric system, now in universal use throughout the world for all scientific measurements and in commerce and industry in the majority of civilized countries should be employed universally and by statute in America and Britain.

### Why the Metric System?

For each of these points of view arguments can be and are advanced, but, in our opinion, experience and logic are overwhelmingly in favor of the adoption of the international metric system, and especially if it can be carried forward on a sane and progressive basis, with due regard to the interests of all.

And this in no way contemplates the impossible or impractical. No one proposes arbitrarily and immediately to change to a metric basis such standards as railway track gage, airbrake hose, couplings or other railway fittings. But it does mean that for new types of material and new types of construction not only metric but international and universal standards should be used.

Decimal coinage has demonstrated its supremacy throughout the world, and so far as calculation and reckoning are concerned, there is no more reason for the survival of the Anglo-Saxon weights and measures as a system than for the system of currency based on pounds, shillings and pence, which progressive thought in England desires to change. It requires only a recollection of school day arithmetic to recall complicated tables with many and unnecessary units used only by those directly concerned with a special trade or calling, and the inevitable question comes, Why is the capacity measure for a liquid different from that for a dry material, or why is a bushel different in different parts of the United States? Furthermore there is not today harmony in the weights and measures of the two great English-speaking countries either in systems or standards; tons, gallons, bushels and other units are absolutely different. Though the yard, foot and inch are the same in both, yet, as a matter of fact, they now are ultimately referred to the standard prototype meter for their precise definition.

### Argument Based on Conservatism

While some favor a binary or duodecimal system from a spirit of conservatism and for alleged facility in construction, especially in hand work with dividing or foot rule, yet in actual practice these points of superiority rarely appear, at least as important elements. Of course, on the Anglo-Saxon systems of the two great nations have been built many machines, and engineering and other information have been compiled either in an extensive literature, or in valuable tables, which with any change would be rendered obsolete or require transformation. However, so far as material things go, much here is obsolete or obsolescent, change or no change, and if what is to come in design or construction or a literature or tables can be devised on a new improved and universal system, inconvenience and incidental loss would be far less than feared.

A partial change would cause practically as much inconvenience and trouble as the adoption of a new system, and the only elements that would be maintained would be the linear units and standards, with perhaps the avoirdupois pound and even for them a new and decimal subdivision is proposed. With the difference between the American and British ton, the American and British gallon, the American and British bushel, there would be important adjustments necessary in at least one of the two countries that stand pre-eminent in the world's trade, while so far as linear measurements are concerned, and here the large machine tool and manufacturing industries are concerned, any modification or readjustment of the Anglo-Saxon measures would lead to almost as much confusion as an entirely new system.

### How to Save Clerical Work

Advocating the international metric system, therefore, it is not necessary to advance the familiar arguments, many of which are sound, but to suggest a point of view that we think has been to a large extent overlooked. In modern American manufacturing cost analysis and accounting has become as general as it is necessary, and this involves considerable clerical work and calculation. Even today the metric system could be introduced into much industrial work with small expense in the way of providing suitable weights, measures, scales and weighing machines, and in the control of processes the data at any stage would be secured and handled with much less effort and clerical labor. Just as a decimal hour is used in many establishments, beginning with the raw material it would be possible to employ metric weights and measures in every stage until the final product with a considerable saving and increased efficiency. In an establishment we have in mind, a practical industrial engineer informed in weighing and measuring methods, both scientific and practical, estimated that a saving in clerical labor representing between five and ten thousand dollars per annum would be secured by recording all weights and measures in the metric system, eliminating the inconvenient avoirdupois and troy systems, both of which were used in this special plant.

There are certain industries or certain departments of large industries, where such an experiment of introducing the metric system exclusively could be carried on for one or more years with every prospect of material advantage; and it is to be urged that this be done under enlightened and scientific direction by such corporations, and that the results be described to some convention of mechanical or industrial engineers. Such work on a partial scale is done in some mechanical and electrical manufacturing plants in the United States and in a few concerns working from European plans or European orders, without, so far as can be learned, the slightest embarrassment or difficulty, but it is urged that this method be tried as an efficiency measure and the experiment should be well worth the effort. Indeed to many engineers who have given thought to the matter the practical efficiency of the use of international metric weights and measures is a single argument sufficient to warrant its adoption.

### The Serious Matter of Screw Threads

In manufacturing the mere branding of a product with its metric equivalent is a simple step, which will prove at once advantageous to foreign trade and one that can be recommended as distinctly worthy of adoption. The crux of the situation in the United States as regards the adoption of the metric system confessedly lies in the enormous and efficient machine tool industry, where standards have been followed both of individual manufacturing concerns and those conforming in general to accepted practice and based on the Anglo-Saxon system of units. In these the matter of screw threads plays an important part, and an American system has been evolved, while abroad is found a British standard system, and also one based on the metric system in less common use, known as the International System. Commissions are now concerned with the study of the American and British screw-thread systems, and of international standards in general, and it would seem to be a proper time to take action to secure an international standard which in future construction could be used. It would be desirable to have such a system based on the metric system rather than on the American or British system exclusively, and it might be suggested as worthy of the attention of an International Engineering Commission or Congress to evolve satisfactory and efficient systems of screw threads that could be used in future construction for articles designed for international commerce, and particularly for new types of machines whose construction is about to commence. Mechanical engineers in all countries must realize that production must be carried on with a view to the markets of the world, and that international standards must prevail if any individual country hopes to secure its proper place in the world's markets. The time has passed when a single nation can impress itself and its products by force on any other nation and compel acceptance of ideas and articles, and international weights and measures are distinctly in line with the progress and enlightenment of the times.

## Mechanical Bond in Reinforced Concrete

MUCH ingenuity has been displayed by inventors in the production of patented bars and other forms of reinforcement for concrete, generally, but not invariably, with the object of providing a mechanical bond to supplement the grip or adhesion between the concrete and the steel, says a British writer. As remarked by Professor Turneaure, "America is the home of the patent bar," for European engineers generally agree that the natural adhesion bond between concrete and embedded steel bars is quite sufficient to comply with essential conditions. Nevertheless, it may be at once admitted that a supplementary bond is worth securing, if the form of the bar is one not likely to cause undue strain in the concrete and if the cost of patent bars is not too high.

Many forms of patent bar are made with swellings and other projections which tend to split or shear the concrete, if the bond stress exceeds the usual working limit, and all forms of such bars cost considerably more than plain bars. So far as concerns safety from excessive strain, a good form of patent bar is one giving a continuous mechanical bond furnished by a helical surface formed by twisting bars of square or special section either after or during the process of rolling. If the operation of twisting is performed with due care after rolling the yield point and ultimate strength of the metal are raised to an important extent, while at the same time the bars are not subject to the small amount of permanent set which occurs in plain bars after being loaded for the first time. Therefore, twisted bars may provide a higher factor of safety as well as a continuous mechanical bond. In the case of bars twisted during the process of rolling the physical properties of the steel remain unchanged, but this method of treatment should lead to the production of mechanical bond bars at minimum cost.

# Our Deep-Sea Freighters

## Something of Permanent Advantage that We Got from Our Participation in the War

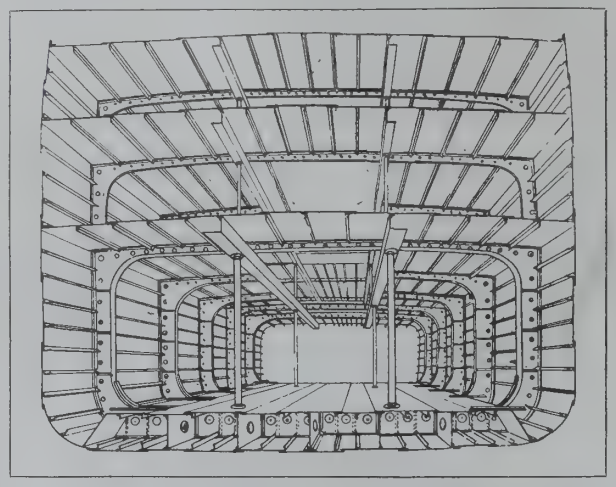
By Robert G. Skerrett

THE test of time is going to tell in our favor and bring out the fact that we fought in the World War to our lasting advantage, and this, in a sense, apart from the immediate consequences of our participation in that conflict. That is to say, the urge of strife spurred us on to achievement in one direction or another where we might otherwise have hesitated for years.

This is undoubtedly true in regard to our sudden and spectacular creation of a really formidable array of deep-sea shipping. Our newly revived merchant marine will be a worth-while aftermath of the recent struggle if we prove wise enough to make the most of these craft and to profit by what we learned in bringing them into being. It is true that mere expedition of construction cost us doubly dear in many instances, but, even so, the price was not exorbitant provided we put the sound knowledge gained to good account. That is to say, pick out the types of steamers that have since revealed their merits in service and then reproduce their kind as occasion requires—sedulously avoiding, of course, the duplication of ships that have not measured up to peacetime standards.

Among the array of vessels constructed in our various yards, the public at large has heard little about two 12,000-ton freighters built at Alameda. Not only were these boats turned out in a remarkably brief time, but they represent an order of hull get-up characterized by qualities calculated to command the attention of marine architects, shipowners and the operators of oversea cargo carriers. The steamers in question are the "Invincible" and "Courageous."

These craft were of a group of single-screw steel vessels actually in hand at the California yard for the Cunard Steamship Company when we joined forces against the Central Powers. Subsequently, the "Invincible" and the "Courageous" were requisitioned by the Emergency Fleet Corporation and completed and commissioned by that organization. The keel of the "Invincible" was laid on July 4, 1918, and the boat



**Cross section of Isherwood system, showing arrangement of deep frames and deck beams**

was put overboard on August 4, following, the actual working time being 23 days and 23 hours. She had her trial trip on October 11th, and was duly delivered to the Government authorities five days later. The keel of the "Courageous" was laid on July 4th; she was launched on the 22nd of September, and on the 27th of November she made her trial run and was likewise delivered to the representatives of the Emergency Fleet Corporation. Despite the fact that these freighters were constructed very rapidly they were nevertheless subjected to exacting inspection and were given the highest classification according to Lloyd's register of shipping. This climax was in part due to the method of construction adopted, which lends itself to both quick and thorough work.

For the sake of those interested in figures, the following particulars of the two ships will probably be acceptable:

| | | |
|---|---|---|
| Length between perpendiculars | 440 feet | |
| Breadth molded | 56 feet | |
| Depth molded to upper deck | 25 feet | 6 inches |
| Depth molded to shelter deck | 38 feet | |
| Height of 'tween decks—top of beam to top of beam—at side and amidships | 9 feet | 6 inches |
| Deadweight tonnage | 12,000 | |
| Maximum mean draft | 27 feet | 7¾ inches |
| Block coefficient about | .797 | |

These vessels are built upon what is known as the Isherwood system of longitudinal framing, have straight stems and elliptical sterns, with a complete flush steel shelter deck. They also have a steel upper deck extending from bow to stern, and the living accommodations are located in three steel houses on the shelter deck.

Each ship handles its freight through five main hatches in addition to a hatch leading into the deep tank—the latter, which is abaft the engine room, is suitable for either cargo or water ballast. The double bottom which is built upon the cellular system has piping to five of the six transverse compartments which

### A River Wall in Which Wire Mesh Replaces Mortar

A TREACHEROUS southern California mountain river, the San Gabriel, subject to tremendous floods, was held in check the past winter and spring by a wall constructed without mortar or cement. Instead of the interstices being filled with such a binder, the boulders of which the protective barrier is built are firmly held intact by heavy galvanized mesh wire, as shown in the photograph. It withstood the mighty rushes of water without a sign of weakening and saved the main highway heretofore washed out annually. This highway runs parallel with the river along a mountainside and the wall stands between it and the stream. The rubble was laid in tiers or terraces about a foot and a half deep, that at the base twelve feet wide and that on top four feet. The structure is ten feet high and 600 feet long. This wall was built with prison labor by Los Angeles County at a time when cement was obtained with difficulty, and was somewhat of an experiment; but it proved cheaper and fully as staunch as flood structures of stone and cement.

**Galvanized iron mesh held this wall of boulders together, the wall, in turn, holding the San Gabriel River to its course**

The success of this novel means of protection against floods will no doubt lead to its adaptation in many places where efforts to control sudden floods have hitherto proved futile.—By *John L. Von Blon.*

### The Ready-Cut House in France

FRANCE has always been the country of the stone house—the substantial structure built by the industrious Frenchman who thinks not in terms of the immediate future or even of his lifetime, but of future generations. Of course the war has done away with thousands upon thousands of these one-time staunch stone habitations, and the devastated regions must be rebuilt in a more expeditious manner than the old one of stone and mortar with its time-consuming labor.

So the ready-cut house has made its appearance in France. This American invention—the house which can be bought in pieces, already cut to size and fit and assembled according to blue-print—is now popular in France. Our illustration shows several offerings of French manufacturers, recently exhibited in Paris. Despite the fact that these houses are being turned out in large numbers, they have an attractive appearance. They are said to sell at a remarkably reasonable price. But the fact remains that the Frenchman, once he can get back to his normal life, is going to rebuild France with stone houses which he can pass on down to his grand children, long after the wooden houses have disappeared. — By *Ralph Howard.*

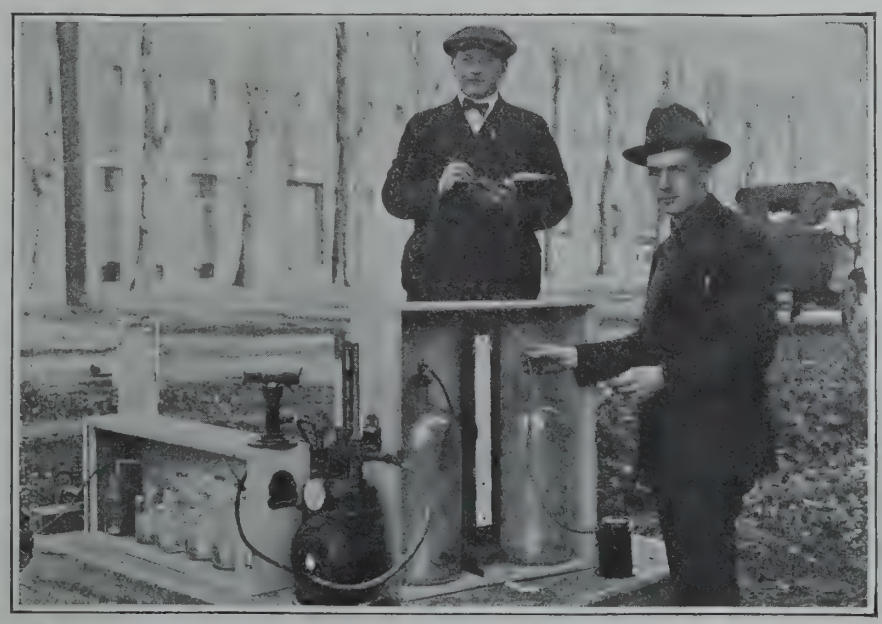
**Ready-cut houses recently exhibited in Paris and sold to the inhabitants of the devastated regions**

### Testing the Air We Breathe

IS the air you breathe pure and is the city in which you live healthy? This is an age-old query and one which often precipitates a controversy between the denizen of the valley and the man who lives on a mountain top. The former is often pitied by the mountain-dweller because of the preconceived notion that the atmosphere of the lower levels is charged with impurities; while the reply of the citizen of the valley is, "Much of your boasted ozone on the mountains is a myth."

While the U. S. Bureau of Mines would studiously avoid agitation of such a mooted question, this Government department has devised an instrument for revealing the quantity of solid matter and the gaseous impurities in the atmosphere. For instance, if there is an excess of smoke, or other extraneous material hovering over your city this apparatus would doubtless answer the question, "Is this super-abundance of smoke, say from a foundry, burdened with impurities which are detrimental to the inhabitants of the city?" The device is in practical use in Salt Lake City, Utah.

The large bottles shown in the photograph are used for detecting and measuring of sulfur dioxide, the apparatus being capable of revealing the presence of one-tenth part in one million. The weather barometer, a part of the equipment, contains a filtering thimble which ekes out the soot and other solid material. The air is measured by the meter, and then passes through the small bottles, in the left of the photograph, which containers absorb the nitrous oxide, ammonia, chlorine and other gaseous impurities. The bottle on the box, to the left, determines the amount of carbon dioxide. A motor-driven vacuum pump, situated immediately behind the boxes, forces the air through the apparatus. The job is complete—the percentage of gaseous impurities in the atmosphere is revealed.—By *S. R. Winters.*



**By means of this array of apparatus these specialists soon determine the fitness of the air which we breathe**

### Making American Roadsides Productive

BECAUSE the American roadside is an unsolved problem, and a big one, the announced intention of the highway department of an eastern State to plant fruit and nut trees along the roads, in an experimental way, challenges interest. In addition, provided the coöperation of the State Department of Agriculture can be won, alfalfa-growing enterprises will be launched. The state is New York—the highway commissioner, Frederick S. Greene.

The objects in view are several. There is the obvious one of beautification. The tree-lined highway is soothing and attractive. Second, there is the avoidance of an economic waste. The roadside land at present unproductive in the United States is enormous. Roadside weeds are a positive evil throughout the nation. The third object in view, of a different character, is understood best by highway experts. It is the protection of the built road. Trees tend to lengthen the life of a road because they shade it, and prevent rapid expansion and contraction.

It is a common practice in Europe to plant fruit trees along highways. The fame of certain districts in which cherry trees have been thus used has been spread all over the world. In the United States, aside from planting within villages and cities, the only regulated work of this character at all parallel is seen in apple-lined roads of the Northeast. When the American apple industry was a mere infant, and most orchards were a sideline on general farms, it became a common practice to plant apple trees in a single row along the walls and fences which bordered highways. These trees were inside the fence, yet they utilized the roadside in a practical manner, for half their root system, and a large part of the plant food they used, was in roadside soil. Tree-lined roads of this character are still to be found.

The road allowance generally in this country is liberal, and often manifested in excess of traffic requirements. The roadside land disused thus created may be worth as little as $5 an acre, as in some eastern rural sections which could be enumerated, or a matter of $300 or more an acre, as in some fertile farming sections of the Middle West. It may be land worthless for agriculture, or the most fertile of soils.

The New York plans are frankly tentative. They may culminate in a leasing system under which the roadside production of certain areas is let to farmers, or they may end in the conclusion that any administration of roadsides must be entirely public. It is suggested that, carefully handled, the roadsides might contribute substantially to the cost of road maintenance.

In the well-settled farming counties of the Middle and Far West, there is often a crying need for well-regulated administration of the roadsides. Especially has this been felt the past two seasons, when hay and pasturage being high in price and scarce called general attention to the resources of the highways.

In some communities, the farmers of a neighborhood would turn their stock out on the roads; the man owning the most stock derived the most good. In some other places, it was illegal to pasture stock on the highways, even in the care of a herder, and no provision for utilization of the roadsides was made.

# The America's Cup Races

## Notes on the Contests for 1920

By J. Bernard Walker

THE struggle of 1920 will go on record as the keenest in the history of the America's Cup. Perhaps this statement would be closer to the truth if the "Resolute" and "Shamrock" were being sailed boat for boat; for the races had not proceeded very far before yachting men were convinced that "Shamrock's" chances of winning the Cup, subject to the heavy burden of over seven minutes' handicap, were very slight.

Nicholson, the designer of "Shamrock," has stated that these races are practically tuning up races for "Shamrock," and it is certain that what little sailing she did against the 23-meter "Shamrock" was of little value to her; this for the reason that she so greatly surpassed the older boat on every point of sailing. "Shamrock" never had an opportunity to try herself out against a boat of her mettle until she met "Resolute." Positive proof of this is seen in the fact that she was able to beat the 23-meter boat by something like fifty seconds to the mile, going to windward, on which point of sailing if the wind holds true, she seems to be from two to three minutes in 15 miles behind the Herreshoff craft.

Weatherliness has always been a distinguishing feature of Herreshoff's designs no matter what the size or type, whether knockabouts, 30's, 50's, or 90's, or whether sloops or schooners; and it is because "Shamrock IV" was so greatly superior to the famous 23-meter boat in windward work that there seemed to be a fighting chance of her pulling out the necessary seven minutes' lead, with just a little over to score a win.

"Shamrock" foots fast enough on every point of sailing, and the fact that she is able to reach the outer mark only a minute and three-quarters behind "Resolute" in a turn to windward of ten miles, proves, to our thinking, that she must be footing faster through the water than "Resolute." Just how great is the difference in pointing, we do not know, but it must be at least a quarter of a point to put her so far to leeward on a board of any length. It is possible that Nicholson, if he had the time, could make such changes in the sailplan and in the lateral plane as would enable "Shamrock" to lie as snugly to the wind as does "Resolute"; though we are inclined to doubt it. If this could be done it is quite possible that in a series of a dozen races in winds that held true, the result might be a tie between the two boats.

Since we last went to press the "Resolute" picked up another race, thus making the series a tie. This fourth race, held over a triangular course, was sailed in a freshening breeze, the first ten miles being laid to windward. On this leg, "Resolute" pulled out a lead of one minute and forty-seven seconds. The second leg consisted of ten miles of broad reaching, and had the wind held true, there would have been another ten miles on a broad reach to the finish. Since this was generally considered to be "Shamrock's" best point of sailing, it was thought that she might save from four to five minutes of her allowance. But to the surprise of everybody on board the yachts which followed the races, her gain in ten miles was only forty-three seconds. In view of the fact, however, that this leg was sailed at a speed of slightly over twelve knots, the gain of three-quarters of a minute was very creditable. Three-quarters of a minute gain at that speed would, of course, be considerably greater if the course were covered in light winds that would require the whole six hours to complete the course.

On the final leg, "Shamrock" continued to gain and seemed to have pretty well made up the remaining minute that "Resolute" had gained to windward. She was so close that "Resolute" had to luff out to prevent her passing. At this time the meteorological conditions were most unusual. A white fog bank was moving up against the wind to meet the yachts, and a black squall seemed to be about to burst upon them from to windward. The skipper of "Shamrock," realizing that there was no chance of picking up his seven minutes of handicap, determined to play safe and took in his club topsail. "Resolute," however, held to hers, and as the black squall failed to materialize and the boats ran into a comparative calm, "Resolute" was to the good as regards canvas for the rest of the race. After the wind had headed both yachts, it finally settled down to a quarter which enabled "Resolute" to come home with her balloon jib carrying a good rap full. She gained on the last few miles of this leg two minutes and fourteen seconds, winning the race by three minutes and eighteen seconds, or nine minutes and fifty eight seconds, corrected time.

" Shamrock IV " leads " Resolute " across the line in a dead heat; but " Resolute " wins by her 7 minutes 1 second time allowance

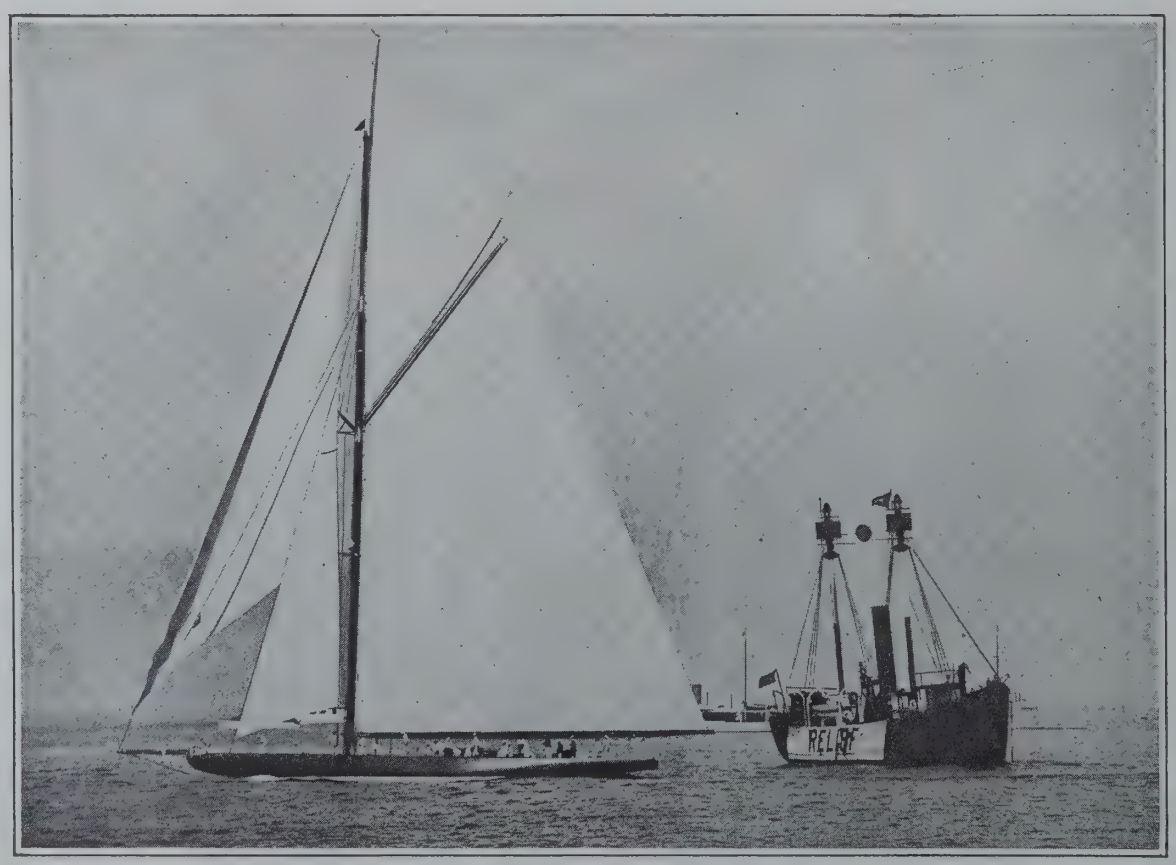
**Finish of third race—30 miles windward and leeward**

The two boats were now tied with two races for each. The earlier attempts to pull off the deciding race were disappointing to the point of exasperation. On Saturday, July 24th, there was a splendid breeze of from 22 to 28 knots' force, but unfortunately, it was accompanied by a short and rather heavy sea caused by the wind meeting the tide. Both boats labored so heavily when reaching over the few miles from Sandy Hook to the Lightship that by mutual agreement of the skippers and the Race Committee the race was postponed.

The incident is a significant commentary upon the unseaworthiness of these modern racing craft, whose scantling has been skinned down to the last ounce of weight, and whose towering rig, with its hollow spars and attenuated standing gear is poorly constituted to stand the dynamic forces which result from a squally wind and a short, snappy sea. As Sir Thomas Lipton's steam yacht, with guests aboard, steamed back inside the Hook to speak to "Shamrock IV," she passed the 23-meter "Shamrock." "There," said one of the guests, a grizzled yachtsman who has been in the game for over thirty years, "there's a boat that would have fairly reveled in such a day as this." But the 23-meter "Shamrock," as we have already recorded in this journal, was built under a rule which seeks to combine the fast racer with the comfortable cruiser. Her scantling and masting had to be built to strict specifications, and more than that, before she could enter the races she had to be given an A1 classification by Lloyd's, based upon these specifications.

Yachting nations of all the world, realizing the then existing conditions tended to produce such boats as "Resolute" and "Shamrock," recently got together and drew up a rule which is a modification of the rule under which "Shamrock" was built. An earnest invitation was sent to the United States, asking us to join in this movement, and Mr. Burton, who sailed "Shamrock IV," came to this country to further the request. But unfortunately, as we think, the representatives of our leading yacht club refused to enter into any such association. Had we done so, any yacht of any nation would be eligible to enter the local regattas

(Continued on page 140)



" Shamrock IV " passing the Ambrose lightship, with a lead over " Resolute " of 9 minutes 27 seconds actual, and 2 minutes 26 seconds corrected time

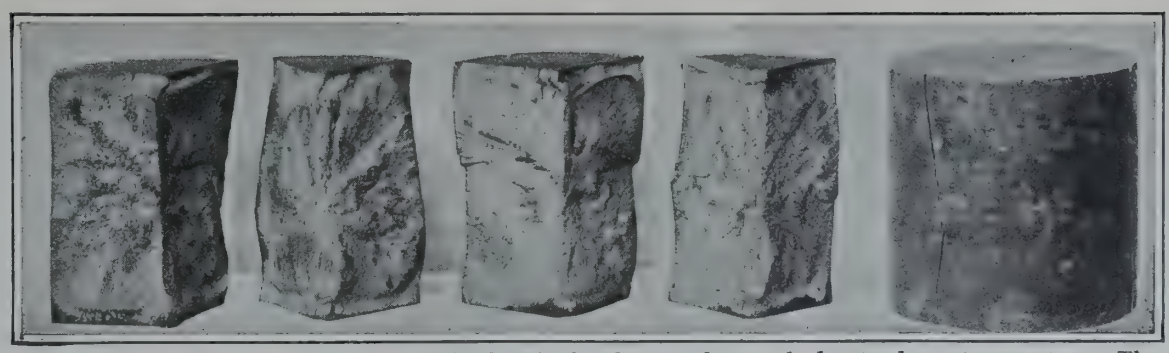
**Finish of second race—30 miles triangular**

## When Steel Explodes—and Why

WHO ever heard of a chunk of steel exploding? None of the metallurgists in the General Electric Research Laboratory ever had until one May day this year. On that day Herman Winkler, an employe busy hardening three slugs of ordinary Sanderson carbon steel to be used as plungers in making genelite, a new self-lubricating bearing metal, drew a slug out of the electric furnace at about 750 degrees Centigrade, quenched it in a tank and then took it in his left hand. With a rasp in his right hand he was about to test the slug's hardness when someone distracted his attention. In that moment the end of his rasp tapped the flat end of the slug.

"It flew to pieces with a crack like a pistol shot," said Mr. Winkler. "One chunk went by my ear, another went straight up and the remaining two dropped into the sink. It was peculiar. My hand was merely bruised a little bit."

The only explanation advanced for the phenomenon is that the slug, which was about four and a half inches long and four in diameter, cooled a degree too quickly on the outside and the heat-expanded core exerted a surface tension so unusual that the slightest touch at that exact moment produced the violent fracture. The other two slugs from the same bar that day got what appeared to be exactly the same treatment, as have thousands of other steel slugs in times past, and not one ever responded as this one did. The photographs show there was no flaw in the metal, but the lines of core strain are obvious.



**The first four fragments show the explosive break of carbon steel, quenched to too low a temperature. The fifth specimen shows carbon steel block broken by hardening strains**

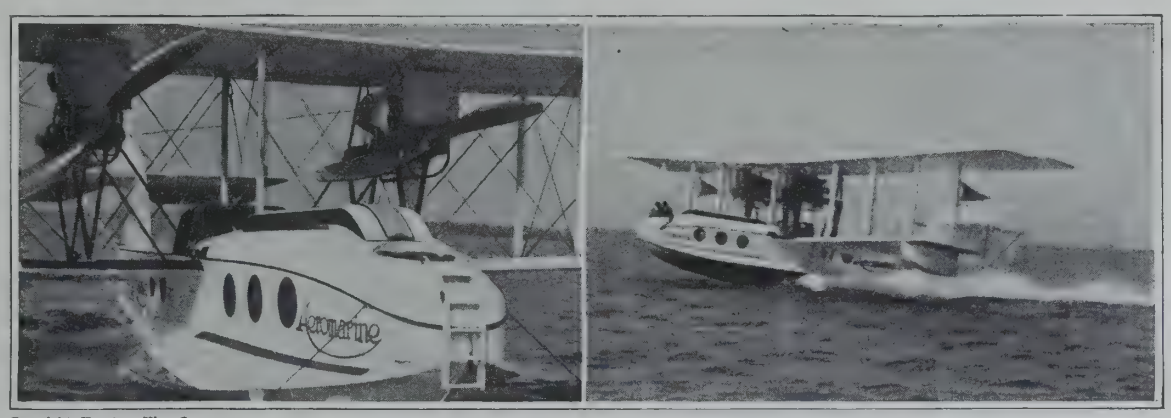
## Our Latest Aerial Creations

WHATEVER may be said regarding the dumping of foreign airplanes in these United States, the fact remains that we are pretty well able to take care of our aerial needs both as regards quality and quantity. In fact all that seems necessary just now is for the Government or the public at large to give the aircraft constructors proper support in order that they may hold their equipment and personnel intact.

Two of our recent aerial creations are the huge L.W.F. plane and the sturdy Aeromarine cruiser, both of which are shown in the accompanying illustrations. These large aircraft compare most favorably with those of England and France, and are only surpassed by the all-metal giants of Germany. For that matter Germany—and we have reiterated this statement over and over again in these columns in the spirit of scientific impartiality—has a monopoly in all-metal construction for some reason which is hard to fathom.

The L.W.F. giant can be briefly described as a biplane with two fuselages and a central nacelle, driven by three Liberty engines with tractor screws. The wing spread is 105 feet. The machine has been purchased by the U. S. Army for use as a bomber.

The Aeromarine cruiser is designed to carry fourteen persons. It has a wing spread of 103 feet, weighs eight tons, and is driven by two 400-horse-power Liberty engines. The main cabin accommodates nine, while the smoking compartment seats five. The equipment, which is quite complete, includes a buffet.



Copyright, Keystone View Co.

## Observations on Radio Transmission Phenomena

THE Bureau of Standards has secured the coöperation of the American Radio Relay League in the collection of data for a study of the nature and causes of the fading of radio signals. It has been observed by radio amateurs generally that the strength of signals received from a given transmitting station varies rapidly during very short intervals of time, this variation probably depending upon the weather and various meteorological conditions.

In order to secure simultaneous observation of signals, arrangements have been made for a number of well equipped amateur radio stations, including six transmitting stations and about forty receiving stations, to begin such a series of tests. The six transmitting stations will send out a broadcast message lasting about three minutes each on Tuesday, Thursday and Saturday evening, beginning just after the time signals from the Arlington Radio Station of the Navy. These stations will transmit for their different regions ten minutes apart, and three or four of them will be within the receiving range of each receiving station.

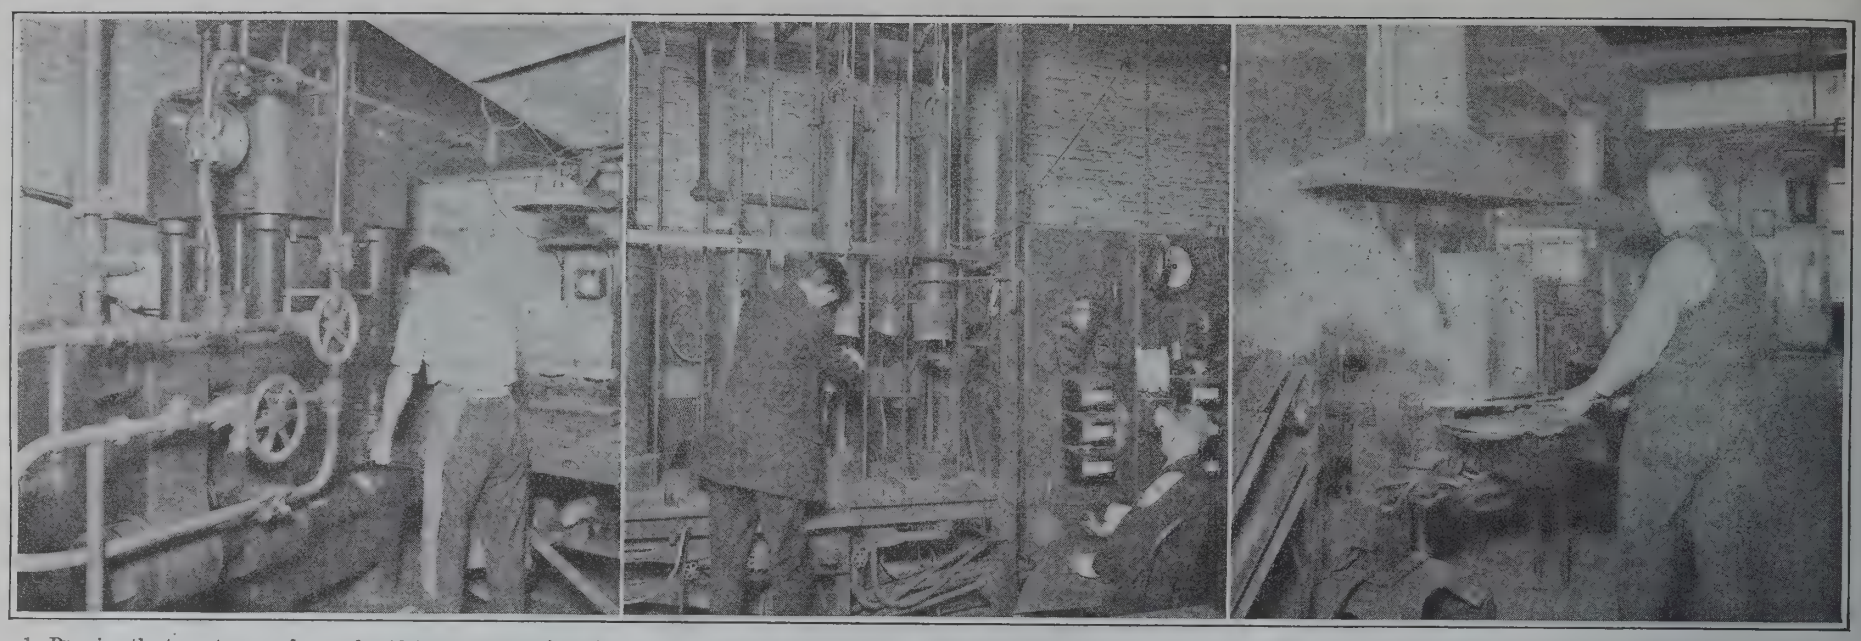
Forms have been provided by the Bureau of Standards on which the operators will record the strength of the signals which they receive, weather conditions, presence of strays or atmospheric disturbances and the general character of radio transmission at the time of each observation.

It is hoped that from this program of careful observations some valuable conclusions regarding radio transmission will be worked out. If the present plan, covering only the northeast part of the United States is successful, a more extensive program may be undertaken during the coming winter.

## Mental Tests in Schools

THE National Research Council announces that the mental tests which were used with striking success in the Army during the war are to be used on a large scale in American public schools. A program of group tests has been worked out which will make it possible to conduct wholesale surveys of schools annually, or even semi-annually, so that grade classification and individual educational treatment can be adjusted with desirable frequency. Prof. R. M. Yerkes is in charge of this undertaking, and the General Education Board is furnishing financial support.

**Two views of the giant L. W. F. biplane, which has a wing spread of 105 feet and which is powered with three Liberty engines**



1. Pressing the tungsten powder, under 16 tons pressure, into blocks that are too crumbly to handle. 2. # The Romance of Tungsten

## How This Erstwhile Brittle Metal Was Made Available for Lamps

By George Gaulois

A CASUAL look at the filament of the incandescent lamp in your library or at the tiny spark coil contacts on your automobile brings no suggestion of the romance of science which lies back of those devices. It is the romance of tungsten, one of the heaviest of metals, a metal nearly 140 years old but which resisted the efforts of mankind to make use of it in its pure state for about 130 years.

Yet the service pure tungsten has rendered the world in the last decade since it was "conquered" is almost too great for calculation. Tungsten in its various forms reduced America's electric light bill a billion dollars a year and more than doubled the usefulness of the incandescent lamp. Ductile tungsten kept the automobile industry alive during the war. It helped make possible the Coolidge X-ray tube with tungsten targets which tremendously increased the value of the X-ray machine to mankind. With it the pliotron was built so that wireless telephony could be developed to a useful and dependable point. With it the tungar rectifier was created so that owners of automobiles could charge their cars in their own garages by simply plugging into a light socket. With it phonograph needles are being made more than 50 times as good as the steel and the fiber needles, heretofore considered the best that could be produced.

Tunsten bullets might have served in the recent war as projectiles hard enough to pierce the heaviest armor the Germans could put on their aircraft, for a few were made to prove their usefulness in that capacity, but the plan to use them was given up after a less expensive way to accomplish the result was discovered.

Before the war only a few thousand tons of tungsten ore were mined in all the world and the price of raw tungsten ranged around 90 cents a pound; but with the war came a tremendous demand for tool steel hard enough to work at high speed though red hot. Tungsten was required as an alloy to make such steel.

*TUNGSTEN, at once the hardest and heaviest of metals, for a century after its discovery was brittle in its pure state and therefore unworkable. How Dr. Coolidge made it sufficiently ductile for the purposes of wire-drawing, and thereby lopped a billion dollars off the lighting bill of America alone, is the story which Mr. Gaulois puts before us here.*—THE EDITOR.

The price rose steeply when the supply diminished before the sudden demand until it reached $7 or $8 a pound. The world's production in 1918 amounted to 35,800 tons. The control over the sources of it was 59 per cent American and 35 per cent British. The price and production slumped with the end of the war until today raw tungsten can be bought for a little over a dollar a pound.

Most of the adaptations for tungsten are due to a discovery made by Dr. W. D. Coolidge, a physicist in the research laboratory of the General Electric Company of Schenectady. He was the first man to find a way to work this most brittle of metals. He made it ductile and thereby hangs this tale.

For about 100 years tungsten had been known before it was put to any use whatever, even as a mere alloy. Its presence was first noticed by Scheele and Bergman in 1781. They found traces of it in a metal called scheelite and coined the name "tungsten" for it from the Swedish "tung," meaning weighty and "sten" for stone. In 1783 three Spaniards discovered tungsten in the mineral wolfram. To this day there is little tungsten taken from any other minerals. It is found in small quantities in Cumberland, England; Limoges, France; and in parts of Connecticut and North Carolina, but most of it comes from Colorado and China.

Extracted from these minerals and pulverized,

(*Continued on page 140*)

**Making tungsten wire of almost invisible gage for lamps**

**With the exception of the legs and the tail, this potato was found as it is**

## When Is a Potato Worth $140?

FREAK vegetables have always been a source of much interest—and much money, too. The Chinese, for instance, pay high prices for ginseng roots which resemble the human form; indeed, these odd-shaped roots are graded according to their relative similarity, and sold to superstitious Chinese at prices ranging from very little to a good deal more than these roots can ever be worth as far as medicinal properties are concerned.

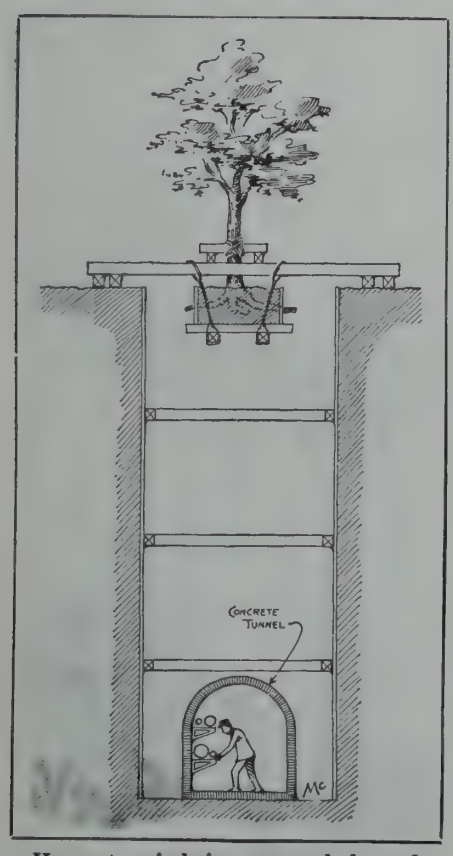
We present in the accompanying illustration a potatoe which brought $140 at a fair in Tacoma, Wash. This potatoe, with the exception of the legs and the tail, is a natural growth, yet its resemblance to a pig could not be better. It was the subject of much interest and many persons took a chance on winning it as the result of a raffle for the purpose of raising money for the boys in the army and navy.

## The Worth of a Tree

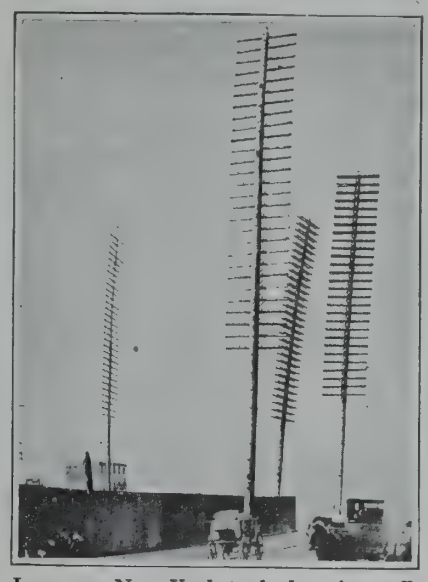
THAT the welfare of a tree is something to consider is being well illustrated on the Capitol grounds at Denver, Col. In surveying for an underground passage way to connect the State Museum with the new executive building a block distant it was found that an elm tree was in line of the proposed work.

The contractor was for cutting it down, or replanting it at least. But no, the results of replanting a tree of any size are not always satisfactory and as trees are being looked upon generally as good citizens, risks are not to be taken. So under painstaking supervision the roots were shored with long timbers, the ends of which rested on the ground at either side of the tunnel line. Under this a platform was then built, suspended basket-fashion from planks and cable spanning the space to provide adequate support.

In excavating for the passage-way a generous portion of the earth was left about the roots of the tree so as to assure their nourishment and safe-keeping. Some thirty feet below this suspended trunk the men are digging and cementing and walling the tunnel, and when it is all done the earth will be filled in underneath the platform, the timbers will be removed and life for this elm, it is hoped, will go steadily on.



**How a tree is being suspended—and saved—while a tunnel is in building**



**Long ago New York took the wires off these poles and buried them under the streets**

## New York's Buried Wires

THE accompanying view is reminiscent of the early days of the telephone in New York City. Some thirty years ago it was the practice to place telephone and telegraph wires on lofty poles and cross-arms just as is now the case in rural communities and even in large cities.

With the most commendable foresight, the telegraph and telephone interests of New York City early in their career decided to place their wires underground. For this purpose special ducts and tunnels were provided under the city streets, and the unsightly poles with their maze of wires soon became a thing of the past. Today New York is a model of neatness as regards wires. Indeed, there are practically no wires to be seen in the city proper, and it is only in the outskirts of the metropolis, where the metropolitan atmosphere is more or less lost anyway, that one comes across telegraph and telephone poles.

## Effect of Oils on Strength of Glues in Plywood

PLYWOOD may be used near machinery and tanks with little likelihood of being dangerously weakened by the action of oil or gasoline on the glue joints. This fact is evident from a test lately completed at the Forest Products Laboratory.

Plywood panels glued with animal, vegetable, blood albumin, and casein glues were immersed for nearly a year in engine oil and gasoline. At regular intervals specimens were removed from the liquids and tested for joint strength. All the glues weakened somewhat during the early part of the test, the animal and vegetable glues more than the casein and blood albumin glues. The total loss of strength in any case, however, was small enough to be negligible under most conditions of service. A glue shear strength of 100 to 125 pounds per square inch is considered sufficient for practically any purpose for which plywood is used. Only in two or three instances did the strength of the casein and blood albumin glues fall below 150 pounds per square inch. Engine oil, castor oil, and gasoline seemed to have practically the same effect on the glue joints.

## Wireless Music and News for the Roller Chair Passenger

ASBURY PARK, N. J., has the unique distinction of being the first city in which boardwalk roller chairs have been equipped with wireless telephone and telegraph receiving apparatus so that the passengers are enabled to hear talking and musical concerts from distant stations while the chair rolls merrily along.

W. Harold Warren, who some time ago demonstrated that it is possible to receive wireless telephone and telegraph signals within a steel and concrete bank vault with both inner and outer doors closed and with no external connections to the instruments, is responsible for this new innovation that has already proven so popular at this charming seaside resort.

A small flat "loop" replaces the ordinary aerial and ground connections, and the whole apparatus is so compact that three persons can sit with it comfortably in the chair. The most interesting part of the installation is the fact that the vibrations of the roller chair in motion have no effect whatever on the reception of the signals.

The directional effect of the "loop" is most pronounced, the strongest signals being received when the vertical plane of the "loop" is in the direction of the transmitting station. Signals from stations over 200 miles distant are received with the apparatus.

**These hob-nailed shoes have been worn for 90 days with hardly a sign of wear**

## Why Not Hob-Nailed Shoes?

THE Bureau of Standards has been conducting a series of interesting tests on footwear in view of the high price of shoes and leather. One particular test took the form of wearing a pair of hob-nailed shoes for several months in order to determine to just what extent the nails take up the usual wear of the leather. The pair of shoes shown in the accompanying illustration was subjected to ninety days' actual wear by means of a machine devised for such tests. As will be noted the leather is hardly worn, while the hob-nails are practically worn down.

## Using Water for Blasting Rock

A WRITER in a German technical paper describes a hydraulic device for blowing up rocks, and, in particular for demolishing bridge piles and ferro-concrete foundations. It is based on the principle of the hydraulic press; enormous pressures are set up within the rock, which eventually bursts. The pressure is transmitted by a pipe-line to a cylinder 85 millimeters in diameter in which eight pistons may be successively displaced telescopically. The cylinder is inserted into a hole, drilled by an electric drill in the rock to be blown up. The pistons bury themselves in the rock one after another and blow up the rock. The holes take 10 to 15 minutes to drill (they are about 2.5 centimeters deep), and in 5 minutes after that the rock is shattered. It is said that this device has proved successful in mines and quarries where the use of explosives would be dangerous.

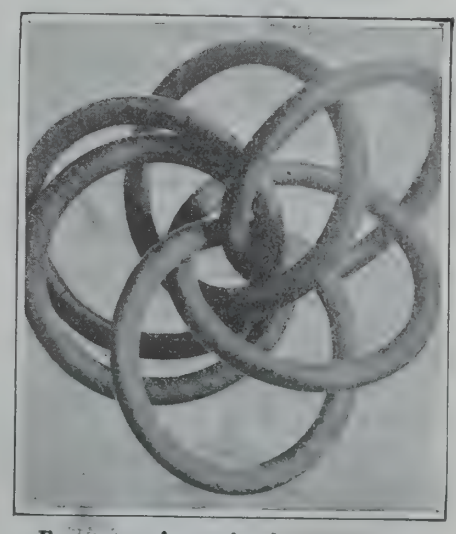
**The loop antenna enables roller chair passengers to listen to music and news reports**

## Try This Whittling Job on Your Pen-Knife

A MASTERPIECE of whittling has just been completed by A. T. Cook of Hyde Park, N. Y. The rings shown in the accompanying illustration are cut from a solid piece of wood and are said to form the most complex and difficult piece of whittling ever accomplished with a jack-knife.

But the aforementioned claim is a difficult one to defend; there have been many remarkable pieces of whittling shown and described in these columns during the seventy-five years this journal has been issued.

The rings here shown are so whittled that each one passes through all the rest, thus complicating the work of making them. Mr. Cook, so we are told, has been whittling more or less for forty years, and considers this piece of work his best achievement.



**Forty years' practice in whittling is represented in these rings cut from a single piece**

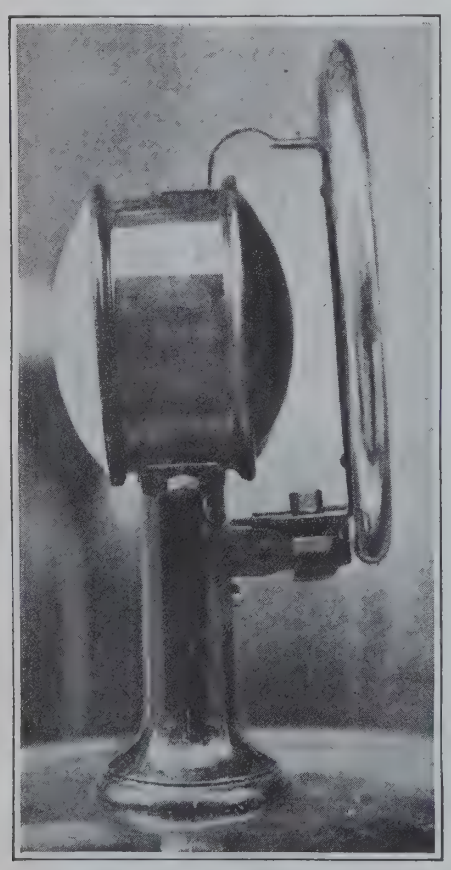
# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*

**A charge of sawdust burns twelve hours in a stove invented by an Englishman**

## A Sawdust Stove for Coal-less Europe

THE coal shortage which many of the European countries face this coming winter has not failed to spur inventors in the direction of new fuels and stoves. One of the most recent attempts to solve the heating question is presented in the accompanying illustration, and consists of a special stove which burns sawdust. The stove consists of a cylindrical casing provided with suitable holes for draft purposes, and a container which is packed with sawdust as shown. Once ignited, the tightly packed sawdust is said to burn slowly and evenly, giving considerable heat. A single charge of sawdust burns twelve hours. The action, we are told, is very much the same as coal as far as smooth burning and the intensity of heat are concerned.



**A mirror and parking light in one for the motor car**

## Difficulties of the German Paper Industry

ACCORDING to a recent issue of *Kölner Zeitung*, the German paper industry is seriously handicapped by the scarcity and increased prices of raw materials. This is particularly true of old paper and rags, which are extremely difficult to obtain, and have reached a price which appears unjustified. It is believed that old paper and rag dealers have been holding their supplies to drive prices up. The demand is very great and constantly increasing in spite of the fact that consumers believe present prices cannot continue. The cellulose plants in eastern Germany, which have been forced to suspend production for some weeks owing to the shortage of coal, have recently resumed operations, and it is hoped that renewed deliveries of cellulose will help to drive down the prices of old paper and rags. Straw, which is used in large quantities in the German paper industry, is now quoted at 55 to 60 marks per 100 kilos, but this price is expected to fall in the near future. It is hoped that this will also have an effect on the prices of other raw materials. Wages in the industry have risen over 100 per cent since December, and the cost of coal, chemicals, dyes, and other raw materials has risen in like manner. Manufacturers have therefore been forced to increase the price of paper to a point where the demand is seriously affected. Unless the cost of raw materials falls very soon the industry will undoubtedly suffer.

## A Mirror by Day—A Light by Night

IN order to comply with the laws of many States which require the car owner to equip his car with a mirror on the left front mudguard and to keep lights burning when his car is parked at night, an ingenious inventor has recently introduced a combination mirror and parking light shown in the accompanying illustration.

During daylight the mirror is held in the position shown in the illustration, always ready for use. Its position on the mudguard gives it an ideal field of vision. At night when the car is to be parked or left standing the mirror is dropped down to the horizontal position and the light is flashed on. The front lens of the lamp is white, while the rear one is red. In this manner the automobile shows a white light in front and a red light toward the rear, in compliance with the State laws. Incidentally—and this is a very powerful argument in favor of this new device—there is a saving of considerable current when operating this light in place of the usual equipment. Indeed, the inventor claims that the usual lighting—two headlights and the tail light—requires several times the current used by his device for accomplishing the same purpose.

## What Did the Dentist Put in Your Mouth?

LIKE battering the head of a rivet with constant tapping until the tiny bit of metal is flattened, similarly the point of your tooth (for instance, in chewing beefsteak) from an opposite jaw applies a load of several thousand pounds to the square inch on the amalgam or teeth fillings. The intensity of the pounding is caused by the restricted area in which the point of the tooth operates.

What is the relative wear on your teeth fillings, what is the crushing strength exerted upon amalgam, and what influence has ice water and hot foods on the artificial patchings in the cavity of your tooth? These questions are not insignificant when a visit to the dentist is convincing proof that dental material figures in the budget of H. C. L. So the U. S. Bureau of Standards devised a special apparatus for testing the wear and tear on fillings when subjected to constant pressure. Not that there should be any release of the tension placed on the amalgam in the mouth—as this would result in bad digestion—but the experiments sought to determine the durability of the material entering into the construction of teeth fillings.

It was discovered that by rapid-fire eating—when the crushing load is constant—the pressure exerted on the teeth fillings is in excess of 22,000 pounds to the square inch. This rate was indicated when the amalgam was crushed quickly, within three minutes—the dental material had set for 48 hours. However, by applying a constant impact of 3,200 pounds, one-tenth of the former crushing load, it was possible to crush some of these same amalgams in 20 hours.

With the foregoing facts established, comparative flow tests were made. Within two hours after packing, a load of 3,200 pounds to the square inch was applied to a specimen of fillings 4 millimeters in diameter and 8 millimeters long. The new type of apparatus used, specially designed for the purpose by the Bureau of Standards, consisted of a micrometer with a weight pan attached at the top of the upright rod or plunger. The two ends of the specimen of fillings were cut at right angles to the axis and inserted in the jaws of the micrometer. As the amalgam is subjected to pressure by weight applied at the top of the rod the indicator moves around the dial. The difference of readings reflects the amount of flow. An air cushion plunger in the micrometer obviates possible injury to the instrument if the fillings fracture abruptly.

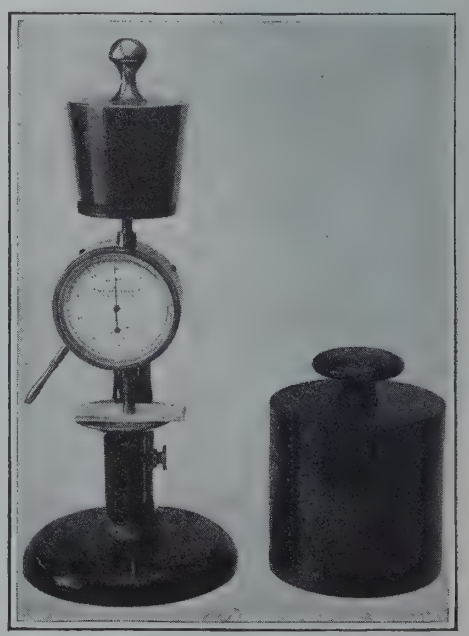
Two hours after amalgamation and packing, the specimen was subjected to a pressure of 3,200 pounds to the square inch, being compressed 4 per cent in thirty minutes. Most amalgams will withstand this test well at one hour and a few at 30 minutes after packing. It was concluded that the qualities of failure seem to be inherent in some dental material, these failures betraying their weaknesses as readily after 48 hours as after 30 minutes. The chemical composition of one's teeth fillings vary from 45 to 69 per cent silver and from 0 to 5 per cent zinc, copper and tin making up the balance.

Samples of fillings showed irregular behavior when subjected to a temperature of 80 degrees Centigrade, the conclusion being that such temperature may exercise injury to the amalgam or change its physical properties. Tests with ice water at a temperature as low as 5 degrees Centigrade and with hot foods at temperature as high as 60 degrees Centigrade indicated no excessive pain on adjoining vital teeth. Excessive percentage of copper in teeth fillings will produce discoloration.

**When the vanity bag is opened the Jack-in-the-Box shoe cleaner is ready for use**

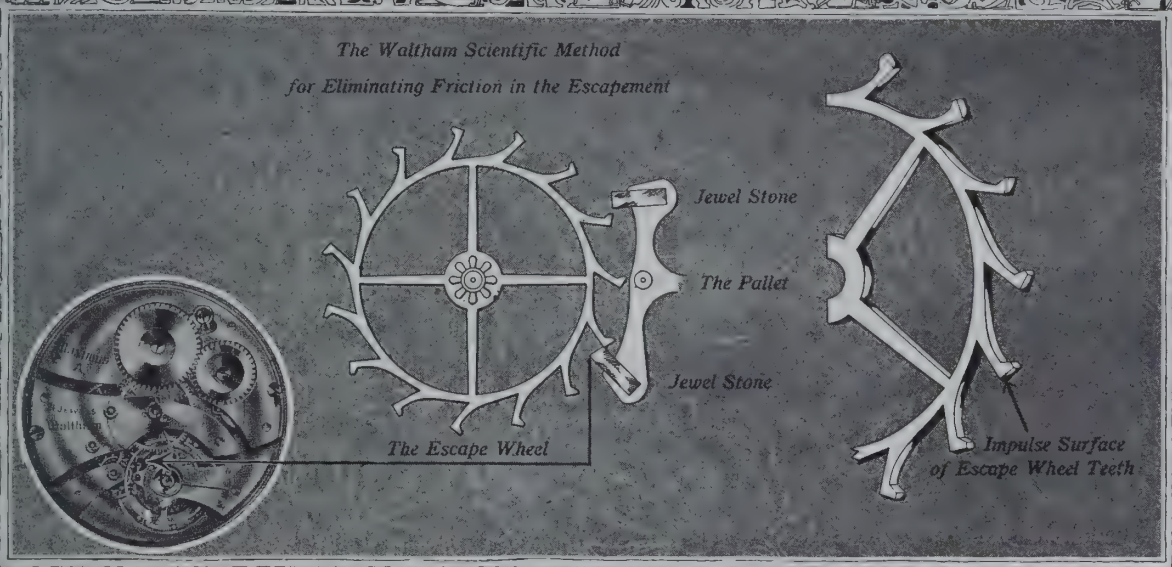
## A Jack-in-the-Box Shoe Cleaner for the Vanity Bag

THE latest addition to milady's vanity case is the Jack-in-the-Box shoe cleaner, shown in use in the accompanying illustration. A strong spring is conveniently camouflaged in the dainty vanity case or bag so that normally there is nothing to indicate that the wearer has conspired to get along without the ubiquitous shoeblack. However, upon opening the compartment containing the Jack-in-the-Box shoe cleaner, the spring jumps out with the pad at the free end. The shoe cleaner can then be used in the manner shown for dusting and cleaning the shoes, after which the spring is pushed back into the vanity bag.



**A micrometer arrangement whereby teeth fillings can be tested**

# PROOF



## THE MOST SCIENTIFICALLY BUILT WATCH IN THE WORLD

The Waltham Scientific Method for Eliminating Friction in the Escapement
Which Means Accurate Time-keeping and Dependability of Your Watch

THE pallet stones (pieces of selected Ruby or Sapphire perfectly formed in rectangular shape and highly polished) check the power which comes from the mainspring in your watch and then release it 18,000 times or beats per hour.

In these governing functions of the escape-wheel an impulse is given to the balance wheel, which is transferred in governed movement, called Time, to the hands of the watch.

Think, for a moment, of the possibility of friction, where the pallet jewels slide over the impulse surface of the escape-wheel teeth (illustrated above) 432,000 times every twenty-four hours!

Here was an opportunity for Waltham invention to minimize friction practically to the vanishing point. And friction is the most insidious and dangerous enemy to correct time-keeping in the works of a watch.

After years of experiment and development, Waltham invented a machine equipped with a diamond cutter which not only cut the diameter of the escape-wheel to its exact size, but left the impulse surface of the teeth so perfectly shaped (rounded) and highly polished that when the face of the pallet stones (jewels) slid across that surface, friction was practically reduced to its ultimate minimum.

It can readily be seen that this development of the diamond cutter has given the Waltham Watch a positive and valuable advantage in time-keeping and unvarying performance.

The ordinary method of making an escape-wheel is to polish with some polishing compound which being composed of gritty elements cannot be used without particles of grit becoming embedded in the polished surface. This in time roughens the surface of the pallet stones, eventually causing greater friction and consequent variability of time-keeping.

The Waltham Scientific Method, then, of cutting and polishing with a cutter made from a diamond is another hidden, yet vitally important, superiority in the "works" of a Waltham Watch which provides an unanswerable reason why your watch selection should be a Waltham.

## THE WORLD'S WATCH OVER TIME

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

### Pertaining to Aeronautics

DIRIGIBLE AIRSHIPS.—J. JANDA, c/o U. S. Navy Recruiting Station, Tulsa, Okla. Among the objects of the invention is to provide a dirigible airship having a plurality of independent or separable gas bags or equivalent buoyant receptacles so coupled together during normal operation as to operate as a unitary ship, but which in the event of serious damage to one of the bags it may be separated from the remaining bags, permitting the latter to continue on their course for further operation. A further object is to provide a large aircraft for the convenience of a number of aeroplanes and for the despatch of such planes from the parent ship.

PARACHUTE.—J. W. TAYLOR, 12310 Miles Ave., Cleveland, Ohio. The invention has for its object to provide a device especially adapted for supporting an illuminant packed in a suitable container, and in the form of a projectile adapted to be fired from a gun and exploded at a predetermined point, to release the illuminant and the parachute wherein the parachute is so arranged as to relieve stresses imposed thereupon in retarding the velocity of the illuminant at the high velocity at first obtaining.

### Electrical Devices

EXTENSION BASE LAMP BULB.—P. P. HEIN, c/o Bory, 444 E. 79th St., New York, N. Y. Among the objects of the invention is to provide an electric lamp bulb having an adjustable or extensible base whereby when the base is locked in the reflector socket the filament or bulb portion proper may be adjusted axially toward or from the socket anchorage for focusing purposes. The device is adapted to be fitted for use in connection with any ordinary reflector, the socket of which has a fixed position with respect to the reflector.

### Of Interest to Farmers

HAY COCKING MACHINE.—J. A. FRANCE, Sault Ste Marie, Mich. The object of the invention is to provide an arrangement of hay cocking machines wherein hay is gathered up and deposited on a platform for discharging after having been arranged in a cock of the desired size. A further object is the provision of a machine for gathering hay into hay cocks formed with the lifting mechanism having supporting ropes normally sagging between adjacent cleats for receiving the hay from a hay rake or gatherer and discharging the same at a given point.

GRAIN STORAGE BIN.—L. H. DICKELMAN, Forest, Ohio. The invention relates to storage bins more particularly for storing rice. An object is to provide a portable grain bin which is composed largely of sheet metal, having means for automatically ventilating the rice or grain thereby preventing the overheating of the same and obviating the necessity of "turning over" the grain or handling it otherwise to prevent overheating, at the same time preventing the admission of sufficient air containing moisture, which might be detrimental to the grain.

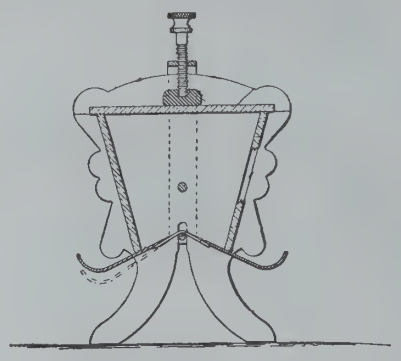
### Of General Interest

DISPLAY CARTON.—R. VAN IDERSTINE, 286 Park Ave., Newark, N. J. Among the objects of the invention is to provide a box construction comprising a plurality of interfitting or telescoping parts, which will at all times provide a connection so as to prevent the possibility of the parts becoming separated or lost, but still to permit free relative movement between the parts and to permit the parts to be readily arranged in a position most effective for purposes of display.

PRINTED BOOK.—H. W. HAIGHT, Cranford, N. J. The object of the invention is to provide a printed book or block for school purposes, more especially designed to restrain a scholar from looking ahead of the page being used. In order to produce the desired result the leaves of the book have applied thereto a fastening means such as glue or other adhesive substance to fasten the leaves along the top, bottom and sides, the fastening means having an interrupted portion to allow the insertion of a paper knife or other tool between the adjacent leaves.

COMBINED HANGER AND FRAME PROTECTOR.—J. GREENWALD, 940 3rd Ave., New York, N. Y. This invention relates particularly to picture frames. The object is to provide a corner piece which cannot be seen from the front, but which will protect and reinforce the frame in such a manner as to prevent separation while at the same time presenting a construction wherein a suspending cord may be readily secured thereto.

DELIVERING APPARATUS.—M. BONO, 60 E. Houston St., New York, N. Y. The invention relates to a delivering apparatus, and more particularly to a sanitary receptacle especially adapted for delivering toothpicks. It



A TRANSVERSE SECTIONAL VIEW, PARTLY BROKEN AWAY

is one of the primary objects to so construct the device that its delivering mechanism may be adjusted to operate to deliver one or more articles as desired. The receptacle cover is retained in place by the adjusting means of the delivering mechanism.

CARD FILE.—W. L. DINSMOOR, 925 Geary St., San Francisco, Cal. More particularly this invention has in view to produce a file employing index cards on spindles and so arranged as to provide a convenient means for keeping a file of business cards of patients or clients of professional men; however the device is adapted for other purposes of filing, or for holding calendar cards.

DOLL.—M. J. DUFF, 75 Hadden St., Bridgeport, Conn. The primary object of the invention is to provide a figure toy and construct the same in such manner that any one of a plurality of different expressions for the face may be obtained. A further object is to construct the figure entirely of cardboard, paper or the like, thus greatly decreasing its cost of manufacture.

PROCESS FOR MAKING NON-INTOXICATING BEVERAGES.—W. WILHELMY, SR., 139 N. Clark St., Chicago, Ill. This invention relates to the manufacture of non-intoxicating beverages with nearly the usual equipment of a modern brewery, without the use of special apparatus. The process consists of adding yeast to thin wort containing extract of hops at a moderately high fermenting temperature, allowing to stand for a predetermined period, reducing to a cooling temperature, and allowing to stand at such temperature for a specified time, adding a body giving substance and finally carbonating the beverage.

CHAIR SWING,—J. W. SPARKS, Clear Lake, Iowa. The invention has for its object to provide a chair swing which will be comfortable for a child, which will prevent the child from slipping or falling out, and which can

A VIEW IN SIDE ELEVATION PARTLY IN SECTION

be collapsed and packed in a small space when not desired for use. A further object is to provide a swing of the character stated, which can be adjusted to the height desired, and which will be strong and durable.

CLASP.—S. SCHRANTZ, 5938 Niverna Ave., St. Louis, Mo. This invention relates particularly to clasps for spectacle cases. An important object of the invention is to provide a clasp for spectacle cases which will be so constructed and disposed on the spectacle case as to be highly effective to retain the case in the desired position and at the same time will not present a projection likely to cause annoyance or discomfort to the user.

PRINTING FRAME.—D. F. YOUNKIN, 800 Coleman Ave., Johnstown, Pa. This invention has for its object to provide a frame adapted for all classes of printing, but especially for printing from tracings, for instance, of greater length than the frame, the frame being so arranged that the tracing may be drawn through the same to permit every portion to be printed from, and wherein a form of lock for the frame is provided.

SWAGGER STICK.—J. M. CALLAHAN, 17 "S" St., N. W., Washington, D. C. The invention relates generally to swagger sticks and more particularly to a stick comprising a handle having an engaging implement at one end in the form of a hook for the purpose of permitting of practical use of a device of this character in many instances of ordinary every day life, for instance, engaging the hand strap rail, or seat rail of a street car or other objects encountered, and in the nature of disease spreaders.

APPARATUS FOR FORMING GUN BARRELS.—W. F. COLE, 901 Amicable Bldg., Waco, Texas. The invention relates particularly to the manufacture of gun barrels having smooth bores of elliptical shape, twisted uniformly and adapted to replace gun barrels having the usual internal rifling. An object is to provide an apparatus whereby a cylindrical tube may be slightly flattened along a uniform helical line for either its entire length or the greater portion of its length.

DRIP DEVICE.—W. H. GROVER, Bay Shore, N. Y. The invention has for its object to provide a device more particularly for dripping fruit and the like in the manufacture of jelly. A further object is to provide a device which will be entirely sanitary, which will protect the drip from contact with dust, dirt or insects, which can be conveniently located at any point desired, and which can be folded and packed in a small space when not in use.

MATCH LIGHTER.—E. J. FISHER, 109 Whitestone Ave., Flushing, L. I., N. Y. This invention aims to provide a device whereby matches other than safety matches may be readily lighted. The device is especially intended for use in hotels and stores; it is extremely simple in form, economical in manufacture, can be placed anywhere and be an ornamentation, and can be utilized in the capacity of an advertising medium.

### Hardware and Tools

SCISSORS.—C. R. STORZ, 980 Greer Ave., Brooklyn, N. Y. The invention relates to scissors generally, but having particular advantages when embodied in surgical scissors. The object is to provide a scissors with removable cutting blades immovable in position, and providing for the convenient placing and removing of the blades. Among the advantages are that the blades can be replaced by new ones for approximately the cost of resharpening, also material may be used for the blades having the highest cutting quality and which for technical reasons cannot be used for the body.

FAUCET.—A. LANDGREBE, 1724 Barnes Ave., Van Nest, Bronx, N. Y. The invention has particular reference to faucets adapted to close automatically. Among the objects is to provide a faucet of a construction adapted to be manufactured mainly of glass or other analogous sanitary material. A further object is to provide a faucet comprising a valve seat, a valve or its equivalent, and means adapted to be operated either in front or above the delivery nozzle to manipulate the valve.

VISE.—L. H. DALLARD, 110 Convent Ave., New York, N. Y. The invention relates more particularly to vises of the quick adjusting type. The object is to provide a mechanism by means of which the jaws may be readily opened to any desired adjustment without the necessity of rotating the driving screw, the invention being provided with a driving screw which is disengaged from the operating mechanism.

NUT LOCK.—B. G. PATTERSON, 1210 W. 28th St., Oklahoma City, Okla. An object of the invention is to provide a simple one-piece nut which can be manufactured at low cost, which shall be substantially the same dimensions as standard commercial nuts and which shall be capable of being locked in position upon a bolt by screwing it tightly against a load surface. Another object is to provide a self-locking nut that can be quickly applied and which can be repeatedly used without injury to either the nut or the bolt upon which it is placed.

### Machines and Mechanical Devices

CENTRIFUGAL PUMP.—R. N. TRANE, La Crosse, Wis. The invention has for an object the provision of a construction wherein the water is acted on at two stages before it is discharged from the pump. Another object is to provide a construction wherein the impeller of the pump will act on the water or other liquid in the proper manner when same is at a low speed, and will later act on the same water when at high speed for increasing in a regular manner the speed.

EXPRESSION MECHANISM FOR MECHANICAL PIANOS.—C. CONTAL and E. REQUILLART, 39 Rue Lemours, Paris, France. An object of the invention is to provide expression producing mechanism so fitted as to allow a performer to regulate at will the intensity of the different notes which may be played simultaneously both in the treble and bass so that he may at any moment decrease or increase the sound of either a single note or a group of single notes comprised in a given interval or notes distributed on the whole length of the keyboard.

TOMATO AND FRUIT SORTER AND DISTRIBUTER.—T. J. PETERS, Peters, Fla. The object of this invention is to provide means which will convey tomatoes and fruit without injury to a sorter where they will be turned over as they are conveyed to a sizer to assist in the removal of off-grade and ripe fruit; the size of which is adjustable, serving to separate the tomatoes and fruit according to size as they move to a distributer which directs the tomatoes and fruit to the packers.

FEEDING DEVICE FOR PRODUCING SPIRAL STITCHES.—H. ADLER, c/o A. & T. Mach. Co., 36 E. 4th St., New York, N. Y. The invention has for its object to provide a simple means for automatically moving a work holder transversely as it is advanced by a sewing machine feeder through the sewing process. Another object is to provide means for quickly adjusting the work holder transversely relative to the sewing machine needle, and for actuating the stopping means for the machine when the member moves transversely a predetermined distance.

CUTTER CLEARANCE GAGE.—W. DALLAS, 1120 So. 52nd St., Philadelphia, Pa. The invention relates to a precision measurement gage for indicating the proper clearance angle to be ground upon the cutting tooth of a milling cutter tool. An object is to provide a simple form of cutter clearance gage which may be applied to the tooth of the milling cutter for testing the ground angle of the tooth without removing the cutter from the mandrel of a grinding machine.

FRUIT GRADER.—E. S. LATNER, Acme, Mich. The invention relates more particularly to a machine for grading apples into given sizes. The general object is to provide a machine to facilitate the process of packing apples according to size and to provide a simple structure that will handle the fruit without bruising. The object is attained by use of a grading frame over which the fruit may roll, the frame being mounted to be oscillated and arranged for manual operation.

ROAD MACHINE.—J. H. MCLEOD, 1252 Fillmore St., Topeka, Kan. This invention has for its object to provide a machine which will work the road whether wet or dry, crushing lumps when dry and squeezing the water out of the ruts and packing the soil from the high places to the low places when wet, and afterward finishing and smoothing the road, wherein the crushing and packing is brought about by a roller having spiral ribs which work the soil as it moves thereover.

SAVINGS CLOCK.—A. G. P. WINGAARD, No. 3 Norrevold, Copenhagen, Denmark. This invention relates to a clock connected with a savings box, and arranged in such manner that the clock stops after the expiration of a fixed time, unless a coin is introduced into the coin chute. To remind the owner that time for inserting another coin has come, means is provided so that the dial, some time before the clock stops, is hidden with an inscribed cover notifying the owner to that effect.

(*Continued on page 136*)

# Lower Cost of Machining and Assembling Results From Change to Machine Made Castings

*FIG. 1. In drawing the pattern by hand the least quiver plays havoc.*

THE fundamental weakness in the making of moulds by hand is a normal human weakness.

Immediately upon completing heavy physical labor, the moulder must attempt operations which require 100% muscular control. Drawing the pattern by hand (Fig. 1) and patching the mould by hand demand a degree of delicate muscular accuracy properly comparable to the requirements of an etcher or a sculptor. Even the most skillful handwork at this stage varies sufficiently to leave a long trail of later expense in added cost for laying out, removing extra stock and often the scrapping of castings half-machined.

*FIG. 2. This actual chart-reading in contrast to Fig. 1 shows the absolutely controlled accuracy of a moulding machine in operation.*

Contrast the familiar inaccuracies of hand-moulds with the graph (Fig. 2) of the operation of a power-operated moulding machine. Although foundries, in general, may give to the casual observer an appearance of rough-and-tumble freedom, nevertheless because it is a basic process, crude, faulty foundry work is bitterly expensive later. Hence this test is employed by careful manufacturers of moulding machines, because accuracy equal to that of a Corliss engine or any fine machine-tool is an essential necessity.

The modern moulding machine is not only built to the uniformity of action shown by the graph but it is constructed to maintain throughout its life an accuracy within .0005 inch variation per inch of pattern draw. This it maintains in spite of showers of sand and dirt and a pounding of 6500 blows per day which are required to pack the sand.

In practice, what is the result of this accuracy?

The result is well illustrated in Fig. 4 which shows unretouched photographs of the same casting as produced by skilled hand work and as made from machine-

*FIG. 3. A moulding machine in action—2/3 of the machine lies below the foundry floor. The machine, by jolting, first rams the sand around the pattern. Then flask, sand and pattern are "rolled over" until the pattern can be raised mechanically by vertical draw from the sand.*

made moulds. Even to the eye the hand-made casting at the left is clearly not true to shape. Necessarily uneven hand-ramming has allowed the sand to bulge in spots under gas-pressure and the resulting hills and hollows have not disappeared in the casting in spite of painstaking slicking and patching of the mould.

On the other hand, for the machine-made casting at the right, the sand was rammed to uniform density throughout and the pattern, when withdrawn by mechanical means, came away clean, requiring no slicking to smooth the surface of the mould and destroy the even porosity of sand. This casting can be exactly reproduced hour after hour, day after day, without any variation great enough to be detected by the camera.

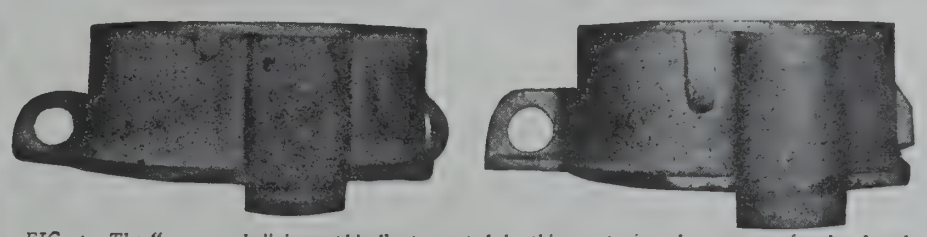


*FIG. 4. The "reason why" is graphically presented in this comparison by camera of a hand-made casting on the left and a machine-made casting on the right.*

Fig. 5 shows the second result of machine-moulding. An average of comparative costs furnished by scores of machine-shops which had previously operated on hand-made castings shows this surprising difference before and after the adoption of machine-made castings. This saving is reported as due primarily to four factors—

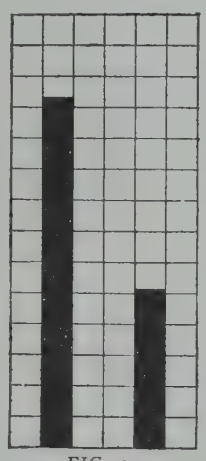

*FIG. 5*

1. Less layout work before machining because each machine-made casting is exactly like each other casting from the same pattern.
2. Less stock to be cut away on machines because of closer limits maintainable under machine-moulding.
3. Fewer castings found defective after receiving partial machining.
4. More adequate and regular supply of castings from foundry.

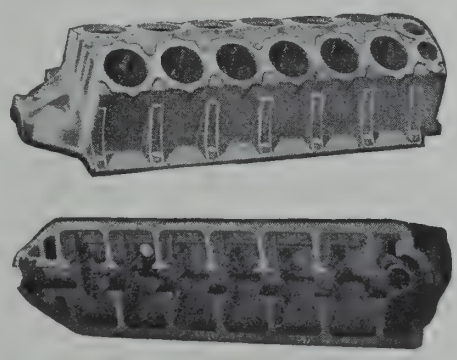

*FIG. 6. Quantity production of Liberty Motors would have been close to impossible if machine moulding had not produced thousands of uniform castings of this quality.*

In machine-shop practice certain very striking achievements have been made possible largely by the superior production-qualities of machine-made castings.

In our automotive industries lacking the advantage of foreign low-priced machine operators, rapid expansion would have probably been impossible had not the machine-made casting permitted standardization of machining operations and hence, wholesale economies. Without these economies few families could yet afford the initial cost of a car.

Shops which, during the war, operated on hand-made castings for the 12-cylinder liberty engine, and later on machine-made castings, can furnish some striking testimony as to the increased speed in handling the latter through machining and assembling.

It is largely true that in all plants where large scale production is produced by the

*FIG. 7. A 6-cylinder en bloc automobile engine casting is practically impossible except by machine-casting.*

aid of standardized operations, the machine-made casting is specified throughout. Here and there, however, still remain a few first-rank concerns which have not yet recognized the savings thus attainable and are puzzled by the fact that smaller competitors hold their own with them in cost of production. The advantage can usually be traced to the machine-made casting in the smaller plant.

The factory superintendent who has assumed that the modern moulding-machine is of interest solely to the foundryman as a means of increasing output and reducing costs will discover on even the briefest personal investigation that the subject holds for him the opportunity for equal or even greater savings. To neglect to investigate the machine-made casting is to make his competitor's path easier.

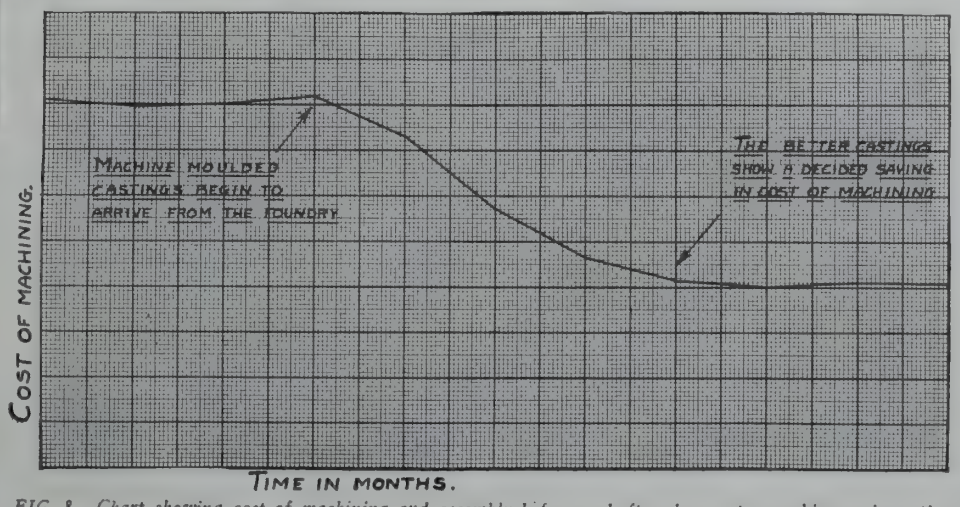

*FIG. 8. Chart showing cost of machining and assembly before and after change to machine-made castings.*

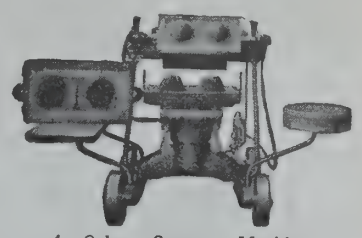
OSBORN

MOULDING MACHINES

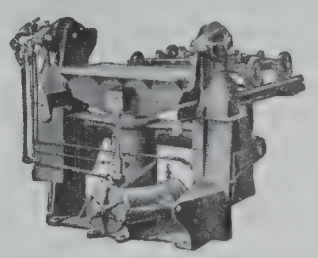
SOME picture of the world-wide acceptance of the machine-moulding process is indicated by the fact that the sales of Osborn Machines alone are today four times as great as the es-



*An Osborn Squeezer Machine*

timated total sales of all machines in the period preceding the World-War.

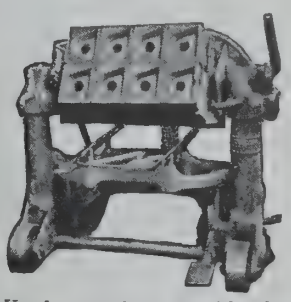
The functions of a moulding machine are three:—1. Ramming the sand by squeezing or jolting; 2. Rolling the mould over; 3. With-



*An Osborn Roll-Over Model*

drawing the pattern mechanically from the sand without damage to either sand or casting.

In Osborn practice these operations are performed either by hand-power or by air-power. The greatest saving in labor is obviously



*Hand-operated Osborn Moulding Machine*

secured by the latter but the saving in accuracy is attained by either method.

The choice and application of the proper equipment is a matter to which we give our closest attention. Let us send an experienced sales-engineer to study conditions in your foundry and make an authoritative recommendation.

Belt Joints
That HOLD

CRESCENT Belt Fasteners make a joint that lasts as long as the belt itself. The Crescent plate and Rivets take a won't-let-go grip on the belt that long, hard and continuous service cannot loosen. A Crescent joint "stays put" from first to last. It eliminates delays and breakdowns and insures continuous production.
No part of the belting is punched out or weakened in making the Crescent joint. The entire strength of the belt is maintained across the entire width of the belt, for the entire life of the belt.
The Crescent joint hugs the pulley. The belt runs the same as endless on pulley side.
Write for new booklet B on increasing Belting Efficiency and for demonstration sample.

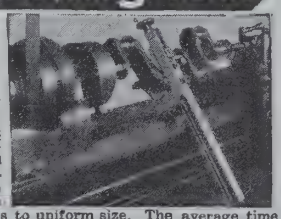
Weber Crank-Pin
Re-Turning Tool

No Filing
No Offsetting
No Jigs



This Weber Tool turns all pins absolutely round from one setting of Crank Shaft, on centers. A micrometer dial enables the operator to gauge his cuts and turn all pins to uniform size. The average time required for trueing up one pin is from 5 to 10 minutes. The 4 pins can easily be finished in 30 minutes, and the entire shaft is completed with only one setting.
**The Weber Tool is guaranteed** to turn crank-pins within as close limits of accuracy as any other known method. It will soon save its cost in any Tractor or Automobile Repair Shop. An assortment of cutting tools are furnished. These will fit the pins of most of the popular automobiles, trucks and tractors. Write for Circular and Prices.
SAWYER-WEBER TOOL MFG. CO.
353 S. Alameda St. Los Angeles, Cal.

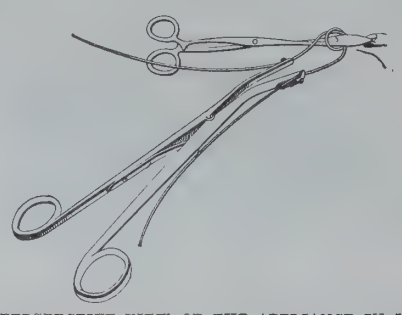
UNISOL BOILER PRESERVER
Warranted without reserve, to remove boiler scale, prevent pitting and scale formation.
Pamphlet on request. Money back guarantee.
UNISOL MFG. CO. Jersey City, N. J.

## RECENTLY PATENTED INVENTIONS

(*Continued from page 134*)

### Medical Devices

SURGICAL APPLIANCE.—L. O. ROBERTS, 146½ Kellingsworth Ave., Portland, Ore. The invention has for its object to provide an appliance of the character specified especially adapted for tying knots in ligatures in cavities



A PERSPECTIVE VIEW OF THE APPLIANCE IN USE

where it is difficult or impossible to reach with the hands. The device may be used in any cavity where it is difficult to insert the hands. In tying the knots the hermostatic forceps will be held by an assistant.

REMOVABLE BRIDGE FOR DENTAL WORK.—A. S. STONE, 133 Hegeman Ave., Brooklyn, N. Y. The invention relates to dentistry. An object is to provide a means for restoring teeth within a person's mouth and to provide a form of removable bridge work which may be fitted to sound teeth of a patient's mouth and support an artificial tooth so as to adequately fill a space left by the loss of a natural tooth, and may be removed for the purpose of cleansing the artificial members.

DENTAL APPLIANCE.—D. W. BARROW, 1216 Jas Bldg., Chattanooga, Tenn. This invention has for its object to provide an appliance intended to replace the wax bite used by dentists in obtaining occlusion for artificial teeth, which will permit true occlusion to be obtained, taking account both of the direct movement of the jaws toward each other and of the gliding movement of the lower jaw with respect to the upper.

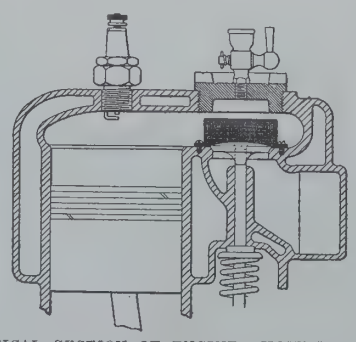
### Musical Devices

PLAYER PIANO CONTROL APPARATUS.—M. S. HOWARD, Interstate Power Co., Waukon, Iowa. The object of the invention is to provide for the employment of governors for controlling the degree of vacuum attained in the pneumatics. A further object is to provide a method of regulating the action of these governors, and to provide a method of applying the system of control to the action of the striking pneumatics of a player piano.

BANJO.—R. T. CARLUCCI, 87 Ferry St., Jersey City, N. J. The invention relates to banjos, mandolins, guitars, ukuleles, drums and similar instruments having a membrane. The object is to provide means whereby the owner of such instruments is enabled to readily detach a cracked, split or otherwise injured membrane and its mounting and forward the same to a manufacturer for replacing such membrane by a new one, and when received by the owner to allow the latter to reassemble the parts without the aind of a skilled instrument maker.

### Prime Movers and Their Accessories

CARBURETING SCREEN FOR INTAKE VALVES.—F. W. LAPHAM, 5036 W. 22nd Place, Cicero, Ill. This invention relates to screens for intake valves of internal combustion engines. An object is to provide a hood and means for clamping the same in place over the intake valve of an internal combustion engine, the hood being made of wire mesh, the



VERTICAL SECTION OF ENGINE SHOWING INVENTION APPLIED

structure being such that it will become heated during the use of the engine and will thereby distribute the heat to the incoming fuel so as to gasify the fuel even though the same may be of the more or less heavier kind as, for instance, kerosene.

VALVE GRINDER.—W. L. DINSMOOR, 925 Geary St., San Francisco, Cal. This invention relates particularly to valve grinders adapted for grinding valves of internal combustion engines. An object is to provide a grinding tool having means to engage the valve and vibrate the same back and forth on its seat for effective grinding and adapted also to be given a movement to optionally shift the valve to vary its position on its seat during the grinding operation, the shifting of the valve on its seat being necessary for true grinding.

### Railways and Their Accessories

AUTOMATIC TRAIN STOP.—F. J. MCAVOY, 496 Clinton Ave., Newark, N. J. This invention has particular reference to means for automatically controlling the running of trains in connection with the usual Westinghouse air-brake equipment. Among the objects is to provide obstacle mechanism associated with one of the rails of the track and including a vertically movable plunger adapted normally, when the track is clear, to be substantially flush with the rail over which the wheels pass, but when the block is occupied, or the signal mechanism set at danger, will project upwardly above the surface of the rail subject to being depressed by each wheel rolling on the rail.

LOCOMOTIVE CRANE SANDER.—T. H. COCHRANE, 168 Wilkinson St., Jersey City, N. J. An object of the invention is to provide a track sander device which is readily attachable to a locomotive crane of present day use. It is a purpose to provide a design of sanding device which will adequately funciton on a locomotive crane to the same effect and for the same purpose as the sanding device now applied to ordinary locomotives.

GRAIN DOOR.—N. SMITHBACK and W. H. MEIER, 17 W. Main St., Madison, Wis. The invention relates to grain doors generally and more particularly to grain doors which swing horizontally and are adapted especially for use with grain cars or the like. An object is to provide a door of this type which is leak-tight in closed position, with an outwardly swinging section and inwardly swinging sections, the inwardly swinging sections being positively prevented from swinging outwardly beyond the closed position of the door.

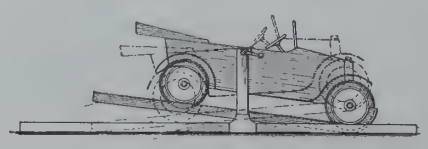
CONCRETE RAIL AND TRACK.—W. J. PLATTEN, 218 Oakland Ave., Green Bay, Wis. An object of the invention is to provide a concrete track which is stronger, more permanent and cheaper to maintain than the ordinary steel rail and wooden tie track in common use. A further object is to provide a rail and track construction which will prevent the usual sagging of the rail, in which an economy is effected in the use of steel, and in which the rail is held to the base by means of clamps which are adjustable, and which lock the rail in position, positively held from spreading apart.

### Pertaining to Recreation

AMUSEMENT APPARATUS. — E. S. DOUGHTY, 417 4th St., Red Wing, Minn. The invention relates to a trackway comprising a pair of side plates and a series of treads connected with the side plates, means for supporting the trackway in elevated position, which may be varied to suit conditions, mechanism for permitting the trackway to be set up where desired, and taken down and folded for permitting of storage or transportation.

### Pertaining to Vehicles

AUTOMOBILE JACK.—W. H. BUTTERS, 715 Center St., Calgary, Alberta, Canada. The object of this invention is to provide a jack on to which an automobile can be easily run and



A SIDE ELEVATION OF THE DEVICE

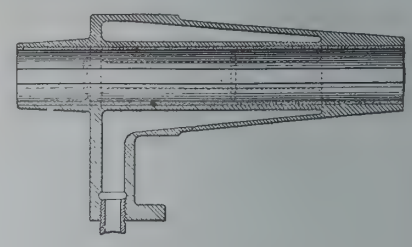
can be elevated or tilted to any desired angle and held in this position as long as desired. A further object is to provide a construction of carrier and means for operating the same to elevate and lower the automobile.

AXLE RECONSTRUCTION.—J. R. FLEMING, 801 Monroe Ave., Scranton, Pa. Among the principal objects which the invention has in view are, to avoid waste of partially worn axles, to renew service conditions in journals for wheels and similar members, to avoid loss of time in repair on car construction, and to add to the construction without weakening the part added to.

CART.—J. HINTZ, 2726 N. Lawndale Ave., Chicago, Ill. An object of the invention is to provide a small cart or wagon which has a rocking chair seat, and which may be propelled by the occupant of the chair in rocking back and forth. A further object is to provide a novel form of cart or car which is simple in construction and relatively cheap to manufacture.

VALVE.—G. W. THOMPSON, Cheboygan, Mich. This invention has for its object to provide a valve adapted to be interposed in the fuel supply line of a motor vehicle, and in the oil line for controlling the flow of the fuel to the carburetor and having means normally operative to cut off the fuel supply, but controlled to inoperative position by the flow of oil through the valve, the arrangement being such that when the oil does not flow the motor will be stopped.

VULCANIZER.—E. D. HOSTLER, c/o Haiiiel & Mather, Tipton, Iowa. More particularly this invention relates to a mandrel for use in vulcanizing the ends of the inner tubes of automobile tires and the like, an object being to provide a device which permits the tube



A LONGITUDINAL SECTION OF OUTER SURFACES OF THE MANDREL

ends to be vulcanized on the outside thereof, thus permitting a ready manipulation of the tube so as to insure a proper positioning of the parts and also permit of full observation of the vulcanizing process.

NON-SKID FOR WHEELS.—F. HUDA, 469 Division St., Perth Amboy, N. J. The invention has particular reference to means for applying short chains to wheel tires. Among the objects is to provide a simple device for attaching a chain to a wheel felly especially a wooden felly, the chain being adapted to pass transversely over the outside of the tire from one side of the felly to the other, means being provided for the most convenient attachment, and positive holding to the sides of the felly as distinguished from the inner surface thereof.

APPARATUS FOR UTILIZING THE TREPIDATIONS OF VEHICLES.—M. A. CANALE and R. FRIAS, Calle Maiper, 671, Buenos Aires, Argentina. This invention relates to an apparatus for the purpose of utilizing the trepidations and shaking movements originated by the varying of level in any kind of vehicle, transforming them into a rotary motion of sufficient intensity so as to be able to set in motion any kind of apparatus which requires slow speed to work.

### Designs

DESIGN FOR A PURSE.—C. A. NICHTHAUSER, 32 Union Sq., New York, N. Y. The inventor has been granted patent on two designs of a similar nature.

DESIGN FOR A RUBBER HEEL PAD FOR BOOTS AND SHOES.—J. E. BARNEY, address Pioneer Products Inc., 30 E. 42nd St., New York, N. Y. The invention has been granted three patents of a similar nature.

DESIGN FOR A TOOTHBRUSH CASING.—E. H. WIERSCHING and E. K. WIERSCHING, 249 Main St., Susquehanna, Pa.

DESIGN FOR A POWDER CONTAINER.—C. S. HUMPHREY, c/o Manhattan Can Co., Bush Terminal No. 10, Brooklyn, N. Y.

DESIGN FOR A SANITARY FOUNTAIN.—T. LLOYD, 1 Taylor St., Boston, Mass.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## In the Wake of the Woodsman

*(Continued from page 122*

abundantly. Experiments with eroded soil prove that much of the soluble salts are washed out. The Department of Agriculture found that in all the constituents excepting potash non-eroded soil was much richer. The greatest difference was in nitrogen, one of the most important of plant foods. This is because a large proportion of the nitrogen compounds are readily soluble in water and were carried off. Not only was the fertility of the soil destroyed but its water-holding capacity was reduced from 67.2 per cent to 46.8 per cent. More water was required to produce a very inferior plant growth on the eroded soil.

Only the very hardiest, and usually the most useless, of plants can gain a foothold on eroded ground and it may be decades after the plants gain a stand before the ground will have sufficiently recovered its fertility through decay of vegetation to support the plants which formerly grew on it abundantly.

When water has finished its destructiveness on barren land, the wind has its innings. Where the eroded area is of wide extent, the wind, unhindered by trees or vegetation, continues in dry weather what the rain has begun, and often six or eight inches of soil will be removed in spots by a single windstorm.

But not only is harm done to the soil. The amount of moisture evaporated into rain clouds is much less where there is no vegetation and a drier climate results. Windstorms are unobstructed and more frequent. This may account, in a measure, for the increasing number of destructive tornadoes in the Middle West in recent years.

One of the principle causes of erosion in the Middle West is over-grazing of cut-off forest lands. Grazing within reasonable limits is not harmful but where sufficient cattle are turned on the land to crop the vegetation close and pack the soil, the future usefulness of the soil is almost sure to be destroyed. A single big rainstorm, under such conditions, may carry away the accumulated vegetable decay of ten years. Once erosion sets in the destruction is sure and rapid, and any known process of rebuilding the soil is slow and uncertain.

The conclusion is obvious; our remedy must be prevention. If care is taken to see that a good stand of seedling trees is left in cut-over forest areas, these only need protection from fire to insure a second crop of timber. Our Forest Service has done wonders with the meager funds as its disposal, but the funds are entirely inadequate. It is estimated that an adequate forest policy would be self-supporting within a very few years. But even if it were a constant expense our lawmakers should be willing to undertake it to insure against a repetition of China's case.

But the problem must be solved not only in the care of our national forests, but in the preservation of our farm woodlands. The farmers own as large an area of woodland as the lumbermen and all others combined. Much of the hardwood supply of the country comes from this source.

The farmer uses most of the product of these lands himself, either as cord wood or for other farm purposes. He usually regards his woodlot as a sort of reserve and when he is in need of ready cash, he cuts off the trees and sells them. As a result few farm woodlands are fully stocked with trees and fewer still have trees which yield the best crop. A campaign of education needs to be undertaken, but such campaigns are expensive and there are no funds available. In this connection it ought to be remembered that not only is the problem one of forests; every single tree whether it be in a city street or a country field plays its part in the regulation of winds, climate

# They Chose St. Louis

THIS $5,000,000 plant of the General Motors Company is one of almost 100 new plants, and a total of 15,000,000 feet of floor space, built in St. Louis in the last two years. In one industrial district alone new industries have been established costing more than $20,000,000 and employing 14,000 workers. The new factories built 8,000,000 feet of floor space, and the already established St. Louis industries expanded 7,000,000 feet.

Why were these big plants built in St. Louis? This general movement to the one point was not an aimless change of location, but was the result of a businesslike investigation of production and distribution advantages.

These industries spent millions of dollars in locating at St. Louis so as to be near the center of economic distribution, near the center of raw materials, and within easy reach of the markets in every direction. Twenty-six railroads and the Mississippi River carry their goods to all markets.

The business men of St. Louis are awake to the advantages of the city, and are seeking sixteen specific industries to manufacture goods for which there is a need and a profitable market in the St. Louis trade territory. These industries are:

*Shoe laces and findings*
*Cotton spinning and textile mills*
*Dye stuffs*
*Steel and copper wire*
*Machine tools and tool machinery*
*Automobile accessories and parts*
*Drop forge plants*
*Tanneries and leather products*
*Malleable iron castings*
*Farm implements*
*Rubber products*
*Screw machine products*
*Locomotive works*
*Blast furnaces*
*Cork products*
*Small hardware*

The booklet "St. Louis as a Manufacturing Center" gives details that will be interesting to you. A letter will bring it if addressed to

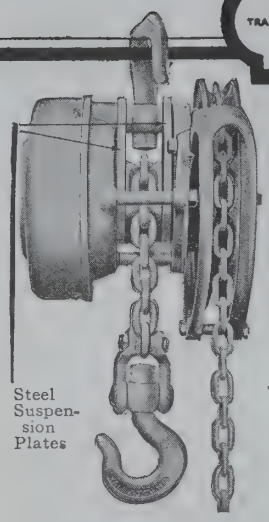
YALE TRADE MARK



Steel Suspension Plates

## The Block With Safety Built Into It

SOMETIMES your chain block, in its lifting of raw materials, parts, or cases of finished product, will be subjected to severe shocks or overloads.

Ordinary cast suspension members might break under the strain. But the steel suspension plates of the Yale Spur-geared Block safely carry the load.

The economy of the speedy, powerful Yale Chain Block, or Electric Hoist makes it the first choice of the careful buyer.

Yale Chain Blocks are carried in stock by all representative supply houses. Our new Hoist Catalog explains the details. Write for it.

and rainfall. The American Legion has been highly commended by forest experts for its policy of planting trees as memorials to fallen heroes.

The observation of Arbor Day by school children has resulted in the planting of thousands more of trees which will be preserved largely because of their sentimental value.

There is hardly a man but who at some time or other has to make a decision as to whether a tree shall stand or fall. It is the part of patriotism whenever possible to let it stand.

### The Last Word in Searchlights

(*Continued from page 123*)

degrees. It has a grid of five coils mounted in a single plane. Of course, to operate these lamps on land, transformers or resistances are required, depending upon whether the circuit is alternating current or direct current. The 32-volt lamp will operate with no appurtenances on the average boat circuit, which is usually of 32-volts pressure. The globes for all these lamps are of hard glass, lead glass being too soft to withstand the tremendous heat generated.

Beginning this year, sane Fourths of July can take on new glory with the brilliant aid of these incandescent searchlights. Spectacular color effects and beautiful ground and aerial displays have been worked out by engineers for scores of great outdoor night pyrotechnics such as those at the Panama-Pacific Exposition, the Hudson-Fulton celebration and other illuminations nationally famous. Many of these have adaptations which could be used and doubtless will be used in "fireless fireworks" shows of the future based on incandescent searchlights which cost less, operate more economically and are far more adaptable to varying conditions than are searchlights of medium size.

### Guiding Ships by Electric Cables

(*Continued from page 123*)

been put in operation at Portsmouth, one to indicate the entrance channel and the other for the exit channel. The entrance cable starts from a powerful electric station provided with a wireless outfit and runs to a point 1,454 meters to the south, 4 degrees west of Horse Sand Fort, this first part being laid upon a very shallow bottom is not intended to be employed as a guide. The cable then follows the passage southward 63 degrees east for a distance of 10 kilometers, after which it runs 13 kilometers to the south, 1 degree west and 2 kilometers to the south, 6 degrees east. At this point the end of the cable has reached the latitude 53°, 33′, 36″ north, and a longitude of 0°, 56′, 42″ west at a depth of 27 meters. The entire course covers 30 kilometers.

By interrupting the current at given intervals corresponding to dots and dashes of the Morse telegraph code, ships provided with suitable galvanometers or indicators are able to recognize their position as regards the cable at distances of from 400 to 500 meters.

The signal transmitted is the letter V or the letter X, and certain devices enable the ships to signal how far they are from the terminus. Ships which desire to make use of this guide cable, either for maneuvers or to make port, must notify the Block House Fort at least half an hour in advance and must state the time during which they expect to use the cable. Ocean ships communicate by wireless with the Culver Cliff Station which relays the message to the Block House Fort, and the latter acknowledges the receipt of it and advises the ship of the time when the alternating currents are sent. The cable is marked 2946 and 2650 on the Admiralty charts. The matter has already attracted interested attention in France, and will doubtless do so in this country. It seems highly probable, too, that the Marine Insurance companies will vigorously push the plan of having ports difficult of access thus safeguarded, since the initial expense is small compared with the loss of even a few boats.

### Who Invented It First?

(*Continued from page 124*)

and received a patent on this same style of clip. Mason immediately filed an application for patent for the same thing, claiming that he was entitled to the patent because he had invented it seven years before and produced the clip and the witnesses to prove that such was the case. The court admitted that he had completed the invention as claimed, but refused to grant him the patent because he had not disclosed his invention to the public, but had concealed and suppressed it. They quoted with approval from a case decided by the Supreme Court of the United States many years ago:

"The inventor, who, designedly and with a view of applying it indefinitely and exclusively for his own profit, withholds his invention from the public, comes not within the policy or objects of the patent system. He does not promote, and if aided in his design would impede, the progress of science and the useful arts; and with a very bad grace could he apply for favor or protection of that society which, if he had not injured, he certainly neither benefited nor intended to benefit. Hence, if during such a concealment an invention similar to or identical with his own should be made and patented or brought into use without a patent the latter could not be inhibited nor restricted upon proof of its identity with a machine previously invented and withheld and concealed by the inventor from the public."

While the great part of the conflicts as to the right to a patent arises between independent inventors, there are cases where the rival claimants do not know of each other's activities. In some of these cases it looks as though there were a deliberate attempt on the part of one party to appropriate the invention of another. Cases of this character are few and are decided according to the same rules as would be the attempt of another to appropriate your watch to his own use. A fact not to be lost sight of is that when anyone makes application for patent he makes oath to the fact that he verily believes himself to be the original and first inventor. False swearing is punishable here as in any other instance of false swearing. Cases which on the surface look like attempts at appropriation, when simmered down often show that such inventor really believes that he and not his rival was the real inventor.

There is another situation wherein the rival claimants for a patent are aware of each other's activities. It arises out of the employment of one individual by another as a result of which the invention is brought to a practicable form or state of perfection by the employee. This can be illustrated best by a decided case. A was the superintendent of a concern manufacturing iron bedsteads. He brought to the foundry of B's company, for the purpose of having a casting made of it, a wooden model of a device for connecting the rail and post of an iron bedstead. He was referred to B as the pattern maker. Some conversation ensued between A and B during which B pointed out some faults, as he considered them, in the model. A went away but returned in half an hour and in the interview then had between himself and B, the latter suggested the introduction of a headed rivet in the model. To this suggestion A acceded, and at the request of B subsequently brought to the latter a section of pipe such as is used in beds, with a headed rivet attached from which B made the model from which the castings were made which were subsequently used in a bedstead. A conceded that the feature of the headed rivet was B's suggestion, although the headed

**BUSINESS OPPORTUNITY**

SUBSTANTIAL manufacturing corporation wants capable men to establish branch and manage salesmen. $300 to $2000 necessary. Will allow expenses to Baltimore as explained. Address, Mr. Clemmer, 603 N. Eutaw St., Baltimore, Md.

rivet was only one element of the invention. The court decided that the invention including the headed rivet belonged to A. The law governing cases of this character was laid down by the Supreme Court as follows:

"Where a person has discovered an improved principle in a machine, manufacture or composition of matter and employs other persons to assist him in carrying out that principle and they in the course of experiments arising from that employment make valuable discoveries ancillary to the plan and preconceived design of the employer such suggested improvements are in general to be regarded as the property of the person who discovered the original improved principle, and may be embodied in his patent as part of his invention."

This rule of law as stated by the Supreme Court is a just one and is based on the general equitable principle that a person cannot be permitted to make capital out of a fiduciary relationship. If the employe had never been taken into the confidence of the employer and entrusted with the underlying principle of the invention obviously he could never have made his improvement. However, if the employe, after the ideas of the employer had been communicated to him devised an independent invention not dependent in principle upon the plan suggested to him by his employer, the employe is entitled to receive the patent therefor.

## Our Deep-Sea Freighters

*(Continued from page 126)*

facilitates the handling of either fuel oil or water ballast. The sixth compartment is for the storage of fresh water.

The propelling machinery consists of one Curtis General Electric marine turbine, with double reduction gear, and is capable of developing 3,000 shaft horsepower. When a 17-foot propeller is making 90 turns a minute a speed of 11 knots an hour is realized. The turbine is constructed to operate on steam at a pressure of 200 pounds, with 40 degrees superheat. The turbine rotors can be reversed instantly and are designed to maneuver at half speed—a special valve is provided which admits the steam to either the ahead or the astern rotor. This arrangement provides a desirable degree of operative flexibility. Steam is furnished on each of these boats by three single-ended Scotch marine boilers having a total heating surface of about 8,400 square feet. The boilers are equipped with a forced-draft system, and their oil fuel outfit is of the mechanical burner type. It is said that the double-reduction turbine drive has functioned successfully under severe sea-going conditions.

The ships have numerous winches, conveniently placed, which, with the several 5-ton derricks, are able to handle cargo in a thoroughly expeditious manner. It is a source of satisfaction to know that these freighters have shown themselves to be admirable in many ways and to represent a type which should become conspicuous in our fleet of trade. They are especially suited for the handling of bulk commodities by reason of their distinctive method of construction.

The Isherwood system is primarily designed to afford great longitudinal strength so as to resist the lengthwise stresses set up in a craft exposed to the open seaway. Likewise, the form of structure adopted in this system is intended to promote transverse rigidity so as to offset forces likely to induce diagonal distortion. The ordinary ship is of the so-called transverse-framed type, and lacks in some respects the stiffness which is obtained by the deep frames installed at suitable intervals in craft of the Isherwood pattern. These frames are in effect continuous athwartships because they extend under each deck and rise to the upper limits of the hull.

Analyses of ships of identical dead-

# Five Weeks of Salt Water!

Down at a big Baltimore shipyard a piece of portable electric cord became wedged in a piling under the salt water. It could not be pulled out but they kept on using the tool with the cord submerged.

That cord was Duracord. And after 5 weeks of salt water it was still going strong!

**DURACORD**
TRADE-MARK

has a thick, heavy covering *woven* like a piece of fire hose, that withstands oil, gasoline and hard usage just as it shed salt water. It increases efficiency and keeps down costs. It will add to the value of any electrical tool, machine or hand lamp equipped with it.

Duracord can be furnished in all sizes of portable electric cord and also in the larger sizes of single and duplex cable. Ask your electrical jobber about Duracord or let us send you samples of Duracord and ordinary cord for you to test and compare yourself.

**TUBULAR WOVEN FABRIC CO.**
**Pawtucket, R. I.**
*Makers of Duraduct*
*Flexible Non-Metallic Conduit*
*and tubular woven fabrics of all kinds*

*This is Duracord. Thick, heavy strands, woven like a piece of fire hose, not braided. Picture shows outside covering only with impregnating compound removed.*

*Here is the ordinary braided cable covering. Note the open and porous construction easily cut, stretched or unraveled. Compare it with the illustration of Duracord.*

SONNEBORN PRODUCTS

SAVE
WHAT YOU HAVE

**You write off in your books a certain amount each year to DEPRECIATION but—you can save a good share of this amount by putting a stop to the actual DETERIORATION of your plant.**

**Look to your floors, walls, roofs, stacks and pipes.**

**Protect them with Sonneborn Conservation Products—make them last longer and serve better. Stop their costly deterioration.**

**Look over this list of Products—and decide how and where they should be used now in your plant.**

For Concrete Floors

LAPIDOLITH TRADE MARK makes concrete floors dustproof, wearproof and non-absorbent.

Lapidolith is the liquid chemical which fuses the concrete into a granite-hard mass which cannot dust, or disintegrate even under heavy trucking.

Concrete dust ruins merchandise and machinery. Floor repairs are costly.

Avoid both—just flush on Lapidolith.

70,000,000 square feet of concrete floors were lapidolized in the last two years. We can refer you to such a floor in your vicinity.

Write for testimonials and sample of lapidolized concrete.

For Wooden Floors

**LIGNOPHOL** preserves wooden floors and prevents splintering, rotting and wearing.

Treat new wooden floors with Lignophol—keep them new and resilient with life of new lumber.

Save the cost of new flooring. Old floors can be saved for years of service by this tonic wood filler.

For Pipes

**PIPE ENAMELS** will withstand extremes of heat and cold without stripping or peeling. Not affected by chemical fumes. Furnished in colors to assist in pipe identification

For Walls and Ceilings

*Cemcoat* This mirror-like mill white multiplies the natural and artificial light by reflecting it from every angle.

Cemcoat furnishes more light in its cheapest form—reflected light.

This additional light is needed to speed up production and produce more profits. Cemcoat costs less than common paint because it lasts longer. It holds its whiteness and can be washed without injury.

Gloss Cemcoat for interiors. Flat Cemcoat for exteriors. Furnished white and in colors. Send for color card.

For Roofs

**STORMTIGHT** is the asbestic coating which gives absolute protection to old or new roofs. Saves tearing up old roof and cost of new roof, also painting and repairs. Apply it to any roof surface.

For Stacks

**BLACK STACK PAINT** protects the stack against extreme heat and from weather conditions. Used and recommended by leading plant owners because of its universal durability.

For Galvanized Surfaces

**GALVACOTE** adheres perfectly to any galvanized surface, overcoming the greasy film which causes ordinary paint to strip and peel.

*Write for literature and information regarding any of the Sonneborn Products*

Incorporated

*An independent company that produces and refines its own petroleum*

weight cargo capacity but dissimilar so far as the substitution of the Isherwood system is concerned, go to show that the latter method permits of a material saving in weight of steel while insuring a somewhat sturdier structure. It is claimed for the Isherwood-built craft that she is easier to clean and to paint inside—thus promoting better upkeep and lessening the likelihood of unsuspected deterioration. Finally, because of the larger measure of free space in the holds, the advocates of the type say that the Isherwood vessel can carry two per cent more cargo. To put it popularly, we are told that thirteen cargo carriers built on the Isherwood system requires only the same weight of steel as that needed to produce twelve ships of ordinary construction of the same dimensions!

While the Isherwood craft does call for more small fitting work than the transversely-framed boat, still this is discounted by a smaller amount of heating and bending of shapes. In putting an Isherwood steamer together, the erecting can be carried out with greater ease and economy than is commonly the case with the older and generally prevailing practice. And then during the building period the Isherwood ship can be assembled deck by deck—floor by floor as we would say in house building—and this reduces, accordingly, the heights to which materials must be raised while the hull is growing. In the transverse-framed vessel, on the other hand, the frames are erected at the very start to their full height, and everything going aboard for any stage of the work must be lifted up and over the tops of these frames to reach a point within them.

There was a time when we gave little heed to items of this sort, but it must be plain to the thinking person that it takes longer, requires a bigger expenditure of power, and costs just so much more to lift or move any weight a foot in excess of actual requirements. Considering, then, the thousands of pieces of metal and equipment that are brought into place while a ship is still on the blocks, it should be manifest that the Isherwood system reveals how substantial economies can be effected at the very start.

## The America's Cup Races

(*Continued from page 128*)

at any port in which she might find herself for the time being.

The final and decisive race, held July 27th, was won by "Resolute" in a light and variable breeze. "Shamrock IV" led across the line, and Mr. Burton had "Resolute" under her lee. And then followed one of the greatest surprises of these contests; for in the light air of 3 to 5 knots, "Shamrock" succeeded in holding the weather position for over two hours. The start was made at 2h. 17m. and it was not until 4h. and 23m. that "Resolute" succeeded in crossing the challenger's bow. Once clear of "Shamrock," "Resolute' began to draw ahead, and turned the outer mark at 5h. 18m. 35s. "Shamrock following at 5h. 22m. 42s. The "Resolute" gained some 9 minutes on the last leg and finished with an actual lead of 13m. .05s, and a total lead, including time allowance of 19m. 45s.

Thus was concluded the most closely contested series of races ever held on the Sandy Hook course. Sir Thomas Lipton, with the first two races to his credit, came nearer to winning the cup than any of his predecessors. Only once in the past sixty-nine years has the challenger taken a race. That happened in 1871, when the defending yacht, "Columbia," was disabled, and the race went to "Livonia."

Sir Thomas does not take back the Cup, but he does carry with him the warm regards of the American people, and their high appreciation of a sportsmanship which accepts defeat after defeat with a smile and with words of congratulation to the victor.

## The Romance of Tungsten

(*Continued from page 130*)

tungsten was found useful in certain steel alloys. Mixed with an adhesive it was made into lamp filaments that were efficient but exceedingly fragile. However, no metallurgist was able to discover a way to work tungsten separately. This was because in pure metallic form it is absolutely brittle. It confounded all experts with its utter intractability. The established processes in working other metals proved useless with tungsten.

Perhaps it was this very thing which finally brought about the harnessing of this valuable metal. Because it had so steadfastly refused for more than 100 years to respond to the arts of the metallurgist, Dr. Coolidge, with the instinct of the true scientist pioneering in untrodden fields, tried ways that any metallurgist would have thought an idle waste of time. The result was that after long effort and many failures he finally made tungsten ductile and workable so that it could even be drawn like wire down almost to the gossamer fineness of spider's web and still be strong enough to permit its winding and curling into almost any shape. When he had done that he had conquered tungsten and made possible many devices which could never have been built without ductile tungsten.

The radical difference in workability between tungsten and normally ductile metals, the difference which nonplussed the scientific world for more than a century, may be explained thus:

Pure tungsten pressed into bars is brittle after the very treatment which makes other metals most ductile. It differs from all other ductile metals in that when composed of grains it is extremely brittle at "room temperature," but is ductile at this temperature when fibrous.

Many an experimenter had sought to work tungsten mechanically, but none had ever succeeded in getting this intractable metal into a form suitable for mechanical working. Moissan, by an electric furnace method, obtained tungsten in a porous condition which could be slightly compressed and the pores closed up by hammering when hot. However, nobody in the world suspected at that time that if tungsten could be obtained and put into suitable condition and then mechanically worked at suitable temperature, its inherently brittle nature would gradually disappear. But nobody knew how even to make a start upon the problem of working tungsten.

To make any ordinary metal soft it is heated above its annealing point and then cooled down to room temperature. Doing this to tungsten, however, left it as brittle as ever.

Violating all metallurgical rules and working for years with utmost patience, Coolidge discovered the astonishing fact that the only way to make tungsten ductile was to mash tungsten's grains out into fibrosity and thus make the metal ductile cold and this he did by first heating it to a degree below its annealing point and then mechanically working it with infinite pains at a variety of heats each cooler than the one before until the metal got down to room temperature. A similar treatment, if applied to ordinary metals would destroy their ductility.

He worked out a process which, if followed without the slightest deviation, stretched the grains out, thus attaining ductility. But if the working varied from his process, failure resulted. The tungsten would smash to flinders at a stroke when it got cold.

This elaborate and delicately measured system of working tungsten is a scientific triumph.

Thus was tungsten finally made ductile.

The greatest immediate use for it was in the making of electric lamp filaments. Previously the best filament was made of fine tungsten powder, mixed with a binder into plastic mass which was squirted

through fine dies to produce fragile "wire."

This was an enormous improvement over the old-style carbon filament, thanks to the fact that tungsten, with a melting point of 1,350 degree Centigrade, will stand more heat than other metals and its vapor tension is so low that even under tremendous heats its volatile decomposition is slow. Tungsten even in this form made so good a lamp that it saved the American public a billion dollars a year on its electric light bill.

But filaments of those days could not withstand the slightest jar during the process of manufacture. They necessarily could not be strongly mounted in lamps.

Pure tungsten on the other hand drawn into filaments can stand almost anything. For one thing it is one of the heaviest metals. Whereas wrought iron weighs 490 pounds per cubic foot, and lead 708 pounds, tungsten tips the beam at 1,193 pounds. Its tensile strength is startlingly high. After it has been worked down to drawn wire of about a thousandth of an inch diameter its tensile strength is no less than 600,000 pounds per square inch of cross section. This is greater than the best piano wire.

To produce tungsten from sheelite or wolframite the ore is fused with alkali carbonates and the fusion dissolved in water. This may be changed to tungstic oxide by adding acid. The oxide, a yellow precipitate. is then filtered off. The tungsten oxide is purified to any desired degree by dissolving it in ammonia and then precipitating by adding acid, followed by filtering and washing.

To use tungsten in lamp manufacture, it is dried, mixed with thorium nitrate solution and then thinned with water into a batter. This is dried and heated at 2,000 degrees Fahrenheit for an hour in a silica or fire clay crucible to agglomerate the fine particles into coarser ones. This mixture is reduced by hydrogen at 1,800 degrees Fahrenheit into tungsten metal powder.

The reduced tungsten powder is poured into a steel mold which is a slab whose face bears a groove a quarter of an inch wide and deep. Under hydraulic pressure of 16 tons per square inch this groove full of powder is pressed into an ingot 16 by ¼ by ¼ inches. The pressure has been exerted on the sides of this ingot, not the ends. The ingot at this stage is too fragile to handle.

The slug next goes into an electric furnace where it is baked at about 2,400 degrees Fahrenheit. Now it is strong enough to handle. It is then sintered in a hydrogen atmosphere, the bar being heated for 10 to 15 minutes to about 5,000 Fahrenheit by the passage of an electric current through it.

The bar though brittle when cold is ready to be worked. It is heated to about 2,800 degrees Fahrenheit, and passed through the revolving dies of a swaging hammer which reduce its size and produce it in rods growing smaller and smaller and necessarily longer and longer as the metal goes through one swaging after another until it gets down to a diameter of three hundredths of an inch. It is now a metal that is ductile and its strength has increased with leaps and bounds so that at a diameter of three hundredths of an inch it can stand a pull in the proportion of 215,000 pounds per square inch of its diameter.

But it is still too large for lamp filaments, though wound on drums it appears hardly coarser than linen thread. So it starts into the process of being drawn down by successive stages through diamond dies of smaller and smaller sizes to any degree of fineness needed. On the drawing machines it unwinds from the feeding spool, passes through a lubricant, runs through a small gas furnace to attain red heat, negotiates the infinitesimal "eye" in the fragment of diamond clamped in its course, and is wound on a receiving spool ready for use.

Various of these fine sizes of tungsten wire are used for lamps of wide range of powers, the finest of them all being used for the tiniest of lamps such as "bug-lights" on automobiles and in flash lights. The diameter of this is 0.004 of an inch. It is six times finer than human hair. The original pressed ingot 16 inches long would produce more than 250 miles of such wire.

Tungsten wire thus produced is what has made the incandescent lamp the thing of power and service it is today.

The metal is worked in various other ways for its various other uses, but it never could have been had not Dr. Coolidge spent years in experimenting with it beyond the point where the scientists and metallurgists of the world had written the word "impossible."

### Gas-Filled Tungsten Lamp Patent Sustained

IN a carefully considered opinion written by Judge Hough, the U. S. Circuit Court of Appeals in New York, sustained on June 2nd, the Langmuir patent No. 1,180,159 for the Gas-Filled Tungsten Lamp. This lamp is the invention of Dr. Irving Langmuir, the well-known scientist in the Research Laboratory of the General Electric Company, which owns the patent.

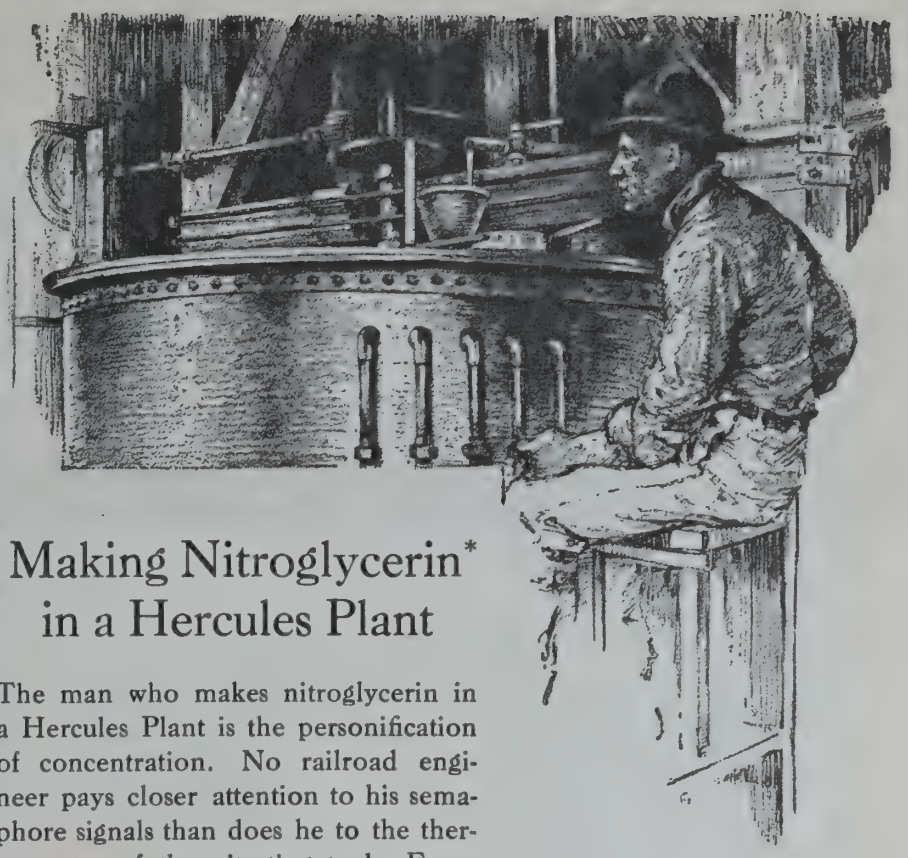
While several claims of the patent were in suit and sustained by the Court, the commercial nitro-tungsten lamp is well described in the following claim of the Langmuir patent, which is one of the claims held to be infringed by the defendant's lamp:

"An incandescent electric lamp having a filament of tungsten of large effective diameter and a bulb or globe therefor filled with dry nitrogen at a pressure as high or higher than that corresponding to 300 millimeters of mercury, the filament being thereby adapted for operation at a temperature higher than that which it would have if operated in a vacuum at an efficiency of one watt per candle."

The Court recognizes, as did the inventor, that a tungsten filament was not new with Langmuir, and that others, including Edison himself, had previously suggested the idea that a gas such as nitrogen might be introduced into a carbon filament incandescent lamp, but all such attempts to carry out that idea had been complete failures. Such suggestions the Court aptly characterizes as the history of "hopeful suggestion," and points to the fact that in 1913, when the Langmuir invention was made, so eminent an authority as Alexander Siemens regarded the vacuum tungsten lamp as the last word in glow-lamp lighting, without hope of any lamp improvement thereupon which might be of economic importance. The consequence of Edison's failure to find any utility in a gas-filled lamp was that lamp makers, the world over, remained convinced that the better the vacuum the better the lamp. Dr. Langmuir worked out his idea from the scientific standpoint, and the production of the gas-filled tungsten lamp was not only a scientific achievement but a revolutionary idea in practical lamp making.

After reviewing the technical theories advanced from time to time in regard to certain phenomena in incandescent lamps, the Court sums up its conclusions as follows:

"To us it seems fairly certain that both the commercial and the theoretic arts had been put on the wrong road by Mr. Edison through the disclosure of his patent No. 274,295 when in 1883 he proposed to fill a carbon filament bulb with an 'inert gas,' viz., nitrogen, at a pressure of about two-thirds of an atmosphere and stated as one of the means of his hoped for success that 'the filament before carbonization may be reduced to a *smaller* cross section than usual heretofore in order to produce reduction of radiating surface.' This was unquestionably wrong and we fail to find any suggestion in the evidence regarding the scientific discussion and theoretic statement that before Langmuir any scientist disclosed to the world that in the nitrogen filled bulb the loss by convection would be diminished and a working compromise reached between



## Making Nitroglycerin* in a Hercules Plant

The man who makes nitroglycerin in a Hercules Plant is the personification of concentration. No railroad engineer pays closer attention to his semaphore signals than does he to the thermometer of the nitrating tank. From the moment when he begins to feed glycerin into the acid in the tank until the operation is complete the thermometer is his guide.

It is important that the temperature of the mixture in the tank be kept uniform. If glycerin is added too rapidly the temperature rises, if too slowly it falls. So with eye on thermometer and hand on valve controlling the glycerin flow, the Hercules "N. G." maker follows the process minute by minute until its completion.

To just such watchful care as this is the uniform high quality of Hercules Explosives largely due. The men who work in the twelve Hercules plants realize the importance of the great tasks performed by Hercules explosives. As a result, wherever these explosives are used—in the building of railroads or highways, in the mining of metals and minerals, to increase the crops on a farm or dig the foundation for a city hotel—their giant power is never found lacking.

Hercules Explosives are always dependable—uniform in quality, high in power.

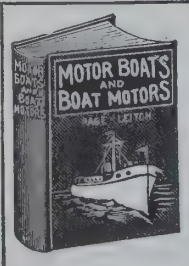
A New, Complete Book for Owners' Uses, Repairmen and Operators



## Motor Boats and Boat Motors

DESIGN—CONSTRUCTION—OPERATION—REPAIR

Written by a corps of experts, edited by VICTOR W. PAGÉ, M.E.

524 Pages (6x9), 372 Specially Made Engravings and Complete Working Drawings

Price, $4.00; by mail, $4.20

THIS is a complete handbook for all interested in any phase of motor boating, as it considers all details of modern hulls and marine motors deals exhaustively with boat design and construction, design and installation of all types of marine engines and gives expert advice on boat and engine maintenance and repair. Not only is boat construction fully treated but every needed dimension is given for building from complete, yet simple plans and construction is considered step by step. Everything from the selection of the lumber and laying out the boat molds to the finish of the completed craft is outlined in detail. The boats described have been built by the author and the plans are right. The book has also

A Special Chapter on Seaplanes and Flying Boats

SCIENTIFIC AMERICAN PUBLISHING CO., 233 Broadway, New York

that loss and the gain in filament life by increasing the 'effective size' of the filament itself.

"The patentee was also the first to establish another crucial and illuminating fact, viz., that with a tungsten filament, nitrogen of ordinary or commercial dryness was worse than useless. There is no evidence that any one before Langmuir had even suggested that in order to prevent a bulb-blackening fatal to the success of any lamp, the removal of water vapor not only from the gaseous filling but from the bulbs and filaments themselves must be carried to an extent theretofore unused, if not undreamed of.

"In short it was not through isolated experiments, but by correlating deductions from many of them, that the patentee produced in 1913 a lamp which, in the larger sizes, can operate on the usual 115-volt circuit with an efficiency as low as a half a watt per candle. . . . Not even the laboratory problem had been solved before this patentee did it; and we hold with the lower Court that invention was present."

While thus sustaining the patent on certain claims and against a specific construction found to infringe, the Court points out that the patent may possibly hereafter be construed to cover filaments other than tungsten and gaseous fillings not named in the specification of the patent.

### Right Foundation for Our Roads

THE United States Bureau of Public Roads and the Federal Highway Council are jointly conducting a national inquiry to obtain scientific information concerning the characteristics of road-building soils. The coöperation of thirteen highway district engineers has been obtained, 20 sample bags and tag envelopes having been supplied each engineer for shipping samples of highwav soil to Washington.

Road failures attributable to unstable foundations are possible of elimination by pursuing either of three alternatives: By having the road surface thick enough so that the pressure will be sufficiently distributed to the underlying subgrade or so that the surface due to inertia may absorb much of the shock of traffic; by designing the slab so as to insure adequate strength over the soft subgrade; or by improving the drainage systems to exclude the moisture in dangerous quantities from soils having very low bearing value due to the presence of water.

The nation-wide research as to the specific reasons for failures of highways involves the inspection of "break-downs" due to inferior subgrades, whether attributable to inadequate drainage or to peculiar soil conditions. Samples of one cubic foot each are taken from the subgrade, photographs made describing the failure, and exacting information furnished relating to topography, preferably in the form of cross-sections and profile of the road in the vicinity of the undermining influence. Notes are to be written describing the character of the failure, the approximate amount of traffic, drainage conditions, the presence of water-bearing strata or other influences that may be responsible for the wet condition of the subgrade.

An auger 1½ inches in diameter is suggested by the Bureau of Public Roads as a convenient instrument for exploring the underlying subgrade, useful information being obtainable by observing the texture and condition of moisture of the soil at varying depths. How the water reached the subgrade—whether by vertical or horizontal capillarity, through seepage strata, from the surface, etc.—is to be emphasized as essential data. If the soil at the surface is wet, very compact, dense and dry below, the chances are that the water penetrated the subgrade from the surface and was forestalled from release by the underlying impervious layer. If the underlying layer of a wet subgrade is moist and porous, and it in turn is underlain with compact pervious clay which is dry, the suggestion occurs that the porous layer is a seepage stratum through which water is flowing and is rising to the top of the subgrade by vertical capillarity.

"It is perhaps true that all soils have adequate bearing value when the amount of water in them is kept to a sufficiently low percentage," says the Bureau of Public Roads, "or it may be possible that certain soils will be susceptible of treatment which will render them of higher bearing value than they have in their natural state.

"It is obvious thati f we are to advance our ideas regarding road construction we must begin with the road foundation and must gain accurate information as to what properties of soils make them good or poor soils for foundation purposes. With this knowledge in hand, we will then be in a better position to say how the road should be designed when it is to be laid on these particular soils, or possibly how we should treat the soil when its characteristics are known in order to increase its bearing value."

### New Metal Alloy

DURING the war an Italian engineer, Adolfo Pouchain, after a series of experiments succeeded in producing a new alloy of zinc and copper, which has been given the name "Biakmetal." This alloy quickly demonstrated its usefulness in Italian industry, and by reason of its special qualities promises to attain similar success throughout the world. Biakmetal has aroused considerable interest in Italy, and we are told by one of the large manufacturers that his metallurgists have made every effort to determine its exact composition, but without success.

From a small beginning the demand for Biakmetal has increased to such an extent that a new company has been formed to carry on its manufacture. The industrial value of a product which is stronger than steel and less corrosive than copper is evident, and it is claimed that Biakmetal, which has passed the experimental stage, possesses these qualities. The most important characteristics are stated to be as follows: (1) The highest known breaking point; (2) the highest limit of elasticity; (3) perfect homogeneity; (4) high resistance to thermic action; and (5) high resistance to chemical action.

In the matter of strength, comparisons have been made between different grades of Biakmetal and copper, brass, and cannon bronze, which showed interesting results. Among these, tests were made of rods of various kinds of metal to determine the weight and size required to give a tensile strength of 500 kilos. The results of these tests were as follows (figures in parentheses represent the diameter of the rods tested, in millimeters, and the other figures, the weight of the rods in kilos per linear meter): Copper (12.6), 1.126; brass (9.5), 0.616; cannon bronze (10.3), 0.723; Biakmetal, No. 3 (6.3), 0.271; Biakmetal No. 6 (8.4), 0.178. (Millimeter, 0.0937 inch; meter, 39.37 inches; and kilo, 2.2046 pounds.)

These figures indicate a surprising superiority on the part of Biakmetal. Where Biakmetal No. 3 is used the same strength is obtained with a diameter and a weight considerably less than those of rods of other metals, while with rods of Biakmetal No. 6, of a diameter less than other metallic rods, the weight may be reduced to a small fraction of that of rods of other metals.

Biakmetal is extremely well adapted for almost any kind of manipulation. It can be successfully cast, turned, drawn, forged, rolled, and stamped. While its development is still in progress, it has already proved especially useful in aeronautic and marine construction on account of its light weight, its unusual strength, and its anticorrosive qualities. In its different forms it may be substituted for steel, brass, and aluminum, and for certain uses has important advantages over these metals.

Waterbury Button Co., Waterbury, Conn.

**INSYDE TYRES**
--genuine inner armor for auto tires. Double mileage; prevent punctures and blowouts. Easily applied without tools. Distributors wanted. Details free.
American Accessories Company Dept. 229 Cincinnati, Ohio

**ICE MACHINES** Corliss Engines, Brewers and Bottlers' Machinery
The VILTER MFG. CO.
899 Clinton Street Milwaukee, Wis.

*You can be quickly cured, if you*
**STAMMER**
Send 10 cents coin or stamps for 70-page book on Stammering and Stuttering, "Its Cause and Cure." It tells how I cured myself after stammering for 20 years.
Benjamin N. Bogue, 831 Bogue Building, Indianapolis

*Now Ready*
A New Book on a New Subject
**BEHIND THE MOTION-PICTURE SCREEN**
*By* AUSTIN C. LESCARBOURA

HERE, at last, is the wonder book of the screen. It takes the reader into that marvelous land where films are made, and where the camera reigns supreme. Every step in the making of a photo-play is taken up in proper turn, from the planning and writing of the scenario to the projecting of the finished film on the screen in the picture.

Talking pictures, natural-color pictures, microscopic pictures and all phases of the motion picture are treated upon in due turn. This book is printed on the highest grade coated paper. It contains 428 pages and over 300 illustrations. Bound in an attractive cloth cover. Size 6¼ x 9½. $3.50; postage—15c in the East, 20c to Chicago, 30c to the coast.

*One of the Most Attractive Books Ever Issued.*

Scientific American Publishing Co.
233 Broadway New York

# Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to Correspondents are printed from time to time and will be mailed on request. Please write your queries: do not telephone them, please.

(14337) The correspondent from 83 Cottage St., Lynn, Mass., is informed that his queries will be answered if he will repeat them signing his name to the letter. We do not answer anonymous letters.

(14338) A. M. asks: Can static electricity be changed to current electricity of low voltage, and how is it done? A. Whenever an electric spark passes across a gap static electricity is transformed into a current of electricity. But if you mean to transform such a discharge into a low voltage current for purposes such as are served by a battery, we should answer in general that such a transformation cannot be made.

(14339) O. C. S. asks: Can you suggest a simple method of testing ink for acid? A. The simplest way to test ink for acid would seem to be to drop into the ink some carbonate of soda (washing soda). Cooking soda (bicarbonate of soda) will answer the same purpose. If the ink is acid it will foam from the carbonic acid which is formed by the action of the acid upon the sodium salt. Probably also blue litmus paper may be used. The black of the ink would hardly stain the paper so much that the red from the acid could not be seen. An acid turns blue litmus red.

(14340) Chas. E. S. asks: I take the liberty of addressing you to ascertain if you know of any process by which the salt can be removed from salt water other than by steaming and condensing so that the water can be used free of salt at low cost. A. We know no way of removing the various salts from sea water in order to obtain fresh water for use, excepting by distilling the water. There are several chemical salts in sea water besides the common salt, which the chemist calls sodium chloride. All of these would not be removed by the same chemical process which would remove the common salt, while distillation will remove only the fresh water leaving all the salts behind.

(14341) F. H. R. says: I claim that anything which will sink in a tub of water will sink to the bottom of the ocean, vessels included. My friend argues that a vessel will sink to a depth of about 4,000 feet and there remain floating between the surface and the bottom. Will you please inform us who is right? Have you any publications for sale which covers this subject? A. Your inquiry has come to us very many times since the sinking of the Titanic and we have several times published the answer. The fiendish work of the submarine revived interest in the subject and now we have recently had a number of inquiries about the matter. Hence we will print the discussion of the topic again. Anything sinks in water when it weighs more than the same volume of water weighs. A cubic foot of fresh water weighs 62.4 lbs. Anything which weighs more than this per cubic foot will sink in fresh water. The density of sea water differs somewhat in different oceans and seas. It may be taken at about 1.03. At this figure a cubic foot of sea water would weigh about 64.27 lbs. Anything heavier than that per cubic foot will sink in sea water. Another most important factor is that water like all liquids is nearly incompressible. So incompressible is it that at the bottom of the deepest ocean, six miles below the surface the water is only 20 per cent heavier than at the surface, and a cubic foot of sea water at the bottom only weighs 77.12 lbs. Anything which weighs more than that per cubic foot will sink to the very bottom of the ocean in its deepest known place. Aluminum, the light metal, weighs 166.5 lbs. per cu. ft.; iron weighs 450 to 480 lbs. per cu. ft.; and stone weighs from 135 to 200 lbs. per cu. ft. Of course they go to the bottom anywhere when placed in water. There is a widespread impression that the tremendous pressure deep in the ocean will prevent sinking. Pressure has nothing to do with the case.

*SAFETY* perhaps is even more important than *mileage* to the tire user.

Yet, at a cost comparable with the prices of *ordinary* makes, Vacuum Cup Cord and Fabric Tires *combine the maximum* of skid-freedom and prolonged service.

***The Vacuum Cup Tread is GUARANTEED not to skid on wet, slippery pavements.***

Also, Pennsylvania Tires are *guaranteed*—per warranty tag attached to each casing—as follows:

| | |
|---|---|
| Vacuum Cup Fabric Tires | 6,000 Miles |
| Vacuum Cup Cord Tires | 9,000 Miles |
| Channel Tread Cord Tires | 9,000 Miles |

*Safety, mileage, service* and *price moderation* that typify the utmost in tire thrift and lasting satisfaction.

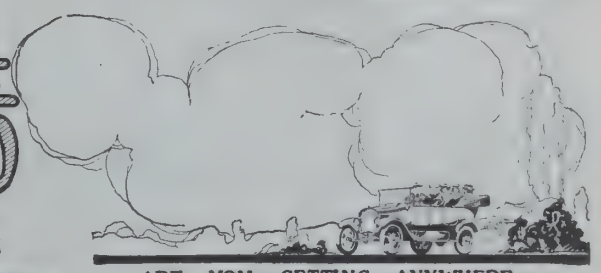
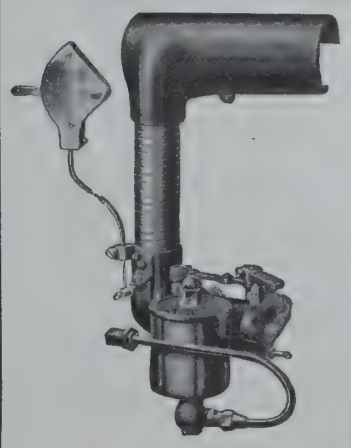
**37 4/10 MILES ON A GALLON OF GAS**



ARE YOU GETTING ANYWHERE NEAR THAT—FROM YOUR FORD?



Suppose you are getting twenty-two miles on a gallon of gas. Then, suppose you increased that mileage to THIRTY. There are eight miles of added travel—motoring that didn't cost you a red cent more than you are now paying—a reduction of approximately *thirty-three and one-third per cent.*

The New Stromberg Carburetor for Fords HAS caused just such astounding cost reductions for tens of thousands of Fords.

It established the World's official economy record. A mileage feat that has never been equalled—37 4/10 miles on a single gallon of gasoline.

Ready for immediate installation. Equipped with new improved easy starting attachment. Call on your local dealer or write us for descriptive matter. Beat the high cost of gas. Make your Ford a far more dependable and a far more economical car than ever before.

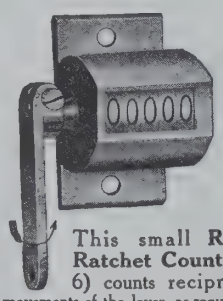
STROMBERG MOTOR DEVICES CO.
64 East 25th Street Dept. 816 Chicago, Ill.

New STROMBERG CARBURETOR Does it!

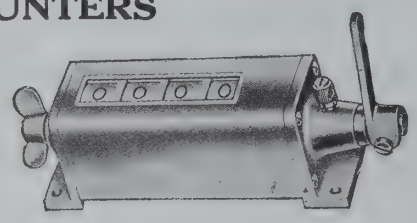
# Speed Up the Returns!

Make machines "pay back" sooner by cutting the time of production. Closer check-up on each operative's work will get *closer attention* to work, busier machines, better production-records. Keep track of results automatically *to-the-minute* with

Veeder
COUNTERS



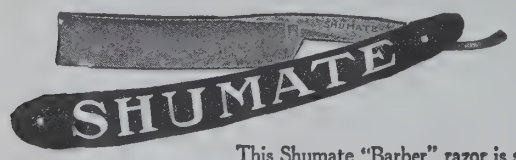
This small **Rotary Ratchet Counter** (No. 6) counts reciprocating movements of the lever, as required in recording the product of stamping presses. When the lever is moved through an angle of 40 to 60 degrees, the counter registers one. A complete revolution of the lever registers ten. This counter is adaptable to no end of small machines, simply by regulating the throw of the lever. Price, $2.00.
*(Cut nearly full-size)*



This large **Set-Back Rotary Ratchet Counter** records the output of punch presses, metal-stamping machines and others where a reciprocating movement indicates an operation. Registers one for each throw of the lever, and sets back to zero from any figure by turning knob once round. Provided with from four to ten figure-wheels, as required. Price with four figures, as illustrated, $11.50. (List.) Equipped with lock and keys to prevent tampering with the record, $2.00 extra.
*(Cut less than half size)*

*Wherever you've money invested in machines, Veeder Counters will promote quicker turnover. In our new counter booklet there's a model for every machine; may we send you free copy?*

The Veeder Mfg. Co., 18 Sargeant St. Hartford, Conn.



## You Take No Risk

**WRITTEN GUARANTEE**
**With Each Razor**

This Shumate "Barber" razor is so good that we dare guarantee it to you for *life*. Here's the reason—the blade is made from Tungsten Alloy Steel, which takes a keener edge than any ordinary steel *can*—and it holds it. You can use it for years without honing. The secret of this wonderful steel is *ours alone*, and we guard it jealously.

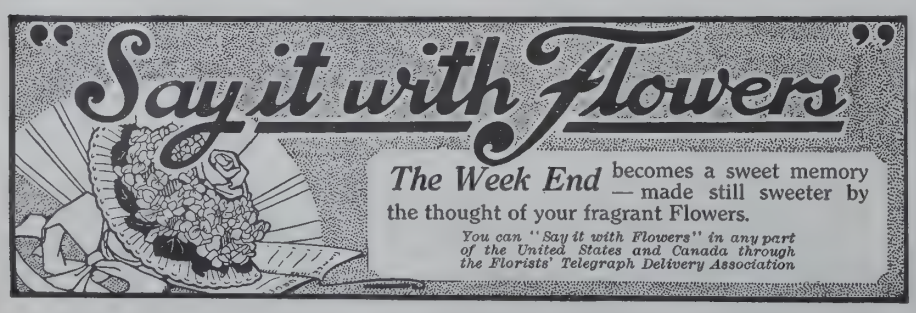
Here's our *unqualified guarantee:* Buy a Shumate "Barber" razor and use it—not once, but as long as you like. If you say after an exacting trial that you don't like it, we'll exchange it *without a word.*

$2. To settle the razor question for life, send us $2.00 and the SHUMATE Barber Razor will be sent to you post paid.

For those with very strong wiry beards, we recommend our $3.00 SHUMATE Razor, specially ground for this purpose. In remitting, give us your dealers name, and a chamois lined, rust-proof case will be included with your razor.

*Established 1884* SHUMATE RAZOR CO. *867 Chestnut St., ST. LOUIS, U. S. A.*

*Capacity 10,000 Razors Daily*



*The Week End* becomes a sweet memory — made still sweeter by the thought of your fragrant Flowers.

*You can "Say it with Flowers" in any part of the United States and Canada through the Florists' Telegraph Delivery Association*

The pressure of the air upon us is tremendous, more than a ton on every sq. ft., yet we fall swiftly through it simply because that pressure is the same on all sides of us, up, down and sideways. The same is true of water pressure. At any point the pressure is equal in all directions and does not retard sinking. An iron ship when filled with water goes swiftly to the bottom, as does anything which weighs more than the same volume of water. We do not know any book which treats the matter specifically. It is an application of the simple law of floating, Archimedes Principle, it is called in Physics.

## NEW BOOKS, ETC.

THE PETROLEUM HANDBOOK. By S. O. Andros, A.B., B.Sc., E.M. Chicago: Shaw Publishing Company. 12mo.; 206 pp.; 48 illustrations; 17 tables.

The many phases of the oil industry are all brought together here, and the fundamentals so concisely presented that the Handbook will appeal to producers, refiners, marketers, jobbers, salesmen, investigators, geologists, engineers and students. It describes all operations from the location of a well to the distribution of the refined products to the consumer, embodies pertinent facts culled from government bulletins and state reports, and forms a most satisfactory nucleus about which to build a library of more specialized works.

APPLIED OPTICS. The Computation of Optical Systems. 2 volumes. Translated and edited by James Weir French, B.Sc. London: Blackie and Son, Ltd., 1918. 8vo.; 377 pp.; illustrated.

The enhanced interest in optical glass in this country, due directly to the lessons of the war, makes a translation of the *Handbuch der Angewandten Optik* of Drs. Steinheil and Voit a valuable addition to the literature of the industry. Indeed, we believe this is the only published work giving a complete and thoroughly practical trigonometrical system of optical computation. The first volume deals with the principles of optics and the derivation of necessary formulae, the determination of simple lens forms, and the calculation of aberrations and combinations. The second volume includes the determination of refractive indexes and dispersions, the computation of achromatic prisms and of doublet objectives, and a dicussion of aberrations of different combinations.

FIRE DEPARTMENT MOTOR APPARATUS INSTRUCTION. By Capt. Daniel A. Sullivan. New York: Civil Service Chronicle. 8vo.; 95 pp.; illustrated.

There are thirty types of motor apparatus in use by the New York Fire Department; Capt. Sullivan, long instructor in the Department's automobile school, describes each type in "firemanic language," with lavish illustrations. Other chapters make clear gas engine parts and principles, the equipment of trucks and hose wagons, tools, lubrication and lubricating systems, ignition, and the theory of the dynamo. It is a complete and readily understandable text that will prove of the greatest service to students of fire department apparatus.

A TEXT-BOOK OF PHYSIOLOGY FOR MEDICAL STUDENTS AND PHYSICIANS. By William H. Howell, Ph.D., M.D., Sc.D. Philadelphia and London: W. B. Saunders Company, 1918. 8vo.; 1059 pp.; illustrated.

This standard work comes to us in a new edition that takes full account of the expansion of physiological and medical research in the past four years. In sifting the evidence for and against new theories, the author's stand is honest and impartial, and time and again he demonstrates his good judgment in stressing only what experiment and experience have sanctioned. In wending his way through the many difficulties that beset any presentation intended for the student rather than the specialist, he has made the path clear for the reader. Accepted fundamentals are vitalized by the new thought-current; the result, in Dr. Howell's skillful hands, is a text of the highest merit.

A HANDBOOK OF AMERICAN PRIVATE SCHOOLS. Boston: Porter E. Sargent, 1919. 8vo.; 761 pp.; illustrated.

The 1920 edition of this annual survey more than sustains its reputation for carefully-gleaned, comprehensive information such as the parent must have before he can choose wisely his child's educational environment. The work is more and more exceeding its original scope. Besides its critically descriptive lists of boys' and girls' schools and summer camps, which include art and trade schools and the private institutions of Canada, with location maps, we find much material of distinct service to school and college executives. There are sketches of history and progress, discussions of educational reconstruction, and a survey of the educational literature of the year past. Beginning with this edition, the handbook now covers not the calendar, but the academic year.

MANUAL OF SUGGESTIONS FOR TEACHERS. By Benjamin C. Gruenberg. Boston and New York: Ginn and Company, 1919. 12mo.; 95 pp.; illustrated.

The teacher who uses the author's "Elementary Biology" will find these suggestions extremely useful in organizing material and ideas, and in the effective presentation of the subject to their classes. It's interpretations, applications and references form a valuable supplement to the original text and to such material as the Department of Agriculture, the Public Health Service and the Bureau of Education issue from time to time.

THE PROTECTION OF METALS FROM OXIDATION AT HIGH TEMPERATURES. By W. E. Ruder. Vol. I. Detroit: Calorizing Corporation of America. 8vo.; 40 pp.; illustrated.

Protective coating processes and the development and application of calorizing are here set forth in brief but exceedingly helpful paragraphs. Leading manufacturers report their experiences with gas-making retorts. tubes and pipe, and the dependable tables offered may be advantageously used in various calculations and operations.

SELECTED ARTICLES ON PROBLEMS OF LABOR. Compiled and edited by Daniel Bloomfield. New York: The H. W. Wilson Company, 1920. 8vo.; 436 pp.

To the investigator of industrial movements and problems, this summary offers a quick way of familiarizing himself with outstanding features of the terrain, and its lengthy bibliography points the road to more thorough exploration. The work brings together in orderly from discussions of friction and unrest, methods of compensation, hours, tenure of employment, trade unionism, disputes and adjustment, limitation of output, industrial insurance, occupational hygiene, and women in industry. Varying points of view are presented, and the trend of the work is constructive.

SELECTED ARTICLES ON THE AMERICAN MERCHANT MARINE. Compiled by Edith M. Phelps. New York: The H. M. Wilson Company, 1920. 8vo.; 344 pp.

This work was first published in 1915 to arouse the interest and answer the questions of those who were following the fortunes of the bills providing for Government participation in the ownership and control of our merchant marine. This second edition adds much material setting forth the situation developed since the creation of the Shipping Board, and takes up the disposal of the fleet. From historical facts to present conditions, the student will find all important questions debated from various points of view by well-qualified disputants. The arguments are preceded by briefs, and there is a good bibliography.

KEY TO THE BIBLE AND HEAVEN. By Ludwig B. Larsen. Portland, Oregon: Ludwig B. Larsen. 8vo.; 280 pp.; illustrated.

The writer regards the Bible as a treasury of astronomical, astrological, and geographical information, and interprets its symbolism in accordance with this belief.

"PRACTICAL ENGINEER" MECHANICAL POCKET BOOK AND DIARY. 1920. London: The Technical Publishing Co., Ltd. 800 pp.; illustrated.

For thirty-two years this British pocket book has catered to the needs of the profession. Data of steam, gas, and oil engines, air compressors, heating and ventilation, hydraulics, etc., are supplied in concise form; in material new to this issue we find information on boiler chimneys, steel stacks, chains and pyrometers. The Buyers' Guide, in French, Spanish and Russian, continues to be a prominent feature.

INTERNAL-COMBUSTION ENGINES. By Wallace L. Lind, Lieutenant Commander, U. S. N. New York: Ginn and Company, 1920. 8vo.; 225 pp.; illustrated.

Lieutenant Commander Lind's text is crisp and business-like in its phrasing, and will be found well-adapted to the average student. One chapter, addressed to readers familiar with thermodynamics, presents the theory of the various cycles. Besides the usual considerations of fuels, combustion, carburetion, etc., there are discussions of the regulation of speed and power, the measurement of power, and the principal enpgine parts and their functions. Aircraft, marine, and automobile types are described, with the cause effect and remedy of troubles.

# Where 48-10 Air Hose is Supreme

In shipbuilding yards air hose gets its hardest test. Bent over the sharp edges of steel plates, stepped on, run over, burnt by hot rivets —ordinary air hose does not last long under these conditions

It is different with 48-10 Air Hose. On March 3d a hundred foot length of 48-10 Air Hose was installed as a section in an air line several hundred feet long. On June 23d it was still in good condition, while twelve fifty-foot lengths of ordinary air hose on this particular line had been replaced.

48-10 Air Hose has an extremely tough cover. It is provided with a special tube which the oil from the compressor does not effect. It is light and flexible. Costs more than other air hose, but it lasts a great deal longer.

# Could *You* See in a Fog?

Poor light in a factory where the eye must guide the hand is like groping in semi-darkness. It means danger, delay and spoiled merchandise.

Poor light puts a partial blindfold upon your most skilled machine operator; he becomes a danger spot to himself, his co-workers and the material he is working on. Multiply this by the total number of workers and the answer is truly startling.

It is possible, of course, to work under inadequate light, but not efficiently. The cost to you of poor light as determined by careful tests is 12% *less* production, 25% *more* spoilage and 25% *more* accidents. Can you afford to pay this price for poor lighting? Think it over.

Call upon your engineer, contractor or architect to design an efficient lighting plan for you. Our own Illuminating Engineers will gladly work with them and assist in the selection of correct reflectors that will secure for you maximum lighting efficiency.

**Some idea of the magnitude of our cereal harvest may be gathered from these graphic comparisons showing the crop for 1918 and that for 1869**

## If Our Cereal Harvest Should Descend on New York City

THERE are several cereals such as corn, wheat, oats, etc., and if the total amount of all cereals harvested in the United States should fall suddenly, like a heavy rain, upon New York City, such a cereal deluge would cover the metropolis to a depth approximating 9 6/10 inches. This does not seem very much cereal, but were it to be placed upon Madison Square it would then approximate a height of more than 4 miles! And, further, were all this cereal harvested in the United States to be placed in Madison Square upon a base having an area of 100 square feet, that is, a base 10 feet long by 10 feet wide, and then to be toppled over, it would fall, were it to be solid like stone, to a distance equal to about that of 5 times to San Francisco. Or, in other words, one year's cereal harvest in our country would, on a base containing an acre of land, rise to approximately the same height as would 214 Woolworth Buildings, placed one upon another.

Moreover, this annual cereal harvest would fill a street 100 feet wide running from the Battery to 44th Street to a height of about 3,315 feet; or a street 200 feet wide running from the Battery to near the city line to a height of about 432 feet; or a street 1,000 feet wide from the Battery to the City Hall to more than 1/3 of a mile. It would bury Union Square to a depth of 750 feet and there would be enough left of our country's harvest to bury City Hall Park under almost 4 miles of cereals. If our national cereal harvest should descend wholly upon Central Park it would bury that park to a depth of approximately 190 feet. And if this storm of cereals should descend upon New York City at the rate of one million bushels a day it would not cease falling upon that city for 19 years, that is, it would fall without stopping from 1919 till 1938. The accompanying graphic comparison, showing our cereal crop for 1918 and that for 1869, speaks for itself. It tells the story of our production.—By *Charles Nevers Holmes.*

## Phosphoric Acid and Potash Now Produced

ALMOST unusual and novel application of electricity has recently been introduced commercially. It is the direct result of experience gained during the war and is a new use of electric furnaces regularly employed in metallurgical operations.

There are two types of electric furnaces used in the steel industry—one is the regular melting or refining furnace for making steel; the other is the shaft furnace in which most of the ferroalloys are made. A southern ferroalloy company, which, during the war made ferromanganese and several other alloys, found itself confronted with severe competition after the armistice and with the problem of finding a profitable use for its expensive equipment. The result of extensive investigations has been the following unique use of these furnaces.

The new departure involves the manufacture of phosphoric acid and of potash. The former has been made and is now being made by chemical processes on a large scale. Its electrical production is new, especially by the means referred to. Phosphate rock is put in the shaft electric furnace and smelted or disintegrated by the electric cement. Phosphoric oxide or $P_2O_5$ is formed, which passes off as a gas or in the gases. These are collected in chambers, and electric currents of high power are passed through the gases from which the phosphoric acid is precipitated as a powder. This is an application of the Cottrell electric precipitation method recently described in these columns. In this manner an unusually commercially-pure product is obtained free from many of the impurities introduced when sulfuric acid is the disintegrating medium acting on the rock instead of electricity. This product is further treated and concentrated.

In the case of potash the shale rocks of the Southern States, which are high in potassium compound, are introduced into the same kind of furnace and treated similarly. The product of this electrical disintegration is potassium oxide or potash, $K_2O$, which is also precipitated electrically from the gases which are evolved. Both of these products are valuable as fertilizers and the use of this process has a bright future.

The use of electricity in these two interesting cases instead of expensive chemicals is not only a feature of this new departure but there is the other novelty that electricity is used both as the destroying or breaking-down agent and as the medium by which the final products are recovered.

## Hawaiian Motors Run on Molasses

FROM the lowly and sticky molasses is being produced "motor alcohol"—a substitute for gasoline. Discovered by J. P. Foster, chemist of one of the big sugar plantations on the Island of Maui, Hawaii, production within the next three months will be sufficient to furnish fuel for all cars on the islands should a gasoline shortage occur. According to the first reports of the new fuel brought to San Francisco "motor alcohol" gives more power, greater mileage, easier starting and more freedom from carbon than gasoline. It can be used without an adjustment of the carburetor.

The new fuel is performing in automobile, marine, stationary, truck and tractor engines. In a 36-hour test made with a 75-horse-power tractor the consumption of "motor alcohol" was four gallons an hour compared to four and a half gallons of gasoline in the same engine on the same work. Examination of the cylinders showed most of the old carbon deposit removed and the remainder so soft it could be removed with the fingers.

Sugar plantations have been letting their molasses run to waste or burning it for the potash recovery. Nitrogen and phosphoric acid are also valuable by-products of molasses. Now, however, production of the new fuel is found to be more profitable than obtaining other by-products.

At present there is enough molasses available to produce 9,000,000 gallons of "motor alcohol"—enough to supply all automobiles in Hawaii. Development of this industry will release shipping space formerly used for transporting gasoline from the United States.

## A Prediction and Its Fulfilment

WE offer no apologies for republishing in this issue an article which was written ten years ago in a special aviation issue of the SCIENTIFIC AMERICAN that was brought out during the famous aviation meet at Belmont Park, in October, 1910. That meet was memorable because for the first time America was afforded an opportunity to see the very latest developments in aviation; for the best machines and the most noted fliers, both here and in Europe, were gathered at Belmont Park. Records were broken; and both as to speed of machines and skill of pilots, the gathering was literally, at that date, the last word in aviation.

The article was written without any wish to depreciate the skill either of the builders of the airplanes or of the pilots who flew them. Rather, it was stimulated by the conviction that the airplane development of that day was too much in the hands of the amateur, and, as invariably happens in such a case, successive machines too closely followed the lines of previous development. The writer felt satisfied that when the scientist and the practical engineer, as represented by Langley and Manly of the Potomac experiments, took up the work of development in good earnest, there would be a radical change from the curious and complicated constructions which prevailed at Belmont Park, with their multiplication of struts, ties, braces and other energy-consuming surfaces, and the airplane would be brought to its ultimate bird-like shape and fabricated in the wonderful constructional alloy steels which even in that day were available.

It is with a very natural satisfaction that we have witnessed the appearance, first in Germany, and later in this country, of the all-metal monoplane with its corrugated wing surfaces and its freedom from external struts and ties. The folding chassis as we then called it, retractable chassis as it is now known, has come into its own. Gyroscopic control of the ailerons as then predicted has been developed in practical form, and streamlining, as indicated in those early sketches, is now a *sine qua non* of all good airplane design.

By analogy, it is probable that the monoplane will be restricted to the smaller and medium sizes of machines. Plate girders can be used in railroad bridges only up to a certain length of span; above that length, the economics of construction call for the truss. So it will probably be found that although the monoplane is ideal for the smaller machines, the trussed biplane or triplane will be necessary when the wing span and the weights exceed certain figures.

If the development of the past decade has brought us to the stage of the perfectly streamlined metal monoplane, what will be the development of the next decade? We do not hesitate to predict that there will be more attention directed to the motive power and the propeller than to any other elements of the airplane. The internal combustion engine, even in such highly efficient and reliable types as the Rolls-Royce, the Liberty and the Hispano-Suiza, is far from being an ideal airplane drive. It is noisy beyond all endurance, and in spite of the reliability shown in some of the recent flights, it does not possess the rugged durability and the absolute dependability which are demanded for a machine which becomes a comparatively inert mass the moment its engine ceases to function. For this reason, we believe that aeronautical engineers will turn their attention increasingly to that well-tried prime mover, the steam engine. With this will be coupled some type of feathering reversible propeller, which will be equally efficient at all altitudes, and will provide that powerful braking action, which is necessary to make the landing of an airplane as safe as its taking off.

## Hudson River Bridge as a War Memorial

AS far back as the days of those master builders, the Romans, it was recognized that there was an inherent dignity and permanence in a bridge of proportions, which rendered it admirably adapted to serve as a memorial to great national achievements. An added fitness for memorial purposes is found in the fortuitous fact that the engineering requirements of bridge construction call for a distribution of materials which lends itself to great beauty of line and an impressive grouping of mass proportions. And not alone in the ancient world and in mediaeval times, but in our modern age of steel the bridge has held its place as a worthy form of memorial; some of the finest crossings of the great rivers of Europe having been dignified in this way. It was altogether natural therefore that the Mayor's Committee on Permanent Memorial should have voted by a large majority in favor of making the great bridge which is to be built across the Hudson, a memorial to the soldiers of New York who took part in the World War.

Even if bridge memorials did not have the sanction of the centuries, the selection of the Hudson River bridge must necessarily appeal to our imagination and to our general sense of the fitness of things. As the recent conflict was the greatest war in all history and our share in it was the supreme military effort of this country, it is fitting that this structure, which will be beyond all comparison the greatest single feat of engineering in this age of steel, should receive the added dignity of serving as a permanent national memorial. Architecturally it will meet every requirement of impressive magnitude, classic beauty, and assured permanence. Its great central span of 3,200 feet is just twice the length of the Brooklyn bridge, measured from tower to tower. Spanning as it does the noble river which, more than any other, is associated with the early history of the country, and looking down upon the river front from which our soldiers set out for the battlefields of Europe, it will be most aptly situated to fulfil the demands both of history and sentiment.

And it so happens that the masonry anchorages, which in a bridge of this size are necessarily of enormous proportions, lend themselves with peculiar facility to architectural and structural treatment of a memorial character. The anchorages which form the portals of the bridge will be masses of granite masonry, 220 feet in width, 340 feet in length, and over 200 feet in height. The upper deck of the bridge will contain in the center of its 200 feet of floor width a boulevard 80 feet wide, and entrance to the bridge will be made through three great arches in each anchorage —a central arch 100 feet wide, with side arches of half these dimensions, all three of these being executed in sculptural stone. After passing through these arches, there will be visible the four steel cables, each eight feet in diameter and covered with bronze plating, which will sweep in great curves to the top of four towers, each 650 feet in height. Although these towers will be built of structural steel, the steel work will not be visible, since they will be clothed from water level through the whole up-curving sweep of them with gray granite, each tower forming a tapering octagonal shaft, second only in height to the Woolworth tower, and many feet loftier than the Singer tower. The group of four towers will be pierced with three arches, granite or marble covered, of noble proportions, through which entrance will be had to the main span with its vast sweep across the river of 3,200 feet. The approaches from the Jersey side will be similar. It can readily be seen that the vast masonry surfaces will suffice for a display of sculptured emblematic and memorial work and bronze tablets on a scale commensurate with the dignity of the subject.

The designer of the Hudson River bridge, Gustav Lindenthal, wishes it to be clearly understood that the bridge as an engineering proposition will be built with private capital, and that the cost of the memorial features, only, will be borne by the city.

## Is Naval Design in the Flux?

ARE naval design, construction, strategy and all the rest of it in a state of flux? When Beatty led the German fleet into contact with the British, Jellicoe, with twenty-five battleships, had the speed and power to close in and absolutely annihilate the Germans. Why did he not do so? Because of his very proper fear of the torpedo. He escaped torpedo damage by keeping the German destroyers at such a distance that their torpedoes were discharged haphazardly, lost their speed before they reached the British line, and were easily avoided by maneuvering.

Have you ever considered that the gas engine is liable to upset many of the theories and practices of naval construction and warfare? It is a thought well worth consideration, and we invite attention to it just now.

Is it not rather strange that the British should have scrapped half their battleship fleet and stopped all battleship construction? And that they should so complacently sit down and watch another navy spending seven hundred and fifty million dollars on eighteen battleships and battle-cruisers which, theoretically, when completed, will wrest from her that protective supremacy at sea which she has always believed, and still believes, to be necessary to the security of her far-flung empire? Why this complacency? If you asked Admiral Benson, he would probably answer "They are hard up. It is necessity." But can we be so sure of this? Is it not possible that their vast war experience showed the British that the terrific punishing-power of the torpedo, due to new methods of bringing it within point-blank range of the enemy, demands a radical revision of some of our fundamental war concepts?

We believe that in future war the torpedo will at last come into its own, and it will be the internal combustion engine that will work the change. It gave us the motor car and the airplane, and now it is perhaps destined to dethrone the battleship and battle-cruiser as the supreme elements of naval strength. But how? Well, the British have several large and fast torpedo-plane carriers. Let us forecast a duel between a twelve-gun, 23-knot "Massachusetts," and a 32-knot torpedo-plane carrier, with twice that number of planes aboard. Steaming outside of 16-inch gun range, the carrier would send in her planes which, swooping down from great height at 150 miles an hour, would drop their torpedoes within close range and return for more. But the bulge will save the ship? No; for the torpedoes will be set to pass underneath the ship and they will be fired magnetically by the action of the steel mass of the ship itself. And you could not put side and bottom bulges, both, upon a ship—she would be all bulge and but little ship.

Again, the internal combustion engine has opened up another form of attack in the shape of the so-called one-man torpedo boat—a type which is coming along very fast. It begins to look as though the gas-driven, high speed, motor boat, carrying its torpedo discharge below water, would fulfil the functions in which the torpedo boat failed utterly and the destroyer partially. It has the torpedo efficiency of the destroyer without its size and visibility. To hit, the torpedo must be fired at close range—the Germans found that out at Jutland. The torpedo motor boat is so small a mark that it can dash in at thirty knots to within point-blank range without the anti-torpedo gunner being able to draw a bead upon it, so rapid is the change of range; and twenty sea-going motor boats can be sent in for the cost of one destroyer.

Seaworthiness? Well, they are growing in size, and the latest type would have no difficulty in keeping station as part of a fleet organization.

There are evidences, clear to the close student of naval development, that naval theory, construction, strategy and tactics are very much in the flux just now, or soon will be.

## Electricity

**Collapsible Tool Bag for Linemen.**—There has recently been placed on the market a canvas tool bag for use in hoisting tools, paint and other implements or supplies by linemen. The bag is made with no metal parts that can come in contact with the current, as the sides are of canvas, the bottom is of wood, and the handle is of rope. The manufacturers have designed it to hold tools and materials which, if not properly taken care of, may be a menace to those below.

**An Electric Pipe Thawer.**—It is hardly seasonable to be speaking of pipe thawers; but winter must come sooner or later and pipe thawers are equipment which cannot be left to the last moment. There has been placed on the market a pipe thawer in a highly portable form. It consists essentially of a transformer, consuming ordinarily about 550 watts, a 10-foot lead for connection to the lighting circuit, and secondary leads equipped with cast-brass clamps for attaching to pipes from ½ to 1 inch diameter. Alternating current of 50 cycle to 60 cycle frequency and 100 to 125 volts is used. The spread of the secondary is 15 feet.

**The Sheringham Daylight Lamp.**—Owing to the variable intensity and color of daylight, according to season and climatic conditions, an artificial illuminant giving light equivalent to that from a diffused north sky would be of great value in many color-matching operations. In the Sheringham device a glow-lamp (or other illuminant) is placed under a large shade the inner surface of which is covered by a special design in colors. The lower half of the lamp is screened by a reflector which directs light upward on to the mosaic of colors, whence it is diffusely reflected. The colors can be so selected that the reflected light closely resembles diffused north skylight, light from a blue sky, or sunlight. A diagram is given showing the spectrum distribution of light from a blue sky, noon sunlight, a tungsten lamp, and the artificial daylight produced by the Sheringham lamp. The efficiency of the unit is stated to compare favorably with that obtainable from previous methods of producing artificial daylight.

**Intensity of Wireless Signals.**—A method of measuring and comparing the intensities of signals received by a radio station has been worked out in France with good results. This method, which can be employed only for undamped waves, essentially consists in comparing the intensities of reception of the signal and of the sound produced by a local source of oscillations, of the same frequency and form, constituted by an ordinary heterodyne. By modifying the intensity of the action of the auxiliary oscillation-generating device upon, say, the antenna, a rough equalization is first obtained, afterwards, by maneuvering convenient shunts to the telephone an absolute equality of intensities is obtained. The ratio of intensities is proportional to the shunt resistances. Moreover, by inserting a thermo-galvanometer in the antenna the absolute value of the intensity of the auxiliary signals can be obtained. The error in the practical use of this method is from 5 to 10 per cent.

**France's Wireless Plans.**—A dispatch from Paris states that the French Government has recently announced plans for an elaborate wireless system whose center will be in Paris and which will cover Europe, Asia, Africa and South America and connect with North America. If this system, part of which is already in existence, is integrally applied as now proposed, France's wireless communications throughout the world will be able to rival with Great Britain's cable communications. According to the details made public at a recent meeting at Rennes, wireless communication was established with Hungary May 20, 1920, and will soon be opened with Belgrade. For commercial communication with the United States there is a station at Doua, near Lyons, in addition to the Lafayette station near Bordeaux. Between France and its colonies there will be stations with a range of 7,500 miles at Saïgon and at Tahiti. Stations with a radius of at least 4,375 miles will be established at Djibouti, Tananarivo, Noumea, and French Guinea. In Africa the system will include stations at Saida and Bamako, which will take care of the traffic between Paris, Algeria and West Africa; another station in Senegal, near Dakar, and finally that of Brazzaville.

## Science

**Collection of Aeronautical Instruments.**—The official collection of aeronautical instruments maintained by the Bureau of Standards in Washington is said to be one of the most comprehensive in the world. It includes instruments of French, German, British, Italian, Russian, Swiss, Danish, Dutch and Austrian manufacture as well as those made in America.

**Biochemical Research at Cambridge.**—The University of Cambridge has received from the estate of the late Sir William Dunn a large fund to be used in endowing biochemical research and instruction at the university. A minimum total expenditure of $825,000 is contemplated for the erection and equipment of buildings and the endowment of a professorship and a lectureship.

**Marine Laboratory in Hawaii.**—The University of Hawaii has received a fund from the C. M. Cooke estate which is to be used in establishing a marine biological laboratory in connection with the Honolulu Aquarium at Waikiki now under the supervision of the university. Facilities will be provided for work by visiting scientific men. Biologists who wish to use the laboratory should communicate with Prof. C. H. Edmondson, the director.

**The Mango in Florida.**—The U. S. Department of Agriculture has secured through its agricultural explorers and by exchange with the British East Indian departments of agriculture one of the largest collection of mango varieties in the world, and now has in fruit, at its plant introduction station at Miami, Fla., about 20 varieties, selected from a much larger number. It is said that these selected varieties strikingly belie the many unkind things that have been said about the mango and that are really applicable only to the inferior sorts. Some of them have hardly more fiber in them than a freestone peach, and can be cut open lengthwise and eaten as easily with a spoon as a cantaloupe. They have a delicious odor, suggestive of pineapples. The mango is destined to become one of the important products of southern Florida, south of the line of heavy freezes.

**The Reappearance of Minerva.**—The 1920 issue of the *Minerva Jahrbuch der gelehrten Welt* has recently appeared, this being the first issue since that for 1913-14. It was expected that this unique international directory of scientific establishments and their staffs might be made superfluous by the publication of the new French *Index Generalis*, but as the latter (judging at least from the initial volume) is only a directory of educational establishments, the two works do not cover identical ground. The latest *Minerva* is extremely incomplete for many countries, and for obvious reasons, but contains addresses and statistics not available from other publications pertaining to the scientific establishments of Germany, Austria and Hungary, besides much information relating to Switzerland, Denmark, Sweden, Norway, Holland, Bulgaria, Esthonia, Czecho-Slovakia and a few other parts of the world. *Minerva* is now published in Berlin and Leipzig, instead of Strassburg.

**Rasmussen's Studies of Eskimos.**—The remarkable studies carried out by the Danish explorer, Knud Rasmussen, among the Greenland Eskimos are described by Mr. W. E. Ekblaw in the *Geographical Review*. Rasmussen, who is part Eskimo himself, was born and partly educated in Greenland and trained in languages and ethnology at the University of Copenhagen. It is his ambition to make a thorough study of the whole Eskimo race, from eastern Greenland to Siberia, and he has already visited every Eskimo settlement in Greenland. It is said that he knows every Greenland Eskimo personally. Mr. Ekblaw believes it safe to say that no one else has ever come into such direct contact with a whole people as he has. Late in 1919 he returned from a visit to Ammassalik, on the east coast. He was surprised to find that the East Greenland Eskimos preserve many of the customs of the Central Eskimos, who still inhabit the ancestral home of the race about Hudson Bay. He found that they are more closely related to the Central Eskimos than are any of the other tribes of the entire Greenland coast, and that only recently have they been affected by contact with the Greenland west coast culture.

## Industrial Efficiency

**Tanned Sponges.**—An interesting process has recently been developed for increasing the efficiency and extending the life of sponges used for technical purposes, automobile washing, office use, etc.—in fact for all purposes except use on the human anatomy. It consists in a modified tanning process, and it makes the sponge take the water much better and act more satisfactorily in giving it up to the work.

**Our Business in India.**—With the United States and Japan each maintaining advantageous business in India and British manufacturers endeavoring to regain their pre-war position in this market, competition is keen for the trade of that country, accordng to the *Trans-Pacific*. Textiles and machinery mainly from England, cotton hosiery, silk piece goods, and glassware chiefly from Japan, and electrical machinery and automobiles almost entirely from the United States, supply India's demands in these lines at present. The importation of paper from the United States during the last year greatly increased, and American manufacturers successfully furnished the Indian market with supplies of hardware, bolts and nuts, nails, rivets and machinery and mill furnishings generally.

**New Uses for Stainless Steel.**—Since the Armistice there has been an enormous sale of stainless steel for cutlery purposes. The demand is increasing, and the labor and machinery in the Sheffield cutlery trade are inadequate to deal with the influx of orders. Stainless steel is being employed very largely in the manufacture of pump rods, valve spindles, valves and other parts which are exposed to contact with water, steam and other corrosives. The scientific instrument trade is using it for drawing instruments and other precision tools and for surgical instruments. It is being manufactured into stair rods, saucepans, and pans of varying shapes, fenders for the hearth, and even into pokers and garden implements; and butchers' rails, spikes, skewers, saws, and other butcher-shop requirements are being made from it. Stainless steel is also being used for golf-club heads, spurs, etc.

**Long-Distance Rafting.**—Swedish lumbermen are on this coast investigating the possibility of rafting lumber from British Columbia to Europe. Lumber rafts of large size, called rafanutes, have been successfully towed from Sweden to Great Britain. The Ocean Rafanute Syndicate, of London, England, has sent William Olsson, of Stockholm, an experienced rafanute builder here, to investigate the possibility of adapting that method to British Columbia timber exports. The rafanutes are made of squared timbers. Mr. Olsson, though expressing nothing definite, believes that the tremendous timbers of the British Columbia forests will make possible the construction and successful operation of rafanutes far larger than the rafts now shipped out of the Baltic. Swedish structures carry four or five million feet each. It is proposed that the British Columbia rafts will contain fifteen to twenty million feet.

**Wanted: New Uses for Rubber.**—The Rubber Growers' Association of London is offering certain sums of money, as below, for ideas and suggestions for extending the present uses or for encouraging new uses of rubber. The awards consist of: First, £5,000; second, three prizes of £500 each; third, ten prizes of £100 each, and a sum not exceeding £1,500 to be divided among the remaining competitors whose suggestions are considered to be of value, according to the relative value of their suggestions, but so that no competitor will receive more than £100. The association points out that "suggestions must be practical and likely to increase the demand for the raw material. Ideas will be welcomed for the application in new directions of existing processes, methods, or manufactures, or for improvements or new processes which will facilitate or cheapen the production of rubber goods. Competent judges (technical and otherwise) will be appointed to investigate and adjudicate upon the suggestions received." The latest date for receiving suggestions is December 31st, 1920, and no envelopes containing the same will be opened before that time. Full particulars of the conditions governing this competition can be obtained from the Rubber Growers' Association, 38 Eastcheap, London, E. C., 3. England.

# Reducing Trade Routes with Submarine Freighters

## How a Special Type of Submarine Might Be Employed for Traversing the Arctic Ice Fields

By Robert G. Skerrett

THE Northeast and the Northwest Passages, with their strong appeal to the venturesome navigators of other days, are likely to be turned to thoroughly practical commercial account in the near future, thanks to potential developments in the realm of under-water travel.

In the course of the last five years the submarine evolved from a coastal or harbor defense craft into a vessel capable of taking to the high seas and holding her own in the open ocean for weeks' running. But probably no phase of this department of naval architecture has been more suggestive than that typified by the German subaqueous freighter "Deutschland" of something like 1,700 tons. Simply because she was the lone example of her class to reach our shores and to win any considerable notoriety, little heed has been given to the significance of her performances.

Simon Lake, however, is thoroughly convinced that the cargo-carrying submarine has a conspicuous and a valuable part to play in peace-time trade; and he has brought his wide experience in subsurface navigation to bear in designing a submergible freighter especially suited to following routes normally considered closed to the average merchant steamer. In these days when labor is high; when the world cries aloud for an abundance of raw materials; and when time, indeed, means money, any agency which will shorten the journey of essential commodities, will abridge the transit period, and, in effect, bring widely separated points on the globe much nearer together, will prove a veritable boon.

Despite the fact that Sir Robert McClure, during his expedition of 1850-54, proved that ships might pass from the Atlantic into the Pacific by threading the Arctic waters washing the northermost shores of North America, and that Nordenskjold, in 1878-79 was able to complete a kindred voyage along the frigid coasts of Europe and Asia thence to the Pacific Ocean, nothing more than scientific interest has since been centered in these regions mainly because barriers of ice interpose more or less at all seasons to make progress there too hazardous, tedious, and uncertain for the bustling craft of commerce bent upon reaching her destination with dispatch. Further, marine underwriters, knowing the risks to be run, would not have insured either the vessel or her cargo. Therefore, oversea traffic has followed for generations longer and, withal, safer routes. But what has been done in the past is not necessarily a conclusive guide for the future, and Simon Lake proposes taking advantage of those northern waterways which have heretofore excluded the average mariner.

True, the longest way round is at times the shortest, allowing for circumstances that otherwise might occasion delay. Let us see what this actually means so far as separating distances are concerned. Suppose, for example, that the object is to carry goods from New York to Cape Nome, Alaska, and then to bring back a return load to the American Metropolis. The trip, outbound, via the Panama Canal, would mean a voyage of 7,945 nautical miles. To reach the same Alaskan port by way of the Arctic Ocean—entering the Pacific by Bering Strait—the run would be 6,660 knots, a difference of 1,285 miles, or 2,570 knots in a round trip. Again, imagine a steamer bound from Liverpool to Nome. Today, if she goes through the Mediterranean, using the Suez Canal to reach the Indian Ocean, and thence into the Pacific and northward off the eastern shore of Asia to Alaska, she must trace a route 13,705 miles long, whereas 9,280 miles might be saved on a single run if she could make the voyage through the Arctic Ocean! Of course, the journey could be shortened 1,715 miles by crossing the Atlantic, using the Panama Canal and thence up the west coast of North America, but this would still be 7,565 miles more of a run than the route through the northern waters. It calls for no stretch of the imagination to visualize the time and the money that might be saved by abandoning the established lanes of deep-sea transportation.

The practicability of the northern route is founded upon data furnished by well-known Arctic explorers and upon Mr. Lake's own experience some years ago with a submarine torpedo boat which he sold to the then Imperial Government of Russia. During the severe winter of 1903-04, the craft in question was operated in Narragansett Bay, and on several occasions she was run beneath heavy floes of ice. To facilitate maneuvering of this sort, the submarine was equipped with an overhead skid or guard which made it an easy matter for her to skate, so to speak, on the nether surface of the overlying ice.

According to information furnished Mr. Lake by such men as Scott, Nansen and Steffanson, and confirmed by Nansen in his well-known book, it seems that ice in the Arctic Ocean does not exceed a vertical thickness of more than 14 feet in the winter season, and fields of ice are never more than 25 miles across before there occurs a stretch of open water. In the summertime it has been the watery breaks and the presence of slush ice which have hampered the Arctic traveler—neither walking nor paddling being possible except under extreme difficulties. These are the physical conditions which Mr. Lake counts upon turning to his advantage. His intention is to operate his submarine cargo carriers in the summer months when the ice has broken up and become more or less rotten. It is said that icebergs do not prevail in that area of the Arctic Ocean contiguous to Siberia and North America and they probably would occasion trouble only when traversing Baffin Bay and the approaches to Hudson Bay. These, of course, would be seen and avoided while at the surface. The purpose of the submarine is to under-run ice jams, wide and solid floes, and not to dive beneath bergs.

The submersible freighter planned by Mr. Lake would have an overall length of 395 feet, a molded beam of 45 feet, and a molded depth of 42 feet, displacing, when fully submerged, 13,000 tons. Under water, the vessel would be driven by electric motors, drawing their energy from storage batteries, giving a speed of 3 knots an hour; and on the surface the propelling mechanism would be an engine of 1,500 indicated horse-power functioning a single screw. This engine may be either a turbine or an ordinary marine reciprocating type using steam or, possibly, a heavy-oil Diesel motor. In any case, the surface speed would be 10 knots an hour.

While the idea is to travel submerged in contact with the under surface of the ice, the boat would

**The old and the new boiler rooms aboard the "Aquitania"—an interesting study of the application of oil as a fuel**

## The "Aquitania" as an Oil Burner

### The Advantages in Economy and Operation of Oil Over Coal Firing

THE "Aquitania" was the third of the big liners of 900 feet length and over to be placed upon the Atlantic route prior to the war, the other two being the "Imperator" (1913) and the "Vaterland" (1914) now the "Leviathan." The "Aquitania," 901 feet in length and driven by turbines of 60,000 horse-power, left Liverpool on May 30, 1914, on her maiden voyage, and covered the distance to New York at an average speed of 23.1 knots, the return trip being made at a speed of 23.45 knots. At the outbreak of the war, she was converted into an armed cruiser for patrol duty. She then did duty as a hospital ship and subsequently as a transport in the conveyance of American troops. Subsequently to the armistice she was used in the repatriation of troops, after which she once more took up her regular work as a passenger ship.

At the close of last year she was withdrawn from service and sent to the Armstrong yard for a thorough reconditioning, and for the reconstruction of her bunkers and the installation of the necessary plant to enable her to burn oil fuel in place of coal. After eight months out of service the "Aquitania" recently made her first visit to this port, which she reached on the day when the "Resolute" and the "Shamrock" failed to race because of the rough sea which prevailed off Sandy Hook. The accompanying photograph was taken from the Committee boat while the two yachts were reaching out past the "Aquitania" to the lightship. It serves to show that a rather nasty sea was running.

The change from coal to oil involved the reconstruction of the coal bunkers to enable them to serve as oil tanks. To this end the bulkheads were stiffened and all joints were made oil tight. "Wash" bulkheads were fitted to prevent surging of the oil. The side bunkers extend for 370 feet along each side of the ship in the wake of the boiler rooms, and they are generally 18 feet wide. There are also three large athwartship bunkers. All of these have been converted for oil carrying. Also, six tanks in the double bottom have been similarly converted.

The total capacity of all tanks is 7,800 tons. This is sufficient for a round voyage from New York to Liverpool and back, which means that the oil can all be shipped at New York. The tanks are fitted with steam-heating coils for cold weather, except those athwartship, which receive sufficient heat from the boiler rooms to ensure the proper fluidity of the oil at all times.

The system of burners, etc., is known as the White low pressure, after its inventor, Mr. W. A. White. This is the system used in the new installation on the White Star liner "Olympic," as referred to in a former issue of this journal. In this system the oil is sprayed by pressure, no compressed air being used. To prevent the possibility of a shut down, a duplicate set of pumps and heaters has been provided for each group of boilers.

Along both sides of the ship, for the length of the boiler rooms, there extends an 8-inch suction and filling main, and four connections to the filling pipes are provided on each side of the vessel. The capacity is such that the whole fuel supply of 7,800 tons can be taken aboard in 6 hours from a tanker lying alongside. The value of this in shortening the turn-around of the ship in port will be evident.

From the point of view of the marine engineer, the paramount advantage of oil fuel is the reduction of the boiler room force and the prevention of the loss of steam pressure, which occurs whenever fires have to be cleaned in coal firing. The "Aquitania" has 21 double-ended Scotch boilers with a total of 168 furnaces. It was the practice to clean 28 of these fires

## What Is an Asphalt Road?

### Some Facts Regarding the Use of This Material for City and Rural Pavements

IT is a surprise to many persons when they realize for the first time how importantly asphalt enters into their daily lives. For instance, the roof of your house is probably asphalt in the form of prepared roofing, asphalt shingles or "gravel" roofing; if your work is in a factory you will find the boilers and smoke stacks coated with asphalt paint, and if it is an up-to-date plant the floors and stairways are probably of asphalt mastic; the wires of your telephone are insulated with asphalt; the swimming tank where you bathe and the reservoir from which your water comes are water-proofed with asphalt; then when you cross the street, your rubber heels, whose toughness is due to the asphalt they contain, come down with the well-known springiness on a smooth asphalt pavement.

A large percentage of the pavements in America are asphalt pavements—and this includes the paved roads in the country as well as asphalt streets in the cities. Only the engineers who design pavements and the contractors who lay them know how difficult it is to construct a pavement that will stand up under the tremendous traffic of today, when loads of fifteen tons are not uncommon. Every imaginable material has been tried—stone, gravel, wood, concrete, brick—but the majority of city pavements laid today are asphalt pavements of the well-known type.

Most persons have a very hazy idea of what an asphalt pavement is. Generally speaking, there are three kinds of asphalt pavements. The one most usually found in cities where the traffic is very heavy is known as sheet asphalt, which, as the name implies, resembles a smooth sheet laid over the roadway. Although it is an "asphalt" pavement, asphalt itself is only a small part of the pavement, though the most important.

The pavement is built by laying first a foundation consisting usually of about six inches of concrete, though a bituminous, an old brick pavement, or an old macadam road makes a good foundation or base. On this foundation the asphalt mixture is laid in two courses; the first, or binder course, consists of a mixture of hot asphalt, sand and broken stone, mixed in a special asphalt plant, hauled to the street, then raked out and rolled with a heavy roller.

# Succeeding in Railway Mechanical Engineering

## A Profession Which Offers Exceptional Opportunities to the Trained Mechanical Engineer

By Raymond Francis Yates

RAILWAY mechanical engineering is a special branch of mechanical engineering necessitating a college training of from four to six years. It is a profession that has a larger following in the United States than in any other country in the world, due to the extent of our railway systems. This means also that there is a greater future for the railway mechanical engineer in this country than in any other. America's wealth has been made possible by her railroads; her future depends largely upon them. The young man entering this field can feel that he is associating himself with a stable profession that will give him any future his ability and capacity justify. It is a field in which big deeds are possible and one in which big deeds are recognized.

The author is enabled to outline the field of railway mechanical engineering through the kind and unselfish assistance of a man who is well known in the field but too modest to be quoted. This man has been in a position to survey this field for a number of years, and what he has had to say regarding it can be taken as good, sound advice. If more young men would heed the advice of successful men in the field they contemplate entering, there would be more successes in life than there are at the present time.

It has been the custom of the writer in the previous articles of this series to outline briefly the importance of each engineering profession to the welfare of the country. There is no profession, of course, that is *the* most important. All of them are important, but some of them are relatively more important than others.

It has been stated previously that the wealth of the country has been largely developed through the agency of the railroads. The prosperity of the country then depends to a very great extent upon the efficiency and economy with which its transportation systems are managed. This, in turn, depends largely upon the railroad mechanical engineers who, in a way, stand guard over the largest and most perfect transportation systems in the world. The railway mechanical engineer renders service of the most valuable nature in improving the design of cars, locomotives, etc., in the general interests of operating efficiency and economy. It is through the honest efforts of these men in the past that we have the most powerful, fastest and most efficient locomotives in the world. Few stories of industrial development and progress have more romance, more daring and more interest in them than that of the railroads of the United States.

*NO field is more fascinating to the average young man than that of railroading. There is a spirit of action abroad in all fields of railroading, whether it be in the running of trains, dispatching, sorting out cars in the yards, repairing the rolling stock, or even in the offices where the entire business of railroading is boiled down to so many figures on the leaves of the ledger. In the present article Mr. Yates has to do with the work and the opportunity of the railway mechanical engineer. Few fields offer greater inducement to the technically trained man than this profession; for after all is said and done, the railroads are the very arteries of any nation and railroading is the one essential work of all time. The present article is one of a remarkably complete series of articles appearing regularly in these columns and having to do with the opportunities in various trades and professions open to ambitious young men.*—THE EDITOR.

What must the training of a successful railway mechanical engineer be? The length of time that an engineer must spend in training varies. In the ordinary case four years of intensive college training will suffice. The length of time that a man should take for education along this line depends to a great extent upon the size of the road with which he expects to follow his profession. If it is a small independent road, probably the four years' training will equip him to master easily all the problems it may present. On the other hand, if he contemplates a more successful career and wishes to become connected with one of the larger railroads of the country, more time must be spent in preparatory work. In fact, some of our better engineers have spent years in training, supplementing their college courses with several years spent in the shop and designing room. A few have made short cuts and have attained their title within a few years; but a man cannot really call himself a thoroughly trained railway mechanical engineer until he has spent some time gaining practical experience in the railway mechanical department. It is here that he gets his first really thorough understanding of the construction and maintenance of the equipment. Although a few of our large colleges are fairly well equipped for the teaching of this profession, none of them is able to construct locomotives, box cars or other rolling stock; experience along this line must be gained with large manufacturers such as the Baldwin Locomotive Works or the American Locomotive Works. It is also possible to gain this experience in some of the good repair shops of the railroads where equipment is being continually overhauled and repaired.

The gentleman interviewed informed the writer that there have been many successful railway mechanical engineers who were self-trained. These men have proved beyond all possible doubt that there is a future for the man who cannot go to college and yet who has a desire to succeed in this particular field. The men in question possessed marked mechanical ability and this was probably their greatest asset. This, combined with the opportunity of associating with engineers and a continuance of home study, secured for these men practically as much technical knowledge as the average college graduate possesses.

The need for mathematics in this profession is about the same as in general mechanical engineering. The problems met are of the same general nature. Of course the study of higher mathematics is necessary, as there is no room for the rule-of-thumb man in this field. Too much depends upon a locomotive to have the design of its parts decided upon without calculation of the most accurate nature. If the connecting rod or crank pin of a locomotive traveling at high speed breaks a catastrophe generally follows in which many lives may be lost; and every railway mechanical engineer must feel the responsibility that rests with him. The writer mentions mathematics only for the benefit of the man who has decided upon training himself as he usually looks upon this as the most difficult thing he has to accomplish.

One of the most necessary qualifications for a young man entering this special field of engineering is natural engineering ability and initiative. It is not exactly a vocation for the admirer of "white shirt professions." A man entering this field has to be a worker, one who is not afraid to dirty his hands and get mussed up out in the shop, as this is all part of the training. A locomotive is not a clean thing to play around, and during the shop experience of the engineer a certain amount of this work is essential. Second in importance to natural engineering ability, a young man must have a fair supply of determination. Of course determination is necessary for success in any field but not of this particular brand. A man must have determination in this field in order to get "those high up" to adopt his recommendations. This requires faith and no little perseverance.

The salary of a railway mechanical engineer is a difficult thing to state definitely. It depends upon the size of the railroad. Of course the larger roads have more money, require greater talent and are willing to pay for it. About the best salaries that are being paid at this time are in the neighborhood of $6,000 per year. They range anywhere from $2,000 to this figure. Of course, the writer does not mean to infer that $6,000 is the absolute limit for a man of exceptional ability. The American Association of Engineers recently made some very definite recommendations regarding the salaries which mechanical engineers of this type should be paid.

A word about the future of railway mechanical engineering. Of course this depends entirely upon the development and progress of our transportation systems and one who realizes how this has gone forward in the past need have no concern about its future. The railroads of this country simply have to keep growing. There is a very good future for this profession as the increasing costs will make it necessary to incorporate greater refinement in locomotive and car design. This will create a demand for men who are capable of a higher quality of engineering work than was thought necessary in the past. In other words, during the past the railroads were not so much concerned with minute details of efficiency as they will be in the future. This makes the field more promising for the man with extraordinary ability and unusual training. It will call for the best there is in men with higher engineering talent.

Very few, if any, railway mechanical engineers go into business for themselves even in a consulting practice. In fact they would not have many people to consult them as the big railroads have engineers of their own and do not find it necessary to go outside of their own organization for advice. Most engineers consider that their first connection with a railroad is only a stepping stone to something higher up. There are many positions on a railroad for which an engineer may qualify. There is the position of mechanical superintendent, superintendent of motive power and other good and remunerative positions in the operating department.

With the great importance and extent of our railroad systems in this country the reader will probably be surprised to learn that only two or three of our colleges offer really worth while special courses in railway mechanical engineering. In general these courses are about as satisfactory as most of the other engineering courses. This is not saying that they are perfect by any means, and probably the next few years will see a marked improvement in the training offered along this line.

What course should the young man follow who desires to become a mechanical engineer and who cannot enter college? In general it can be said that there is a fair chance for any young man to become a self-trained railway mechanical engineer. There is probably more chance in this field than in most technical professions.

First, a position should be obtained in a railway repair shop or in the shops of one of the large American locomotive manufacturers. This work will bring a man into daily contact with locomotives of all types and he can see them being taken apart, repaired and assembled. If he uses his eyes, his head and a note book the most valuable part of his education can be obtained in this manner. Aside from this, a study of general mechanical engineering should be followed. This can be followed as a night course in a local school or as a correspondence course. There is still hope for a man unable to take up either one of these courses. Intensive study of the subject will eventually bring success although it will require a greater length of time.

## Utilitarian Fruit Wrappers

THE fruit wrapper, first used in Pacific coast fruit industries, for many years had a prejudice to live down in the East. The East still typically sends apples to market unwrapped. The Eastern idea has always been that wrappers for fruit were a superfluous luxury, and though the Western wrappers are now taken as a matter of course, it being apparent that they are an established thing, there is still little appreciation of their utilitarian value.

Any fruit wrapper tends to prevent decay, as the individually-wrapped orange, pear, apple or lemon has a measure of protection from outside. As the wrapper has come into extensive use, moreover, there has been great improvement in wrappers.

The consuming public little realizes it, but much of the high class Pacific coast fruit it eats is prevented from decaying in transit by chemical agents in the fruit wrapper used. Not any paper will do for a wrapper, but a special fiber wrapper chemically treated to do quick, efficient work when the fruit is bruised. Decomposition, as is generally known, starts with a bruise. The effect of the special wrapper is to cling close, dry up the escaping juice, harden the spot and kill bacteria.

Fruit wrappers are doing this thing daily, not occasionally but in innumerable cases. The economic loss averted is enormous. Fruit wrappers are not a commentary on a civilization given to super-refinements of luxury, but to a race careful to stop the small leaks.

# Electrification in Brazil

## How the Sao Paulo Railroad Is Following the Example of Its American Namesake

By Robert Carlton Brown

THE recent announcement of the forthcoming electrification of a portion of the lines of the Paulista Railway in the State of Sao Paulo, Brazil, has aroused great interest in railway and electrical circles of South America, the United States and Europe. The electrification was decided upon only after the company had made an exhaustive investigation of its possibilities. Simultaneously with the announcement of the letting of the contract, work on the manufacture of equipment for the great enterprise was begun in the United States.

The initial enterprise on the Paulista Railway will extend over a line forty-four kilometers in length from Jundiahy, the southern terminus of the Paulista Railway, northward to Campinas. The railway is double-tracked over the whole of this distance.

This installation calls for twelve electric locomotives, eight locomotives for freight service and four locomotives for passenger service. The freight locomotives will weigh ninety metric tons each and the passenger locomotives 110. These locomotives will be operated at a tension of 3,000 volts of direct current. They will take their power from two overhead copper trolley wires by means of a pantograph operated by compressed air. These locomotives will each contain four motors connected with the locomotive driving axles by means of double-spring gears and pinions. The locomotives can be controlled by one man with the ease that a street car is operated.

Electric power will be furnished to the railway by the Sao Paulo City power company, which will deliver three-phase, sixty-cycle power at 88,000 volts. It will be distributed along the lines of the Paulista Railway for connection at the various power substations which will be eventually installed. For the operation of the electric locomotives over the initial section, a power substation will be installed midway between Jundiahy and Campinas.

This substation will convert the 88,000-volt alternating current into the 3,000-volt direct current for delivery to the overhead trolley wires. The equipment for this substation, which will have a total capacity of 4,500 kilowatts, will include a system of three motor-generator sets of a capacity of 1,500 kilowatts each. These will consist of 2,300-volt, three-phase, synchronous motors, directly connected to two 1,500-volt generators. These will operate in series and will give the potential strength of 3,000 volts required to operate the locomotives on the line.

There also will be included with each motor-generator set, and mounted on the same shaft with the motors, an exciter which will provide excitation for the two generators. The 88,000-volt current which enters the substation is stepped down to 2,300 volts for connection to the motors by means of transformers. A switchboard with automatic switching equipment and meters also will be provided for measuring the current which enters the station as well as that which is delivered to the trolley system. These automatic switches will be so designed as to provide the maximum protection to all apparatus as well as to the operators against any possible accidents. The lines will be further protected against lightning by means of electrolytic lightning arresters. The trolley wires will be supported by means of the well-known catenary type of overhead suspension, especially developed for high voltage, heavy traffic and high speed service. The steel rails used for the present system of steam locomotive service will be connected by means of copper bonds to establish the return circuit.

Materials for the new work will begin to arrive in Brazil from the United States within a few months and the railway company will immediately begin work on the electrification, assisted by engineers of the electric company. The installation of the power transmission lines and the overhead trolley system will be started first. Work will also be started at once on the first substation and it will be ready to receive the machinery on its arrival. The huge locomotives will be the last of the equipment to arrive. These will be unloaded at the port of Santos. They will be assembled there and will proceed to Jundiahy over the rails of the Sao Paulo Railway. It is expected that the electrified system will be in complete operation by July, 1921.

One feature of the electrification will be that the direct system of current will be used instead of the usual alternating current. The locomotives to be used will be provided with the regenerative braking system, whereby the locomotives and the trains when descending a grade generate power which is returned to the line. The speed of trains descending grade can be very accurately controlled by this system and at the same time power is being generated. Further advantages of this system include elimination of difficulties incident to the use of the airbrakes on heavy freight trains when descending grades; elimination of brake-shoe and wheel wear with resultant reduction in maintenance; reduced wear on tracks, especially on severe curves; and entire absence of grinding of the brakes which is especially disagreeable on a heavy passenger train.

Economy is the big factor in favor of electrification of railways, although there are many other arguments to be advanced in favor of the replacement of steam locomotives by the electrical equipment. The high cost of coal has always been a leading item in the expenses of the railways of Brazil and it is believed by many observers that the coal question will eventually result in the electrification of most of the railway systems of the republic. Electrification is peculiarly practical in Brazil in view of the great abundance of waterfalls. Excellent waterpower is easily available to a large portion of the railway area of the country.

Experts of the electric company who are in Brazil on the Paulista enterprise summarize the advantages of electrification under two leading heads. One of these

### Seeing in the Dark

To the Editor of the SCIENTIFIC AMERICAN:

In the article, "Detecting Men by Their Heat Radiation," in your issue of March 27, 1920, it is stated that my instrument "can detect the difference between the painted and unpainted sides of a steel plate, of which the temperature is slightly higher than the surrounding atmosphere."

The interesting fact is that on *clear nights* the instrument readily detected the difference between the painted and unpainted sides of an invisible steel plate which had the *same* temperature as the surrounding atmosphere. And, furthermore, the side of the plate which was painted black gave an indication similar to that which would have been given by a body considerably warmer than the atmosphere, although there was no question of the fact that the entire plate was at the same temperature as the surrounding atmosphere. This result was in direct contradiction to what had been predicted from previous laboratory tests on a *cold* body, in which the blackened metal gave a considerably *colder* indication than that given by the unblackened part (both parts being of course at the same temperature). An analysis of these laboratory results led to the conclusion that the large cold indication of the blackened surface was, of course, a measure of the true temperature of the metal, while the warmer indication of the bright metal was caused by reflected energy from the walls of the apparatus which were at the higher temperature of the room. This unexpected result seemed entirely to negative my method and I took care that news of it did not get to Washington until I had made some actual field trials. Many authorities held that the radiation from objects such as men would be entirely obscured by the effect of the surrounding atmosphere and the background, and this laboratory test was held to support their view. However field tests showed that I was right and they were wrong, and resulted ultimately in the very successful results alluded to in your article.

I might add that the reason for the cold indication of the bright metal when in the open, on clear nights, was reflection of the intense cold of interstellar space, or stated more correctly, a cooling of the blackened surface of the thermopile by radiation into space. It was this fact that rendered it so easy to detect aircraft on clear nights, as the plane, coming between the instrument and the outer sky, acted as a shutter to stop this radiation into space, and resulted in giving a large warm indication.

San Francisco, Cal. SAMUEL O. HOFFMAN.

### Cleaning the Clock

To the Editor of the SCIENTIFIC AMERICAN:

As a reader of your publication for more than thirty years, twenty or more of which have been spent in the repairing of all kinds of time-pieces, I wish to protest against the printing of such ideas as those contained in a recent article on the use of kerosene as a cure for dirty clocks.

The oil used on clocks is as near non-drying as is obtainable but even the best will dry up somewhat after the long time between cleanings. As there is less than two drops on the whole outfit of pivots in the ordinary type of clock it can be easily seen that the supply is small and not renewed from oil-cups as in many other types of machine. Also the clock is more or less open to the air around it which has a great deal of dust floating in it ready to stick to anything fluid like the oil around the pivots. This tends to thicken the oil and to work into pivot-holes, serving as an abrasive to cut the pivots.

The only way to relieve the condition is to take the clock completely to pieces and clean each and every piece; to "peg out" each hole; polish the cut or worn parts and then to assemble the whole for proper oiling on clean metal.

The use of kerosene on a tuft of cotton is as much good in the manner given in your article as it would be in removing carbon from the cylinder of an automobile by placing a cloth wet with the "panacea" on the floor of the garage under the machine.

Newton Center, Mass. F. W. WOOLWAY.

### Measuring the Flow of Liquids

To the Editor of the SCIENTIFIC AMERICAN:

In the June 19th issue of the SCIENTIFIC AMERICAN we notice a description of instruments for measuring and recording the flow of liquids, recently brought out by a large British firm.

The description is so exact that we have no difficulty in recognizing this as the device originated by Mr. Lea, mechanical engineer of Manchester, and the only reason of our writing to you is because of the inaccuracy of the statement that this has been recently brought out.

As a matter of fact our clients have been the American manufacturers of this instrument on which they hold several patents on improvements since 1911. We know that several thousand of these are in use in many of the largest plants in this country, Great Britain and other parts of the world.

The device is not new but is a well-established and time-tested device.

Philadelphia, Pa. R. G. E. ULLMAN.

### Invention vs. Re-invention

To the Editor of the SCIENTIFIC AMERICAN:

Your article, "A Boat That Pumps Its Way Along," in the issue of the SCIENTIFIC AMERICAN of June 12 and the illustration of the same is certainly another proof, as you say, that "history is forever repeating itself." The principle involved in the propulsion of this boat is identical with that James Rumsey used about twenty years before the "Clermont" went up the Hudson. Of course he had none of the fine mechanism of modern times, but the boat was propelled by taking in water near the front of the boat and expelling it in the rear. Undoubtedly this was the first application of steam to navigation. Recently the state of West Virginia has erected a beautiful monument overlooking the point in the Potomac River at Shepherdstown, West Virginia, where the first demonstration was made by Rumsey December 3, 1787. No one will claim that the old "Constitution" is anything to compare with the modern dreadnought, and, of course, Rumsey's crude beginning is in the widest contrast between the modern floating palace, but honor to whom honor is due.

THOS. C. MILLER.

Shepherdstown State Normal School.

# Seeing in the Dark

## An Account of the Success Obtained During the War in Detecting Invisible Objects by Their Bodily Heat

By Samuel O. Hoffman, formerly of the Science and Research Division, United States Army

WHEN in the early years of the war the horrible nightly Zeppelin raids commenced, attention of engineers all over the world was directed toward finding a means of combating this menace. The time of occurrence of these raids, always at night, suggested the solution of the problem. Remove the enshrouding darkness and the raiders would fall easy prey to artillery fire and the fast combat planes. As the war went on and degenerated into the deadlock of trench fighting a much greater need arose for the same device. Trench warfare was almost entirely a matter of night activity. Scouting and patroling, raiding, wiring, and other work was done almost entirely under cover of darkness. Although at night the front was a beehive of activity, any circulation in daylight, even far in the rear, quickly drew enemy fire.

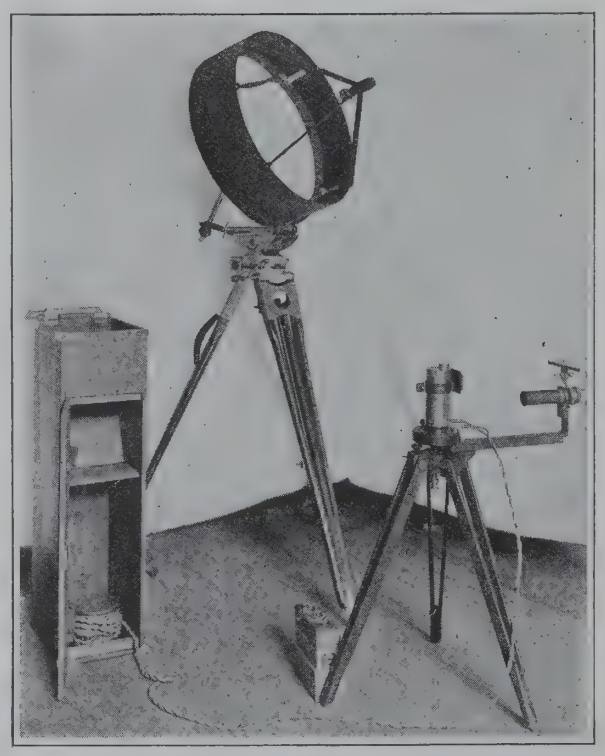
It can be thus seen that an urgent need arose for nothing less than a *sixth sense*, a means of seeing in the dark. It is apparent that if either side had had such a device they would have had a preponderating advantage, and, at the very least, trench warfare would have been profoundly modified. Curiously enough, results have shown that such a device *is* practicable, and it was in fact subsequently worked out, although too late to be used in trench warfare.

The question will be asked, Did not flares and star shells supply this need? Emphatically not. In the first place, they were equally available to either side. They gave only intermittent illumination; and the enemy, caught in the glare of a star shell, knew he was under observation and by remaining motionless could escape detection. Moreover, these methods were useless for detecting aircraft at night.

For a number of years prior to 1915, the writer had devoted the greater part of his time to investigations involving infra-red radiation, and his familiarity in this field immediately suggested that here was the solution of the problem. This radiation is the ordinary dark heat such as is felt on bringing the cold hand an inch or so in front of the face. While of the same general nature as light, it has quite different properties. Hardly any substances are transparent to it, rocksalt being the only one easily obtainable. Glass is particularly opaque, so that ordinary optical instruments are useless. However, sharp images can be easily formed by using concave mirrors of ordinary dimensions, as the actual wave length of this radiation is sufficiently small (1/2500 inch) to obviate trouble from diffraction. This is the reason for the great superiority of this radiation over sound waves for detecting purposes in the dark, for with any available sound waves (in air) it is possible to form a sharp image only with monstrously large apparatus.

By the middle of 1915 the problem was pretty well formulated, the amount of energy available was calculated, and it seemed certain that the whole idea was practicable. Attempts were made to interest several branches of our own War Department, the British War Office, Admiralty and Inventions Board, and several other agencies. Almost everywhere the idea received attention and courteous replies—and nothing more. Ideas were at a discount. What was wanted was developed apparatus.

A year or so went by and the early part of 1918 found the author in New York with two weeks' unofficial permission to show what could be done. It was easily demonstrated experimentally that there was a large amount of dark radiation available, and that the detection of this radiation would not require very delicate instruments. These experiments were made indoors with a warm body, and as an afterthought the device was tried with a cold body, with apparently contradictory results, for the indicating instrument moved in the opposite direction to that expected. A quick analysis showed the reason for this to be reflection from the walls of the room, and it seemed that this fact would render the device inoperative in the field. The apparatus was hurriedly reconstructed, and



The complete instrument for detecting men in the dark, set up for use. The large tripod carries a 24-inch parabolic mirror, with the thermopile in focus. The small tripod holds the indicating galvanometer

**Complete outfit for enabling soldiers to detect the enemy in pitch blackness**

the following night a test was made on the roof of the laboratory. The result was a complete vindication. Every object sighted on gave a definite indication, some being several hundred feet away. These results were of more value as the mirror used was only 4 inches in diameter, the largest that could be found in New York. Shortly after this roof test official permission was given to continue the work.

The apparatus used in these tests was as follows: A concave mirror was used to concentrate the infra-red radiation on the blackened surface of a thermopile, which consisted of minute wires of bismuth and silver soldered together. The radiation concentrated on this blackened junction was absorbed, heating it slightly. The resulting electric current, flowing through a galvanometer, indicated when the apparatus had spotted something warm. It can be seen that this apparatus was very simple, extremely rugged and portable. Aside from some dry cells to operate the galvanometer lamp, no source of power was required. A potentiometer was necessary to make the device practicable, as it usually happened that the background was a different temperature from the surface of the thermopile, and it was necessary to compensate for this.

During the next few weeks trials were made almost nightly with all sorts of backgrounds and weather conditions. The results were uniformly successful. Men could be detected with startling ease when 600 feet away. The effect on the apparatus was the same whether they were crawling slowly or running rapidly. To simulate a sentry looking out over No Man's Land, a soldier lay in a depression in the ground and lifted his head from time to time. He was detected unfailingly as soon as his head appeared above ground, although at a distance of 400 feet and absolutely invisible to the eye. The murderous possibilities of such a device attached as a sight to a machine gun and trained on men in the dark can be imagined. Ranging the instrument in front of and parallel to our front line would constitute an arrangement for preventing raiders from creeping into our lines undetected.

A report of these results was immediately sent overseas, and, anticipating a favorable reply, the standardization and construction of the apparatus was rushed. Navy searchlight mirrors were used, cut down to two-thirds of their original diameter, thereby obtaining a good optical figure. The mirrors were silvered on the surface, and though they tarnished rapidly, this did not seem to affect the sensitivity and rendered the mirror less conspicuous in the glare of a searchlight. The design and construction of the thermopiles took several months. There was no bismuth wire available in this country, the product formerly coming from Germany. The making of this was immediately attempted, and pliable wire about the diameter of a human hair was successfully produced. About 40 different designs of thermopiles were tried out before a satisfactory design was obtained. This work, all done by enlisted men in the Army, was very tedious. It was necessary to work under a binocular microscope, using special tools. It is interesting to note that no thermopiles of the final design have ever broken in use. So sensitive were these thermopiles to changes in temperature that it was necessary to shield them very carefully from drafts and sudden temperature changes. The enclosing case was made of very heavy metal, the radiation entering through a narrow slit which was covered with a plate of polished rocksalt. The rocksalt had a slight coating of varnish to protect it from the moisture in the atmosphere. Special galvanometers were constructed, and the whole apparatus was extremely compact and self-contained.

About the time this work was finished, a cable arrived from general headquarters of the A. E. F. asking for immediate shipment of the device for test at the front. It went overseas in August, 1918.

So far particular attention had been given to the use of the device in trench warfare. By this time,

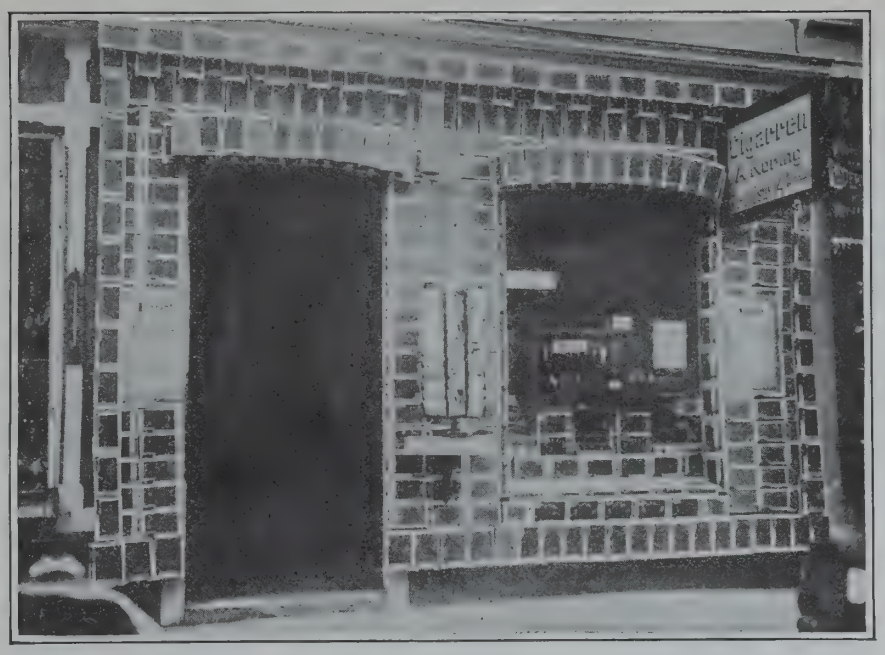
### A Store Front of Cigar Boxes

IT is peculiar to study the impressions that persist year after year regarding various peoples, and that are never revised despite the ever-growing evidence that such impressions are erroneous. For instance, and this is the case in point: The Germans have the reputation abroad of being anything but original and inventive. We regard them as a very thorough and painstaking people, ready to adopt and improve upon any idea which they come across, but not as originators. However that may be, there is daily proof to the effect that the Germans are highly imaginative and original in their own way.

Perhaps it is an aftermath of the war, but at any rate the Germans have been displaying unusual ideas in the field of advertising and publicity of late. Recent expositions in Germany have brought forth almost no end of ingenious publicity "stunts," proving once and for all that the Germans are creative along certain lines.

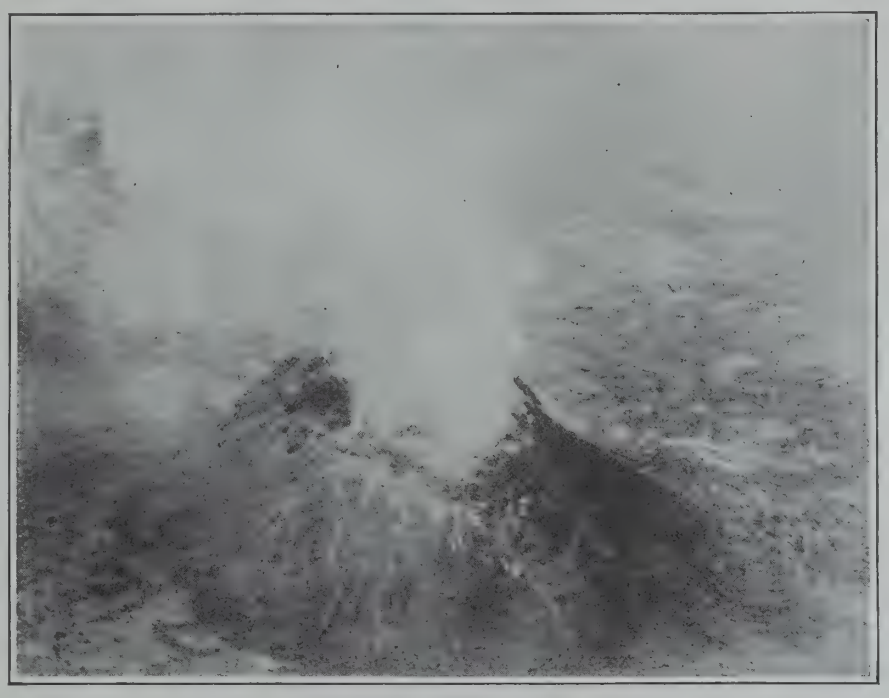
The accompanying view offers an example of this German ingenuity. Here is the store front of a cigar dealer who, finding business somewhat slow, went to work and built a front out of cigar boxes. This store, situated in Bremen, never fails to attract attention from passers-by.



**This Bremen store front covered with cigar boxes never fails to attract the attention of passers-by**

### A Close-Up of Vesuvius

THE accompanying view of the crater of Vesuvius is due to the risk taken by an American Red Cross worker in Italy. It was taken from a point close above the molten lake of lava surrounding the inner cone of the famous volcano. Every few minutes showers of lava and huge stones were ejected from the cone crater, but through good fortune the photographer escaped unharmed.



**A close-up of Vesuvius made by an American Red Cross worker in Italy, at a considerable risk to himself from the showers of lava and huge stones**

### To Make Asparagus Keep

CUT asparagus exposed to drying winds in the open air will become unmarketable in 48 hours, and of poor quality in considerably less than that time. Cut asparagus handled by a person who knows how—any boy or girl can turn the trick—will keep in marketable condition for 12 days. What is more, it will have gained 50 per cent in weight!

Sounds improbable, doesn't it? But it isn't, having been demonstrated in recent experiments at the Oregon agricultural college. The demonstrations should prove of tremendous benefit to family households, to gardeners, and to retail stores.

There are several ways of handling cut asparagus, of varying degrees of efficiency. Exposure to dry air is the least desirable way; a better way is to place in a moist chamber. In a glass case free from a direct air current, asparagus will not wilt though kept 12 days, and will not lose either weight or length. Asparagus stalks, the butts of which are placed in water, placed in the open air, will keep in good marketable condition for 12 days and will increase somewhat in weight.

### The Latest Portrait of the Largest Lady in the Land

WHAT is the accompanying photograph? At first glance it might mean almost anything from a little known variety of shell fish to a new kind of harvester. Even a seasoned New Yorker would not recognize this latest portrait of Miss Liberty—the largest lady in the land.

In order to secure this unusual view of the Statue of Liberty an intrepid photographer climbed out on the torch of the statue and took a photograph looking down on the head. The result is exceptionally striking, and serves to convey an excellent idea of the magnitude of this statue which was brought to this country from France in sections and assembled on its pedestal in New York Harbor. The inside head measurement from ear to ear is exactly ten feet.

### Facts About Chinese Eggs

THE standard egg case used in the United States and Canada holds 30 dozen eggs. It is an oblong box, divided into compartments by a partition on either side of which 15 dozen eggs are placed, three dozen to a layer. Between the layers, and between eggs in a layer, cardboard forms an individual safe box for each egg. A cardboard device called the "filler" is universally used.

The standard egg case in China is a two-compartment box in which kerosene, two 5-gallon cans to the box, arrives in the country. The Chinese thriftily reship it filled with eggs. Its capacity is 280, 300, or 360 eggs, according as the eggs are of large, medium or small size. If the eggs are small, the net contents equal those of an American egg case.

The Chinese do not use cardboard "fillers." Instead they use rice hulls, wheat bran, kaoliang bran, or sawdust, and they pack the eggs in regular layers, with skillful distribution of the sawdust or other filling material to prevent breaking. The method is successful. When rice hulls are used, the cost is estimated at about five cents per case.

Facts about Chinese eggs should arouse in Americans at this time much more than a polite interest—for we have been eating Chinese eggs, and Chinese egg products. During five or six years past, large quantities have been exported to this country and Canada, and marketed in large cities. The Pacific Coast is actually worried about the situation, fearing its detrimental effect on the local egg industry. Egg marks acts especially aimed at the Chinese egg, to prevent its being marketed under any deceptive alias, are now operative both in Canada and this country. Chinese eggs can be marketed at a very low price.

The market value of eggs in one Chinese province, Shantung, has risen to such an extent that an estimated three-fourths of the total "lay" is sold by producers. There are 1,500,000 hens in this province, and the average production is 84 eggs per hen. As average production goes, that figure is not low. It has been calculated by Department of Agriculture experts in this country that the average American hen produces little, if any, in excess of 90 eggs per annum. During the past two years, local egg prices have doubled in price in many parts of China, consequent on the export demand, and not long ago quotations reached the dizzy height (for the Orient) of one cent each.

Consumers and poultrymen in this country are naturally most interested in China as an exporter of fresh and preserved eggs. Yet various egg products the ordinary lay reader never heard of account for a much larger percentage of the Chinese production. These egg products are whole-egg powder, dried albumen, liquid yolk, and dried yolk. The exports of yolk in a normal year are calculated to account for over 700,000,000 eggs.

Dried albumen is put up in tins holding 100 lbs. Liquid egg yolk is shipped in barrels holding 430 lbs. net. In addition, large quantities of frozen eggs are exported. These egg products are used considerably in the baking trade.

Why were not Chinese eggs talked of before now? The reason lies in a simple economic condition. It is only within recent years that the level of egg prices in this country has reached so high that financial interests cared to undertake the costs and risk of egg collection in China, shipment thousands of miles to North America, and final sale in this country. The margin existing was not sufficient. With American eggs selling at high prices, however, the situation naturally appealed to the speculator, whose activities have caused such a stir in Pacific Coast egg circles.

# Pulp Wood from Labrador

## A Paper-Supply Likelihood of the Near Future

By J. T. Rowland

TO a person who is familiar with the northern extension of our Atlantic coast which goes by the name of Labrador, it is always amazing to discover the misconceptions concerning that region, which exist, almost without exception, in the minds even of educated and otherwise well-informed persons. The words "lonely," "remote," "desolate" seem to picture the qualities which the mention of Labrador unfailingly calls to mind, while the association with icebergs and an occasional seal imply an immediate juxtaposition to the North Pole. It follows, therefore, that one is usually met with an incredulous smile when he states the fact that Labrador lies between almost exactly the same parallels of latitude on this side of the Atlantic which the British Isles occupy on the other, and that for all the ignorance which exists concerning it, the coast is literally just around the corner from us—much nearer the northeastern extremity of the United States than Alaska is the northwestern.

**Why the coast of Labrador stays cold: One of the many icebergs to be found in the coastal waters**

The reason for our lack of knowledge—and interest—is neither the remoteness nor the Arctic aspect of the land, but the simple fact that it produces nothing which we have heretofore thought worth the trouble of going to fetch. "A few poor cod and worse pelts," as one mission doctor summed it up, have made the total of Labrador's contribution to the world's wealth. For this reason the coast has languished in disregard. Poorly chartered, unbuoyed and next to unlighted, with many of its hundreds of bays and inlets actually unexplored and the position of islands and reefs known only to unlettered fisher folk, it is small wonder that the great ships bound out from Montreal pass the coast by with a shudder and are thankful each trip when the Strait of Belle Isle has been left astern.

Some years ago I was discussing with Dr. Grenfell the possibility of Labrador's some day becoming economically useful to the world. We stood on the summit of a hill of rock overlooking beautiful Grosswater Bay, which I could see, in my mind's eye, sheltering a fleet of a thousand ships. "There is nothing in the world to keep people away," the doctor was saying, "except only the fact that there is nothing to bring them. If ever that is changed we shall be swamped!" To the medical missionary who had devoted his life to the people of the coast such a prospect had much in it which was naturally not pleasing; but whether or not Labrador needs the world, the day has come when the world needs Labrador—and what it needs it generally takes.

Climatically Labrador is divided into two regions, the coast and the interior. The former is a few miles wide and is Arctic in character, the latter is a few hundred miles wide and is what one would expect to find in the fifties of north latitude; that is to say, it is well watered, densely forested and quite similar in character to the North Woods—hot in summer and cold in winter. This amazing disparity in climate between two regions so close together is due entirely to the fact that the polar current, setting southward out of Davis Strait, prevents the seaboard from ever growing warm. There is floe ice along shore until late in the spring and there are bergs, though not in sufficient numbers to be a serious menace to navigation, all summer long; and the temperature of the sea water rarely gets far above 32 degrees. Thus, it is the Arctic condition of the coast which is abnormal, if one may use that word of an established natural condition, and it is the north temperate climate and flora of the great interior which is "normal" and as it should be; but the sea coast's forbidding aspect has so long been synonymous for Labrador that it is hard for any one to believe that there can be anything but barren tundra behind.

I shall never forget my own surprise at my first glimpse of the hinterland. We had been for days skirting the coast in one of Dr. Grenfell's hospital launches and had seen nothing but ice and bare rock—not a bush or a blade of grass. At last we swung west around a great headland and started threading our way up a narrow defile between immense hills of a blackish rock. After about a half hour's steaming we came upon a little clump of dwarfed tamarack nestling in a hollow. Then suddenly the vessel turned a sharp corner and we came out abruptly upon the waters of a beautiful big lake, surrounded by gently rolling hills covered to the water's edge by a forest of spruce and tamarack so dense that one could see scarcely ten feet back into it. The air here was warm and the sky overhead blue; we felt as though transported back by some magic to the shores of an Adirondack lake. Yet this was all deep water, easily navigable by the largest ship. Perhaps half a dozen white men at most had ever seen it before us.

This description will fit, with modifications as to distance, the head of almost any one of a nearly innumerable series of inlets and fjords, for the coast is very much indented and looks on the chart almost like the fringe of a rug. Hamilton Inlet penetrates the farthest—nearly 150 miles straight back from a line drawn across the outlying headlands—and its inner half, Lake Nelville, is a veritable inland sea of about the size and shape of Long Island Sound. When I last visited this water its shores were strewn with quantities of saw logs from a raft which had broken up in a storm. This was the aftermath of the efforts of a half-baked Nova Scotia concern. It lacked the equipment to collect the logs, and it did not long survive their loss.

More recently, however, the knowledge that there is behind that forbidding, desolate coast an almost limitless supply of readily accessible wood has begun to attract interest for purposes other than lumbering. Pulp wood is every year more greatly in demand and more difficult to secure. Moreover, timber which is not sufficiently tall or heavy for profitable lumbering is commercially valuable for pulp wood. In many cases this has resulted in denuding forests of their young growth. Labrador is probably the one place on earth where this would do no harm, unless it be to an occasional spruce hen. The country is singularly devoid of game.

The timber consists chiefly, almost entirely in fact, of spruce (*Picea nigra*) and tamarack (*Larix americana*). In size it runs from a few inches to two feet in diameter at the butt. The farther inland one penetrates the larger the timber grows, but my personal observation has been that two feet is about the limit, except for occasional trees. It grows most abundantly around the heads of inlets and along stream courses. The higher hills are bare, as are likewise considerable stretches of elevated plateau.

Roughly speaking, the northern limit of the timber is in about 57 degrees north latitude. At least I have seen none to the northward of this at a distance some fifteen or twenty miles back from the coast, though at Davis Inlet in 55° 50′ it is abundant. This means that there is a belt of timberland some 400 miles long, north and south, which is immediately accessible by navigable waterways to an average depth of perhaps 30 miles, without counting the great interior basin of Hamilton Inlet. The timber is suitable for pulp wood and is of little or no value for any other purpose.

A pulp wood enterprise has already been undertaken upon the Alexis River, on the southern portion of the coast, not far from Dr. Grenfell's hospital and mission post at Battle Harbor. Others will doubtless follow and it may be that the inundation of the "lonely Labrador" by foreign workers is just around the corner of the future if given adequate means and knowledge.

## Harvesting the Hay the Latest Way

By Arthur L. Dahl

THE United States is about to harvest the greatest crop of hay ever produced, estimated at 111 million tons. Lack of farm labor is largely responsible for the record crop, for areas that would ordinarily have been devoted to the growing of food crops were allowed to raise volunteer crops of hay because labor was not available to work the land. The labor shortage is just as acute in this harvest period and the quality of the hay produced will be largely dependent upon the efficiency with which the gigantic crop is gathered and prepared.

Hay making is an operation that must be done in a certain space of time that is short at best and that is always liable to be made shorter by bad weather. For this reason there is perhaps no farm operation in which system and efficiency count for more than in haymaking. Hay has been quite steadily increasing in acreage for a number of years, until at the present time it occupies about one-sixth of the tilled area on farms in the United States, and has an annual value on the farm, unbaled, of over a billion dollars. It has been estimated that the annual cost of harvesting our hay crop, under normal conditions, is about $125,000,000. When we contemplate this enormous amount of money it is easy to see that a reduction of even a small per cent of this cost would add millions to the profits of the hay growers of this country, and according to experts of the Department of Agriculture it is possible for every such grower to make substantial savings by using proper equipment. As a single example of the efficiency of proper implements, it has been demonstrated that one man with a team can turn more hay with a tedder than can 12 men doing the work by hand. In a period of labor shortage and high wages the use of haymaking implements is not only economical but almost necessary.

Hay is the bulkiest crop grown on our farms, and its cutting, curing and stacking require a great deal of power. Efficiency in haymaking, therefore, turns on the utilization of the cheapest and most abundant power. On the average farm tractor or animal power is available in abundance, even though manpower is short. Wasted human labor does not always mean idleness but more often labor expended unnecessarily on operations which are not efficiently planned and carried out.

The first operation in harvesting hay is that of mowing. Here there are a number of factors that make for efficiency and saving. The time of day when the mower is started has a direct bearing on the amount of hay made per day, and the arrangement of the moving crews likewise affects the results. The size of the mower used has a decided bearing on the quantity cut in a day, and other factors enter into the proposition.

On a great many farms the mower which will make a five-foot cut is used. This size requires the services of a team of horses and a driver, and under average conditions a 5-foot mower will cut 10 acres in 10 hours. Now if that same man and team will operate a 6-foot mower it will cut 12 acres. If the man adds another team to the outfit, or uses a tractor to pull a 7-foot mower, he can cut 14 acres a day, and if an 8-foot mower is used about 16 acres can be covered in the 10 hours. Of course the wider mowers require more power than the smaller ones, but they require no more supervision, and accordingly the labor efficiency in haymaking can be almost doubled by the use of suitable implements. Where tractors are available, as they are on a large proportion of our farms, ample power is provided to operate any sized mower.

In a study of haymaking crews made by the Department of Agriculture, it was found that the same number of men and horses will produce varying results under different arrangements. For instance, where three mowing outfits are used, and all three men work close together, one mower following the other, each cutting a swath, less work will be accomplished in a given period than where each outfit works separately. This is due to two causes. When working close together, if one machine develops trouble and it is necessary to stop, all three mowers must stop, and the lost time is multiplied by three. Furthermore, when men work close together there is a decided tendency to talk, and this interferes with their efficiency. When each outfit is placed in a given field and works alone, better results are obtained, and there is no interference from other machines.

For a long time in the South it used to be the custom, and is yet to some extent, to use a big crew of negro laborers to turn over by hand the curing alfalfa and Johnson grass. In an actual test made in the same field, it was found that a farm boy, driving a team and operating a hay tedder, could turn over as much hay in a day as a crew of 12 negroes using pitchforks or rakes. Even where labor is plentiful and cheap it is not hard to figure out the most efficient method for turning hay. A hay tedder is a simple and comparatively cheap implement and should be on every farm where hay is grown.

Raking hay is another thing that can be done more efficiently by the use of proper implements. On many farms the 8-foot rake, operated by one horse, is used for this operation, but where the area devoted to hay is fairly large, this outfit is costly and inefficient. A 12- or 14-foot rake, drawn by a strong team or a tractor, will cover 50 per cent more ground and do the

(*Continued on page 167*)

**A sweep rake used in the West. This implement is said to reduce the labor by fifty per cent**

## Shade Trees for City Streets

By Alfred Longville

PROVIDING shade on city streets is as much a municipal function as providing lights or sidewalks and should therefore be cared for by public officials, says one of the horticulturists of the U. S. Department of Agriculture in a recent bulletin on "Street Trees." Trees on well-shaded streets not only contribute enjoyment but health by transpiring moisture and producing a restful effect on eyes and nerves.

Good shade adds to the value of adjoining properties. In fact, even in pictures, a house with trees and shrubbery will attract a buyer when the same structure without them would be disregarded.

Mixed plantings of different kinds of trees are not as pleasing and effective as the use of a single species for considerable distances. On the other hand monotony will result if the same species is used for an entire town or section. The varieties of trees suitable for city planting are not many, so all native to the section may be used, usually assigning one variety for a long stretch of street. Street trees are often planted too close together for the mature tree to thrive, a common practice being to plant them 35 feet apart although 50 or 60 feet would be ultimately a better distance.

A street tree must have healthy foliage that withstands dust and smoke, a root system adapted to unusual soil conditions, restricted feeding area and root pruning where street improvements are made. In the smoky heart of a city the ailanthus or tree of heaven will probably thrive when nearly all other kinds fail. So also may the sycamore and plane. These are suitable for nearly all sections of this country. The maple is not as suitable a tree for street planting as many suppose because it is not sufficiently rugged except under suburban conditions.

The top of a street tree should be in proportion to the width of the street on which it stands, and should be of open growth without being too spreading. Narrow streets should be planted with columnar trees like the Lombardy poplar, or sometimes with small trees; broad streets with spreading trees like oaks or elms. The oak is designated as best for nearly every section of the country because of its hardiness and beauty.

## Testing Biological Products in England

THE U. S. Public Health Service Reports that the Minister of Hearth of Great Britain has recently appointed a committee to consider and advise upon legislative and administrative measures to be taken for the effective control of the quality and authenticity of such therapeutic substances offered for sale to the public as cannot be tested adequately by direct chemical means. These include biological products, such as serums and vaccines, and mineral and vegetable bodies, such as salvarsan and digitalis, to which ordinary chemical tests are not applicable. In the United States the production and sale of viruses, serums, toxins, and analogous products are under effective Federal supervision so far as interstate commerce is concerned.

# The Racing Airplane of the Future

## (Reprint of a Study of Probable Future Developments, Originally Published in the Scientific American of Oct. 22, 1910)

By J. Bernard Walker

*THIS article, originally published during the great airplane meet at Belmont Park in 1910, was an attempt to forecast the lines along which the development of the airplane would proceed. It was an engineer's loose study of a problem, to which the engineering profession was about to apply itself with results of which we were to see the culmination on the battlefields of France and in the memorable flights across the Atlantic. The present-day interest of this article will be found in its fruitful anticipation of subsequent developments, as seen in the oval, streamlined nascelle and the sheltered position of the pilot; the substitution of interior metal wing beams for exterior ties and struts; the retractable chassis; the gyro control of the ailerons; and the use of alloy metal throughout, with corrugated metal covering for the wings. After a lapse of eight years, the Germans, in the summer of 1918, produced the Junker all-metal war monoplane, with internally braced wings, covered with corrugated metal. At the present time the retractable chassis, as suggested in 1910, is being made the subject of much experimental effort.*—THE EDITOR.

A STUDY of the trend of development in airplane construction renders it possible to predict with some degree of certainty the leading characteristics of the airplane of the future, and especially of that type which will be built purely for racing purposes. The following is an attempted study along these lines. The writer has no wish to assume the rôle of prophet, and the accompanying drawings and description are based mainly upon a survey of the work which has been done during the present year of phenomenal development by the designer, the constructor, and the airman. The keynote of this development is to be found in the fact that the speed of the airplane in straight-away flight has risen during the past year from fifty-five to seventy-five miles per hour and that the "blue ribbon" of the air (if we may borrow a nautical phrase) has passed from the biplane to the monoplane, the type which, at the present writing, is so far in the lead as to speed, lightness and stability, that it stands in a class by itself.

The racer of the future, then, will be a monoplane; and in narrowing down to this type, man is but treading in the footsteps of Nature, the master builder, who, working through a process of evolution that has stretched out over millions of years, has produced, in that wonderful bird, the albatross, the perfect flying machine. The future high-speed flyer, then, will possess the same tapering, rounded body and the widespread wings of narrow width which characterize the swiftest of the birds. Langley, in his classic researches, showed that it was the leading portion of a plane which was the most efficient, and this for the reason that it was continually moving on to fresh bodies of undisturbed air. He showed that as the after portion of the plane had to do its work upon air which had already received from the forward portion a downward velocity, this air was unable to provide the effective reaction which was exerted by air absolutely inert. Hence it follows that a plane 5 feet in width by 10 feet in length would be rendered more efficient if it were divided longitudinally, and the same area were presented in a plane 2½ feet wide and 20 feet in length. The wings of the racer will be long and narrow; and when they come to be built of metal instead of the present wood and fabric, it will be possible to give them those sweeping, rounded forms which prevent eddy-making, and also, from a constructional point of view, add not a little to the strength. The body will be of a generally circular or oval section; and to allow of a long and gradual taper, for ease in traversing the air, the body will have considerable length. The greater length also will add greatly to the fore-and-aft stability in flight.

The present wood-canvas-and-wire construction will have to go. It is makeshift work at the best, and was adopted because, in the early days of experiment, it offered a cheap and light combination of material, and one which, in the event of the inevitable breakages, incidental to experimental work, could be cheaply and quickly repaired. Its place will be taken by some one of the many remarkable alloys of steel which are now available—metals of enormous strength and toughness in proportion to their weight. The use of these, coupled with careful designing by the skilled engineer, will make it possible to produce an airplane of much greater strength, that will weigh no more than the present machine, and will present far less resistance.

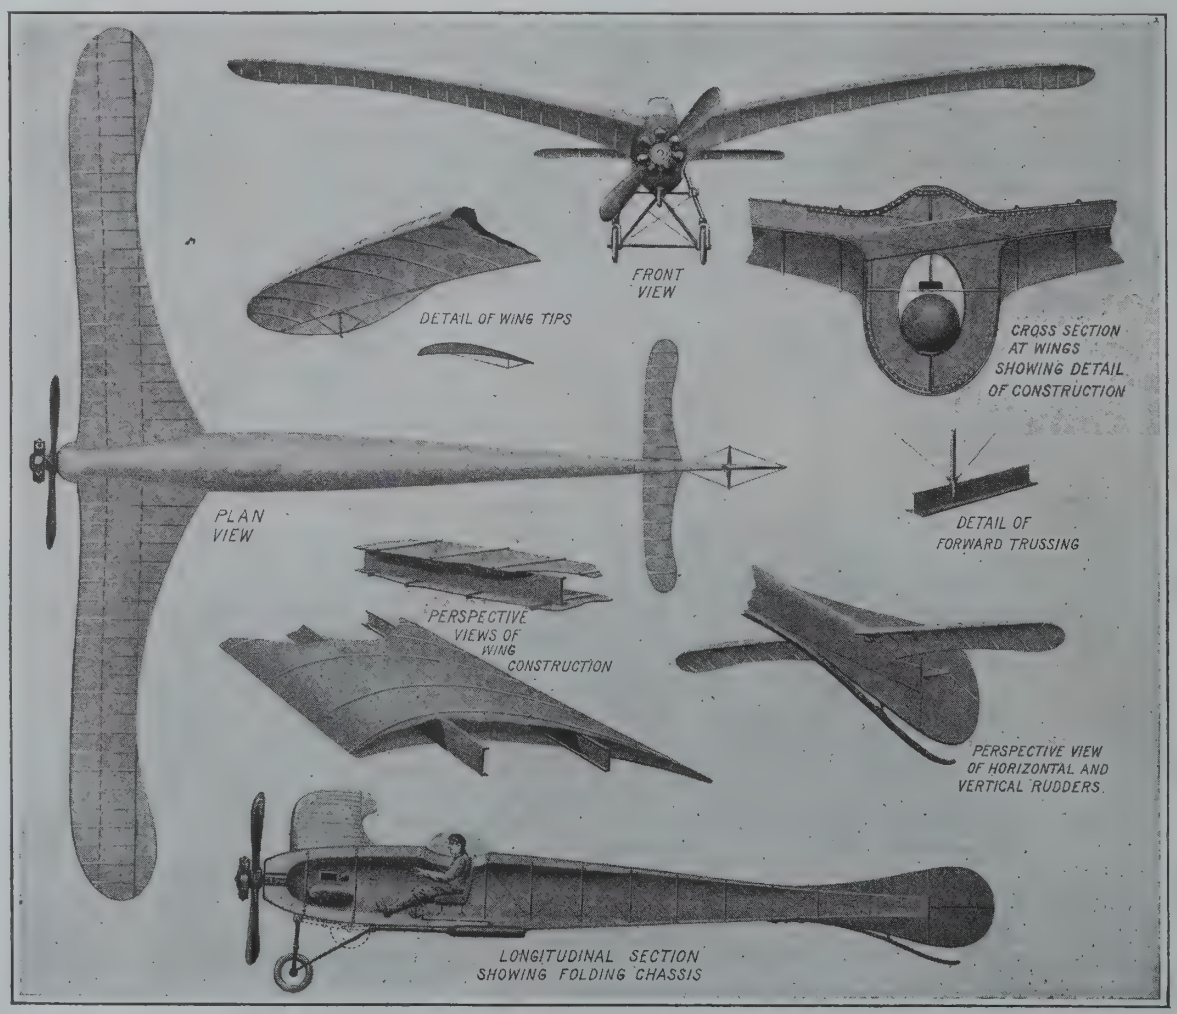
The principal resistances encountered by an airplane when in flight are those due to the lift and the head surface. The resistance due to the lift is fairly constant; for as the speed increases the angle of incidence decreases, and there is always an adjustment between the two which provides sufficient vertical reaction at all times to lift the weight of 500 to 1,000 pounds, as the case may be. The head resistance, however, increases approximately as the square of the speed; and if it is 100 pounds, say, at 40 miles per hour, it will rise to 400 pounds at 80 miles per hour. Hence the great importance, in a racing machine, of reducing the head surface to the least possible limit consistent with structural requirements.

It is the consideration of head resistance which has doomed the biplane as a purely racing type. When Octave Chanute built the first biplane glider, with its light, but very rigid Pratt trussing of vertical wooden struts and diagonal wire ties, he produced an excellent piece of engineering construction, which has proved to be ideally adapted to the early experimental stage which is now drawing to its close; but for high-speed results, because of the large amount of head surface presented, the Pratt truss was doomed to ultimate extinction. Unquestionably, the higher speeds which have been attained by the monoplane are due largely to the fact that its trussing is simpler, and the head surface, particularly of the wire stays, is relatively much less.

Now a word as to the resistance offered by a mass of tightly-strung wires. Professor Langley showed in his whirling-table experiments that the resistance of a wire is much greater than that which would be due to its projected area. As the speed increased, the resistance would rise rather quickly until, at a certain critical point, at which the wire would sing with a peculiar note, there was a sudden and very large jump in the resistance. This is explained by the fact that the rate of vibration of the wire under the rush of air is so great that it practically presents a solid surface, whose width is equal to the amplitude of vibration. Hence a tightly-strung wire presents a resistance to the air which is seemingly out of all proportion to its actual surface.

It follows, then, that even the simple king-pin trussing of the Blériot and Antoinette types must go if we are to achieve the high speeds which are predicted for the future racing machine. Now this will be possible only if some high-grade sheet metal is substituted for the canvas of the wing surface, and the necessary transverse bending strength is secured by means of plate-steel members enclosed within the wing surfaces and strongly riveted to the structure of the main body of the machine.

The form of wing shown in our drawings will afford a sufficiently strong construction in metal. The wings should widen considerably as they approach the body; for this would provide increasing space between the upper and under surfaces, and allow the depth of the channels to be increased proportionately to the bending stresses. These channels would be carried into the main body and riveted to transverse diaphragms, which should be so cut that the metal of the diaphragm would extend unbroken for some distance into the wings. We are convinced that by careful designing, the selection of the highest grades of steel, and by first-class workmanship, it will be possible to provide wings of ample strength without exceeding the limit of weight imposed by airplane requirements. Buckling in the fore and aft direction will be provided against by rolling the metal of the wing surfaces with shallow corrugations, as shown in the drawings. The main body of the airplane



**This sketch, showing the probable development of future airplane designs and construction, was originally published in the "Scientific American" of October 22, 1910**

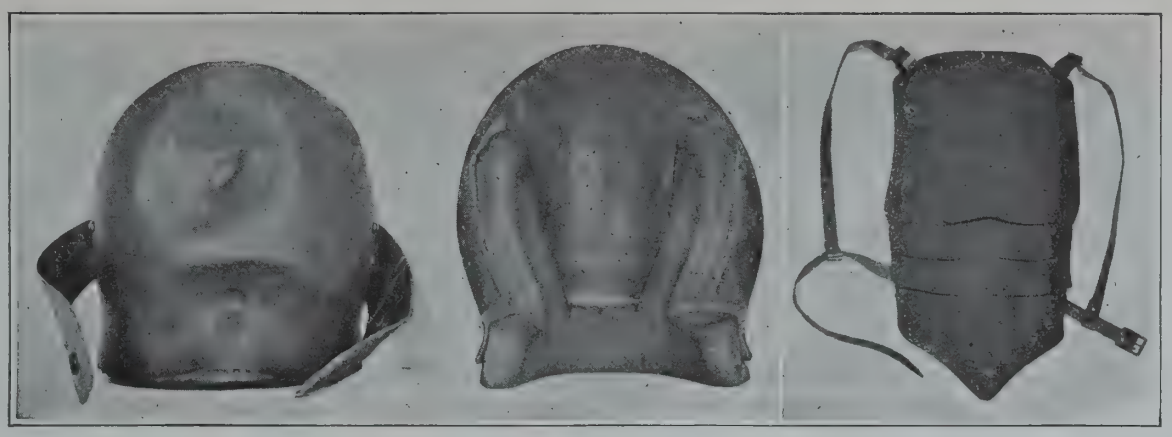
## Helmets and Body Armor in Modern Warfare

AMONG the many instances of a return to long-abandoned practice which were seen in the great war, was the universal adoption of the steel helmet and the tentative use of body armor. A work remarkable for its wealth of information has recently been written by Bashford Dean, Ph.D., Curator of Armor, Metropolitan Museum of Art, Major of Ordnance, in charge of Armor Unit, during the war. This book of 325 pages describes the various forms of armor designed and used for the American forces, and also discusses most entertainingly the helmets, body armor, et cetera, used by the principal nations engaged in the war. The work is most elaborately illustrated with line drawings and half-tones, and forms necessarily a most comprehensive, up-to-date work on this subject.



Experimental chin and face guard, front and rear views. Cushioned with sponge rubber

American laminated back plate of manganese steel. Stops 1000 f.s. bullet

In the years preceding the war, those of us who passed through the fine hall containing the Riggs Collection of armor at the Metropolitan Museum, regarded it as having an interest purely historical and artistic. Today we look upon those ancient and mediaeval forms with a new appreciation of their value. That armor could have been introduced during the late war and made effective, without loading down the soldier with an impossible burden, is due to the remarkable strides which have been made in the production of high-grade alloy steels of great resisting power in proportion to their weight. The bronze and other armor of the mediaeval times would not be effectual in stopping modern high-velocity bullets and shrapnel, but the manganese and other steels employed give to the modern soldier an immunity comparable to that enjoyed by the mediaeval armored knight against battle axe, sword and the swift-flying arrows of the Saxon bowmen.

We have selected a few illustrations from this volume which are characteristic of the several hundreds with which it is richly illustrated. Among these is a type of face guard, a device to accompany a helmet of the British type. This is an adaptation of the face guard of the fifteenth century. It encloses the face, rests on the chest and is held in position, not too tightly, by leather bands provided with snap fasteners. To absorb the shock of impact, the guard is provided with a lining of sponge rubber. This guard stopped the automatic revolver bullet at ten feet. A number were sent to the training camps and tried out and although the soldiers complained that it was a bit "stuffy," there can be no doubt of its value. That it is practical seems clear from the fact that the same form was in general use in Europe from 1450 to 1550.

We also reproduce the photograph of an experimental American body armor which consists of five pieces. The upper and larger portion covers the chest and stomach; to this are riveted two sections which protect the abdomen; below this, attached by leather straps and buckles, are two pieces of armor which afford protection to the upper part of the thighs. This armor is made of Baker's nickel-manganese alloy, and in the tests, at a distance of 200 yards, it served to stop a rifle ball fired with an initial velocity of 2,800 feet per second. With this may be compared the British body armor brought out in 1917-18. In its effort to furnish an improved type of body defense, the British Government, through its Munitions Inventions Board, manufactured the corselet which we illustrate. It weighs nine and one-half pounds and is formed of three elements—a breast plate, a back plate, and what is called a "sporran" piece. These are covered with khaki drill and are slightly padded. It will resist the ball of the automatic pistol, and also shrapnel and grenade. It will stop a bullet traveling at a rate of 1,280 feet per second. The plates are made of twelve per cent Hadfield's manganese steel of eighteen gage. This model was issued in pretty large quantities.

Between these samples of American and British armor we show an American model helmet which, if the war had continued, would probably have super-

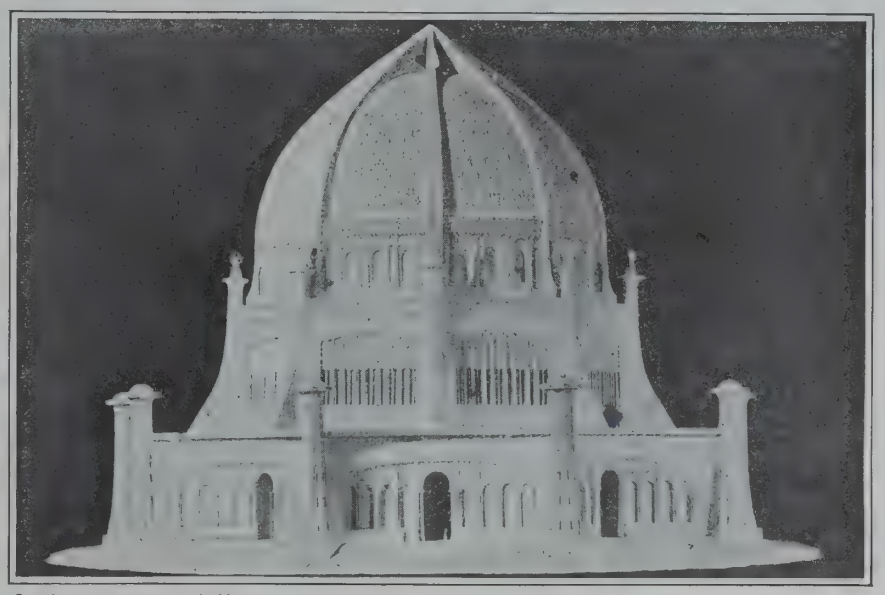
## Exotic Temples for Our Two Greatest Cities

A NEW religion, a new style of architecture—a style derived from astronomy, these are all things to animate the jaded mind after the war languor. A new religion coming from the East is a matter of course and hardly causes a ripple of either interest or enthusiasm; but the idea of a combination of religions or rather unity of nine which is unity in "spirit and in truth," is most extraordinary. Let us for the sake of argument have a religious "League of Nations" with the capitol in Persia, the chief promoter living in Palestine and the two great temples in Chicago and New York! This is an astounding proposition in itself, without considering for the moment the architectural setting for the two temples. We might as well tell the name of this new cult now as later—it is the "Bahai Movement," which, according to its devotees, is to weld together all the religions of the world in a common religious unity. The idea is common enough, and has been shaking the universe since the "Oxford" or "Tractarian" movement in the middle of the last century. It is the desire to gain unity without undue concession which animates all real inquirers.



Copyright by L. Bourgeois, Architect

An exotic Bahai Temple for the metropolis of the East and of the West

The Bahai movement assumes that there are nine of the great religions and that in a temple there should be nine sides with doors over which are inscribed a welcome in the language of the race to which the portal belongs. Within we are not to see nine pulpits with nine kinds of priests, rabbis, or exhorters in nine kinds of vestments or without them. The paraphernalia of religion is left out in the daylight, and in the dim religious light we have worship, music, and, above all, beauty. The effect produced on the visitor would be something akin to that wonderful Masonic Scottish Rite Hall in Washington where even the most hardened atheist and sinner would be softened by the combination of music and dim religious atmosphere. There is no other creed than the brotherhood of man and no other organization than a body of temple trustees who will govern the fabric.

The plans of the architect, Louis Bourgeois, differ somewhat in his earlier and later models, but our illustration suggests a compromise design which for real beauty is almost without a peer.

The architect has wrought into his decorations such symbols as the cross, the swastika, the five, six and nine-pointed stars. The use of vines, leaves and figures has been eschewed and purely mathematical lines have been substituted. The architect has derived his inspiration from the study of astronomy, for the overlapping curves which the planets trace in their different planes are very beautiful as they circle around in the heavens. The dome is the essential feature and somewhat suggests the so-called "Dome of the Rock" in Jerusalem, wrongly called the "Mosque of Omar." The external ribs are most pronounced, meeting in a Gothic point, suggesting hands clasped in prayer above the head.

The first story is Roman in its window arches, while the second is more Greek, and the next story suggests Chinese influence. In fact, it is a remarkable architectural blending. The building will cost several millions, but the result will be worth it.—By *A. A. Hopkins.*

**Tearing a piece of wrapping paper from a roll placed below the counter**

## Keeping the Wrapping Paper Out of the Way

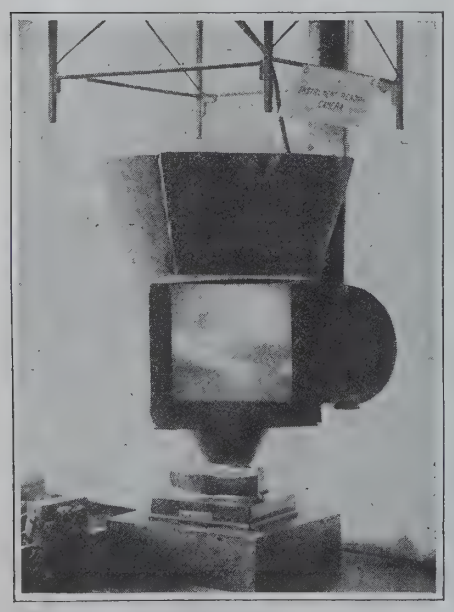
ONE of the latest aids to speeding up the wrapping of packages in stores and shops is shown in the accompanying illustration. It consists of a brass-lined slot in the counter top, through which protrudes the end of a roll of wrapping paper kept below the counter. When a piece of paper is wanted, the end is pulled until the desired length is attained, and by pulling the paper at an angle it is cleanly torn by the brass sides of the slot as shown. Not only does this arrangement save considerable room on the counter, but it is said to be considerably more convenient than the usual paper holder and cutter.

## Magnifying the Meter Scale for Better Readings

CENTRAL electrical stations and laboratories of public utility commissions, where rapidity and accuracy in testing of electrical apparatus are desirable, will find useful an instrument reading camera recently developed by the U. S. Bureau of Standards. The time element in testing instruments is appreciably reduced and only faults inherent in the electrical equipment are detected as errors. Any possible discrepancy of reading at the time of the test is virtually eliminated.

The scale of the instrument subjected to the test is brightly illuminated by a concentrated filament tungsten lamp and a system of mirrors and condensing lenses. Another lens and a right angle prism are mediums for flashing upon a ground-glass screen an image of the scale and pointer, magnified by five diameters. The enlargement of the object greatly reduces the possibility of error in reading the electrical instrument and when properly adjusted eliminates parallax error.

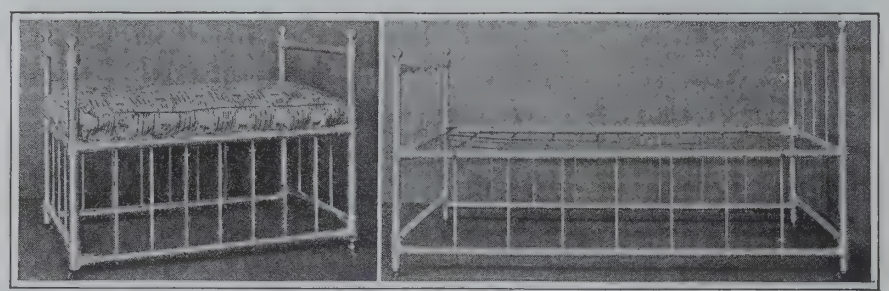
The reading camera is easily adapted to making observations from either vertical or horizontal scales. By the use of this device the results are more satisfactory as both eyes can be kept open and the head held in any convenient position. The reading camera is especially valuable in laboratories such as those maintained by central stations and public utility commissions where the position of a pointer over a scale is to be read rapidly and with considerable accuracy.



**This instrument shows up the meter reading in greatly magnified form for convenient reference**

## Furniture That Comes in Bundles

SOME ingenious Frenchman has invented a system of knock-down interchangeable unit furniture that is certainly unique and perhaps practical as well. The basis of this system is to be found in a collection of rods, tees, elbows and other fittings, which can be assembled in many different ways to form all sorts of furniture. The rods and fittings are bought in a store, and the purchaser then proceeds to make any desired bed or other piece of furniture within the limitations of the system. For instance, sufficient rods and fittings can be bought to make a small crib for the infant, and later, when the infant has grown to childhood, additional rods and fittings can be bought in order to enlarge the crib or even change it into a single bed or couch. The system also lends itself to making tables, settees, wardrobes and other furniture, although its prime purpose is for beds.



**Beds and settees of almost any size and design can be made from this ingenious system of rods and fittings**

## Machine-Made "Real" Lace

AN invention has just been patented for the manufacture of imitation "real" laces, by H. F. Soar, of Nottingham, which it is claimed will revolutionize the present methods of making imitation "real" laces. The inventor states that by the means of his invention, which is an attachment to an ordinary Levers lace machine, he can produce the lace the entire width of the machine, either in breadths from one inch upward or the full width of the machine for allover nets. Thus, a machine 100 inches wide could be made to produce 100 breadths of one inch, or 50 of two inch, and so on. Two sets of jacquards are used, one operating the warp threads and the other the bobbin threads.

The inventor considers that these machines can be worked by female labor, and that the laces could be produced cheaply. Hitherto imitation "real" laces have been made on the small, rapid, circular machine which weaves but two breadths.

## A Bicycle That Rides on Rails

RAILROAD inspection and repair work on a very modest scale are somewhat simplified by the introduction of a French invention which permits an ordinary bicycle to be ridden over railroad tracks in the manner shown in the accompanying illustration. The device consists of an attachment which serves to hold the bicycle squarely on one rail. The result is that the bicycle can be driven at a high rate of speed over the perfectly smooth surface formed by the rail. When the rider wishes to change from the railroad to an ordinary road, he merely detaches the simple framework, folds it up, and proceeds in the conventional manner by carrying the light framework along.

## Putting the Stove Chimney to Useful Work

THE fuel scarcity that prevails throughout most of Europe has aroused inventors to put forth their best efforts on the problem of securing new fuels on the one hand, and getting more heat out of old fuels on the other. A short while ago we presented in these columns an English invention for getting heat out of compressed sawdust. This time we present a French invention for getting more heat out of the conventional stove by changing the arrangement of the chimney.

The French call this latest invention the "spirale radiatrice," or heat-radiating spiral, so to speak. It consists of a stove chimney made in the form of a spiral and connected at either end with the usual chimney which passes through it. In actual operation the draft from the stove can be made to pass more or less through the spiral passage by means of suitable draft valves, in accordance with the requirements of the fire. The more draft passes through the spiral passageway the more heat is obtained from what would otherwise be wasted heat passing up through the chimney.

**This simple framework enables the railroad worker to ride a bicycle on the railroad tracks**

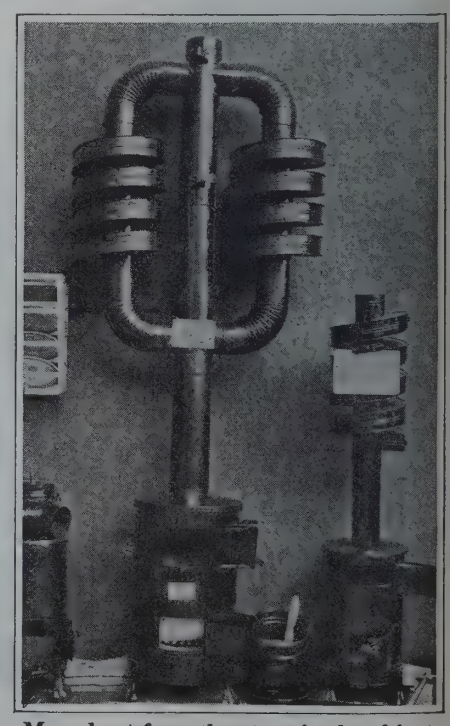
## Electrical Sterilization of Milk

A SPECIAL report has just been issued by the British Medical Research Committee, dealing with the destruction of bacteria in milk by electricity. In the introduction it is pointed out that the earliest description of an electrical method having this purpose in view was published by the Liverpool (England) Corporation in 1915, the investigator being Prof. J. Martin Beattie, of the University of Liverpool. Subsequently independent trials of the method were undertaken at Birmingham, and the opinion of the committee is that these latter experiments, while supporting the practical results obtained at Liverpool, did not entirely prove whether the electrical current in the method adopted had a directly bactericidal action or acted as a thermal agent. Sir Oliver Lodge inclined to the latter view.

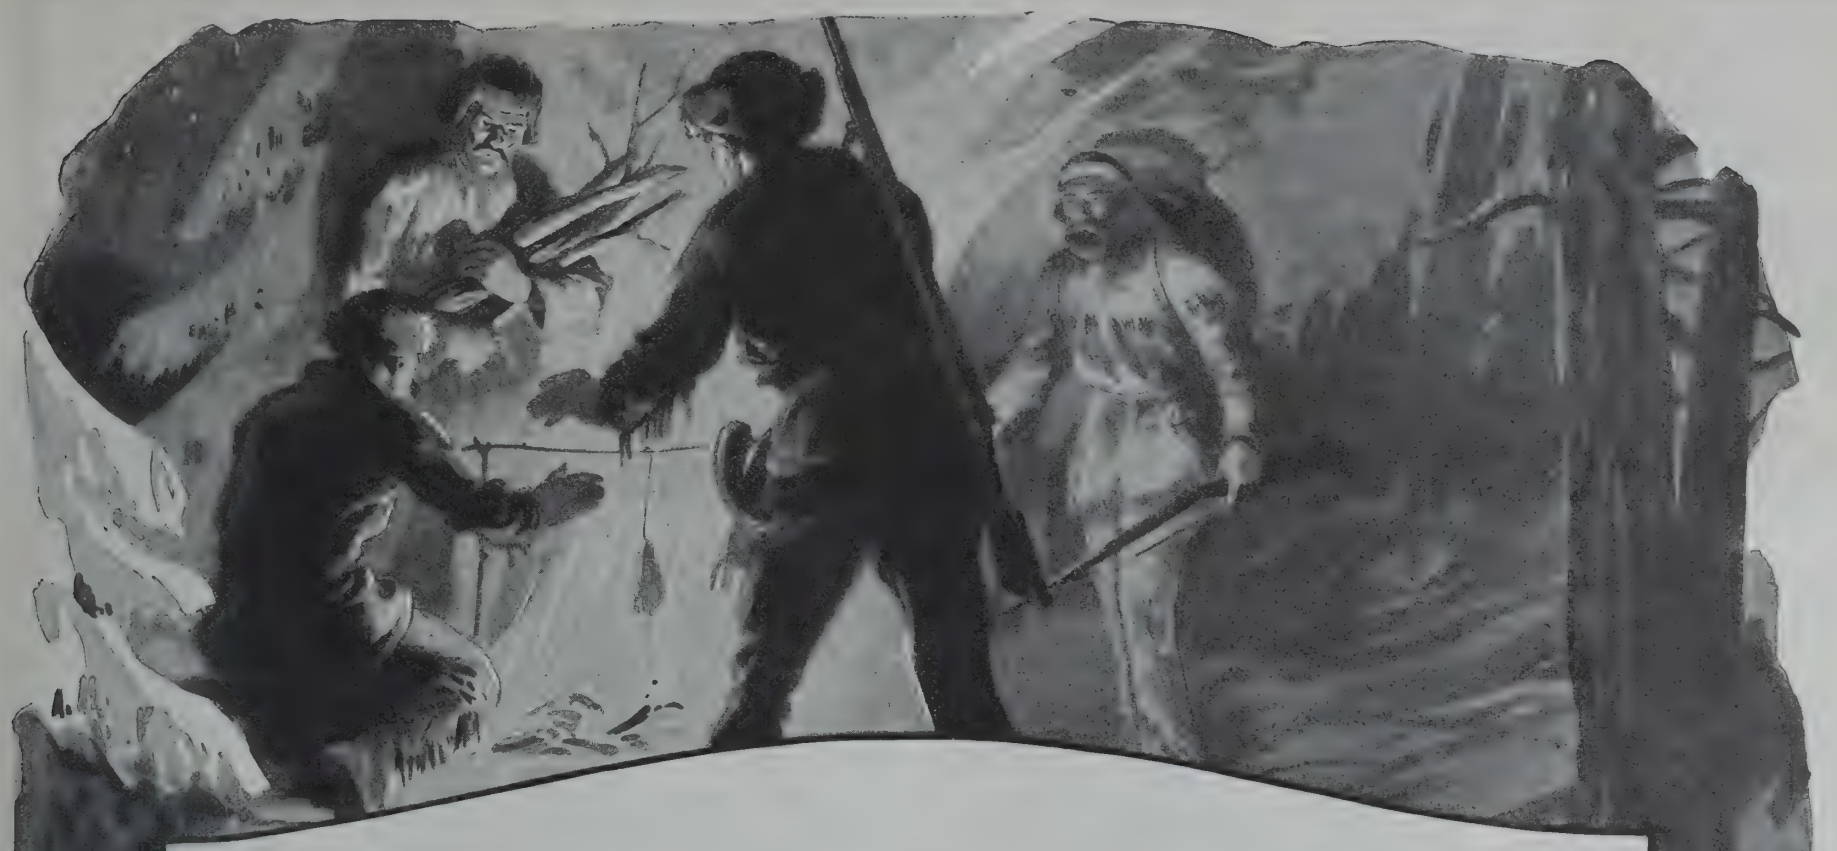
The report itself has been prepared by Professors Beattie and Lewis, both of Liverpool University, and enumerates the results of 15 experiments under varying conditions, with different degrees of current and with several qualities of milk, as well as showing two types of apparatus used. The final conclusions arrived at by the investigators are:

Milk can be rendered free from *B. coli* and *B. tuberculosis* by the new electrical method described without raising the temperature higher than 63° or 64°C. This temperature effect is very short in duration and in itself is not the principal factor in the destruction of the bacteria. Though the milk is not sterilized in the strict sense of the word, yet the percentage reduction of the bacteria taken over a period of a fortnight is 99.93. The keeping power of the milk is considerably increased.

The taste of the milk is not altered, and so far as careful chemical examination can determine the properties of the milk are not in any way impaired. The milk can accurately be described as "raw milk" free from bacteria.



**More heat from the stove is the object of these spiral draft chimneys**



# *Coal and Wood say, "Come to me for heat" Electricity says, "My heat is at your finger tips"*

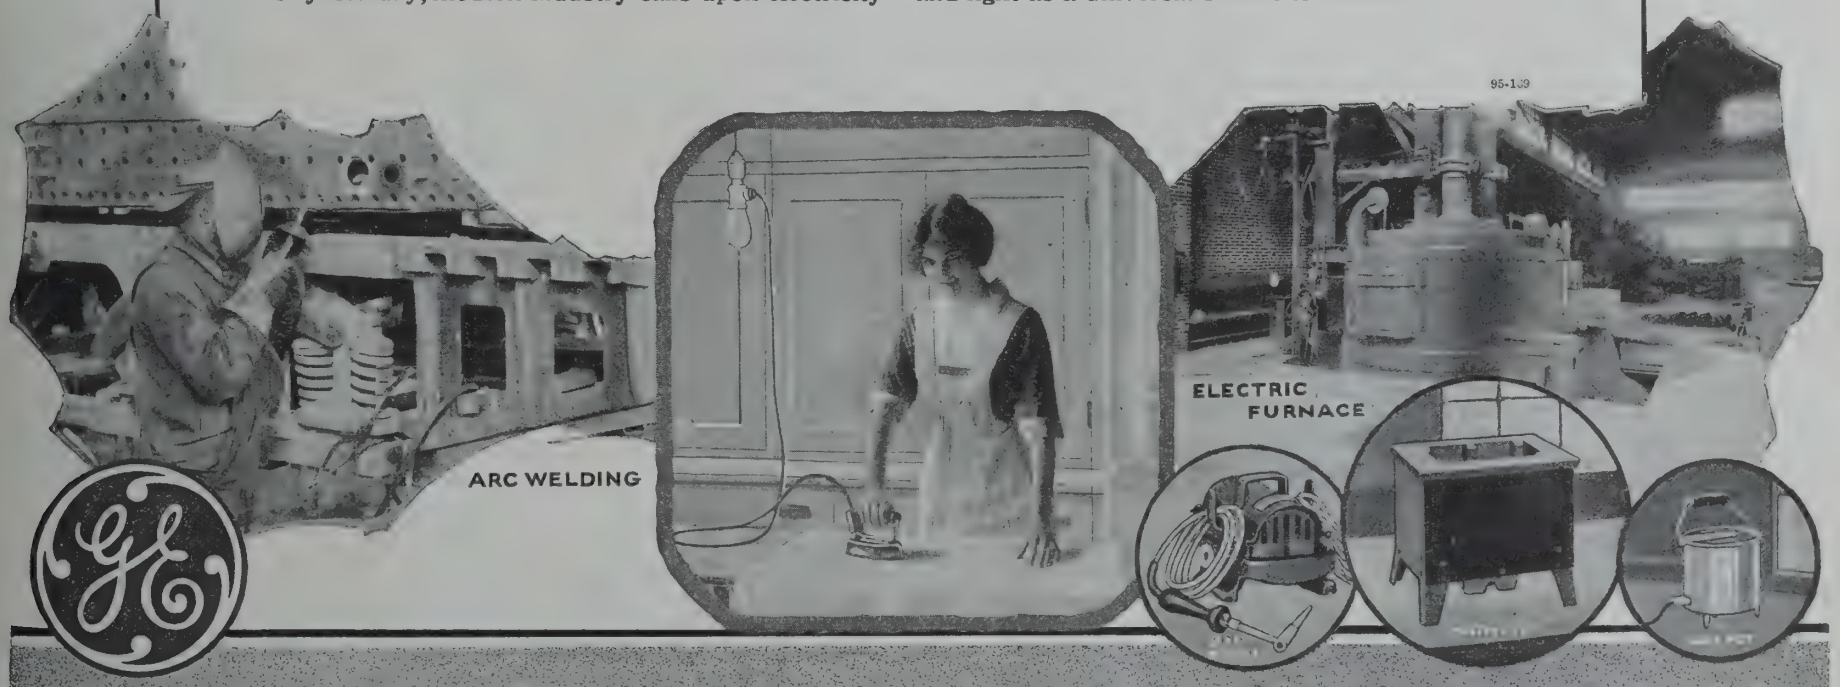
CAN you imagine a fire in Chicago and benefiting from its heat in New York? Yet that is what virtually happens in the case of electric heat. A current is generated, sent miles across country and converted into heat, wherever desired—instantly available, easily controlled and concentrated to the highest degree.

Domestic needs have produced the electric oven, cooker, broiler, toaster, flat iron, hair curler, percolator, glow heater and grill. These have eliminated drudgery, reduced fuel bills and fire risks, promote cleanliness and simplified housekeeping. In some states plentiful power from water sources and scarcity of fuel have made the heating of homes by electricity practical and economical.

In place of the grimy forge and the primitive bellows of yesterday, modern industry calls upon electricity to heat rivets, to alloy and temper metals, to weld and cut, to bake enamels and varnishes, and to perform speedily and more efficiently the thousand and one tasks that require heat. Electric furnaces, arc welders, glue pots, soldering irons, brazing machines—each one has the proper control to produce just the right amount of heat.

The broad utilization of electric heat has only begun. It has already called upon every resource of the General Electric Company: study, research, engineering and manufacturing.

While the problem of obtaining more power by connecting cities with far away water power and steam plants is being solved, the efficiency of the application of electric heat will also be studied so that electric heat may take its place with power and light as a universal benefit to mankind.



GENERAL ELECTRIC COMPANY

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

## Of Interest to Farmers

CULTIVATOR.—R. S. MATTINGLEY, Rockport, Ind. An important object of the invention is to provide a cultivator of the straddle-row type which may be readily and easily adapted to the cultivator of a great variety of crops and in which all of the subsidiary operations incidental to the use of the cultivator such as the adjustment of the cultivating or earth-working elements, the steering of the cultivator; the control of the draft, etc., may be efficiently carried out under the control of a single operator.

SHEAF DISTRIBUTER FOR THRESHERS.—R. B. MASON, 19 W. Patriot St., Somerset, Pa. The invention relates to distributing devices, more particularly to be used in connection with a thresher. An object is to provide a sheaf distributer for alining the sheaves and conveying them in an orderly manner to a thresher with which the distributer coöperates.

CONTAINER FOR SHEAF LOADERS.—R. B. MASON, 19 W. Patriot St., Somerset, Pa. One of the foremost objects of the invention is to provide a form of bottom for a sheaf container, which consists of a plurality of independently movable conveyers which can be separately actuated to shift the load into more advantageous positions. Another object is to provide a mechanically actuated gate cooperating with the movable bottom of the container, the gate being adjustable either high or low to regulate the quantity of sheaves discharged.

## Of General Interest

SQUEEZER.—S. E. CREASEY, Sanford, Me. The invention relates to juice extractors commonly known as "lemon squeezers," which may of course be used for other fruit. An object is to provide a device which is provided with an opening in the upper end of its ribbed or corrugated conical body portion to accommodate the core of the fruit, and which will also operate to cut the fibers connected to the core and thus expose the meat to the squeezing action against the surface of the core to thoroughly extract the juice.

BROOM.—T. A. VOSS, Phoenicia, N. Y. More particularly the invention relates to that class of brooms the sweeping or dusting portion of which is folded and retained in a binder by a retaining bar seamed in the ends of the binder. An object is to provide a device whereby old newspapers can be utilized for the sweeping element, by so constructing the broom head as to permit newspapers or other foldable sheet material to be quickly put in place to sweep and is readily removed for renewal.

HEEL FOR SHOES.—A. B. SCHAEFER, 140 W. 10th St., New York, N. Y. The invention relates more particularly to heels of the resilient type. The primary object is to provide a lift for heels which is readily detachable from the heel proper when the lift has become worn. A further object is to so construct the heel that it may be readily attached and detached so as to render unnecessary the services of a person skilled in the art of shoe manufacturing or repairing to carry out the operation.

PERFUME VIAL.—A. VERICEL, 315 W. 136th St., New York, N. Y. The invention relates to a method of disseminating perfume and the provision of a perfume vial. The desired evaporation of certain perfume oils may be obtained if minute particles thereof are exposed to contact with the air for evaporation. The object is to dispense the perfume without the use of alcohol; this is accomplished by providing capillary means through which the perfume oil passes to contact with the air.

FLOATING DEVICE.—G. JORDAHAN, Palm Beach, Fla. An object of the invention is to provide a device in the form of a life preserver wherein a proper supporting member is provided when wanted and a light package when not wanted. Another object is to provide a device which may be tied around the body or fastened in a number of ways without effecting its usefulness, and which may be folded into a minimum sized package when not in use.

SELF-OPENING CONTAINER.—C. GUERITEY, address C. S. Humphrey, c/o Manhattan Can Co., Bush Terminal Bldg., No. 10, Brooklyn, N. Y. The invention relates more particularly to a container which is air-tight and adapted to be self-opening. Among the objects is to provide a container having a cover and a main body portion which is simple in construction, economical to manufacture and which may be opened without requiring the use of instruments or other means for separating except merely dropping the box suddenly. The box is particularly adapted to receive paste or other semi-liquid material.

WOODEN SHOE OR SANDAL.—P. DEMARMELS and A. WINKLER, 161 Avenue B, New York, N. Y. The object of this invention is to provide a wooden shoe or sandal having a wooden sole made in sections hinged together to provide a desired flexibility and thus to insure ease and comfort in walking. Another object is to conceal the hinges connecting the sole sections to prevent the corroding influences such as moisture, water, acids and the like from reaching and injuring the hinges.

RIMMED EYEGLASSES AND SPECTACLES.—S. GOLDFADEN, 609 W. 114th St., New York, N. Y. The invention relates to eyeglasses having rims of shell, celluloid or other similar material. The object is to provide rimmed glasses and spectacles whereby an optician is enabled to quickly and conveniently fit any one of the many types of bridges or temples to the rims as desired by a customer, and to permit the optician to conveniently place the lenses in position in the rims without requiring heating thereof.

FALSE BOTTOM FOR GARBAGE RECEPTACLES.—C. J. JACOBSSON, c/o M. Rock, 315 5th Ave., New York, N. Y. The object of the invention is to provide a false bottom of paper or similar cheap material for garbage cans and similar receptacles used in households, restaurants and other establishments, and arranged to maintain the receptacle in a sanitary condition when emptying it of its contents, especially protecting the bottom of the receptacle against adherence of moisture, fats and like matter.

COVER REMOVER.—A. S. MORANGE, 129 King St., Northampton, Mass. This invention relates to cover removers and has reference more particularly to a cover remover provided with means adapted to first cut the label on a can and then lift the cover with a wedging action. Another object is to provide a cover remover especially adapted for removing the covers of cans without spilling the contents thereof or damaging the cover.

COFFEE URN.—A. M. SALAZAR, 108 W. 44th St., New York, N. Y. The primary object of the invention is to so arrange the process of making coffee that the ordinary coffee urns commonly used in restaurants and like places may be eliminated and the liquid coffee made direct from the water boiler generally employed in restaurant kitchens. A further object is to provide a device in which various quantities of coffee may be brewed at a single operation.

ROLL-FILM CARRIER.—O. C. HUMMEL, Box 86, R.F.D., No. 2, Nauvoo, Ill. An object of the invention is to provide a neat carrying case for containers of roll films in which a number of containers for film rolls may be carried and protected from the weather and in which means is provided for inserting containers having exposed films at the bottom of the carrier and for removing containers having unexposed films at the top.

SHOE STRETCHER.—H. WATERS, Box 182, Bisbee, Ariz. The object of this invention is to provide a device by means of which the shoe may be stretched in many directions either longitudinally or laterally at different points or in a vertical direction; a stretcher plate is provided which may be set in place at the point where it is desired to stretch the shoe.

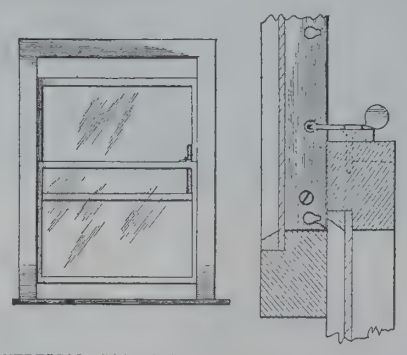
SELF-RAISING LID FOR ICE-CREAM CABINETS.—C. R. RAGSDALE, c/o Liquid Carbonic Co., 539 Magazine St., New Orleans, La. The general object of this invention is to provide a lid of the indicated character provided with means whereby to automatically throw the lid to the raised position whenever the latch means releases the lid. More specifically the object is to provide an embodiment of a simple and durable form as well as convenient to install.

OIL CAN.—J. H. HALL and W. B. HAMILTON, Rupert, Ida. This invention has for its object to provide an oil can having means for permitting the oil to be forced from the can in spurts or in a steady stream by grasping the can between the thumb and the first two fingers and making pressure with the thumb toward the fingers with the can so held.

ROOFING.—R. W. BLANTON, Ironton, Ohio. The invention relates to sheet metal roofing. The object is to provide lock-joint metal roofing sheets of such formation that not only can successive sheets of one course be interlocked, but successive courses can be lapped over each other, the lock-joints of one course coming substantially in the middle of the sheets of the course below, thereby staggering the lock-joints and forming what is known in the art as a "break joint" construction. A further object is to provide lock joints which will not become separated by expansion and contraction under the influence of heat and cold.

## Hardware and Tools

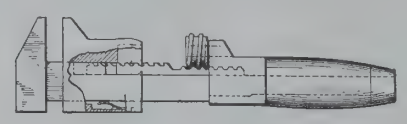
WINDOW LOCK.—R. BELLINGER, 226 E. Main St., Chicopee Falls, Mass. The object of the invention is to provide a window locking device which will lock a window in closed position or in any of several open positions so as to secure ventilation at the top or bottom of the window or both, the device when in



A VERTICAL SECTION OF THE DEVICE AND CONVENTIONAL FORM OF WINDOW WITH DEVICE APPLIED

locking position preventing rattling of the window. The lower sash is provided on its upper edge with a locking member which co-acts with a keeper secured to the upper sash for locking both the sashes against movement relatively.

WRENCH.—H. B. WINTER, County National Bank Bldg., Punxsutawney, Pa. This invention has for its object to provide a wrench wherein a fixed jaw is provided with a movable jaw adjustable toward and from the fixed

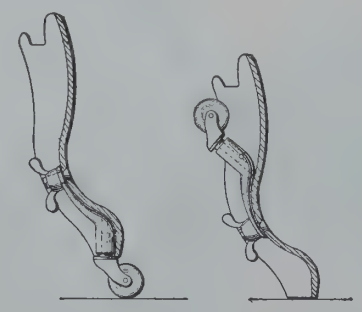


A SIDE VIEW WITH PARTS BROKEN AWAY

jaw with a coarse and a fine adjustment, the said adjustments being independent of each other. In order to attain the coarse adjustment the movable jaw is tilted and moved toward the fixed jaw to engage the object; when so engaged the fine adjustment may be attained by means of a worm.

## Heating and Lighting

CASTER ATTACHMENT FOR STOVE LEGS.—J. O. SABOM, 616 Tower Ave., Superior, Wis. A purpose of the invention is to provide an attachment for supporting a caster on a stove leg in such manner that the caster



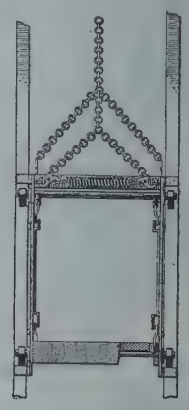
SHOWING THE ATTACHMENT IN ACTIVE AND IN INACTIVE POSITIONS

will extend below and support the leg to facilitate the movement of the stove from place to place, but the caster is capable of being moved to an inactive position after the stove has been moved and will function as before to prevent accidental movement of the stove.

HEATER FOR WASHING MACHINES.—H. S. CARSON, 139 Prospect St., Stamford, Conn. The invention relates to a heater which is more particularly applicable to washing machines, and aims to provide a device wherein the soapy water usually wasted may be heated again and reused; means are associated with the heater for maintaining the fluid at a proper temperature. A further object is to associate the heater with the washing machine in such manner that the fluid may be drained from the heater into the washing machine, or vice versa.

## Machines and Mechanical Devices

SAFETY DEVICE FOR ELEVATORS.—L. COURTY, Windsor, Mo. An object of the invention is to provide a simple and durable safety device for elevators in which the elevator will



FRONT ELEVATION OF ELEVATOR EQUIPPED WITH THE DEVICE

be securely and positively locked to the guide rails when the supporting cable does not serve to support the elevator or breaks, or whenever the elevator is in danger of falling irrespective of its position in the elevator shaft.

HEDDLE.—H. RUEGG, JR., 12 Kingswood, Weehawken, N. J. The inventor has been granted two patents relating to heddles for looms. The objects are to provide a heddle arranged to permit the weaver to readily engage a warp thread with the eye of the heddle without the use of a hook or similar tool. Another object is to prevent the warp thread from passing accidently out of the eye on raising and lowering of the heddle. A still further object is to permit of making the heddle of one single strip of metal or other material.

CUTTING AND ROUNDING-OFF MACHINE FOR TEETH FOR CLOCKS.—F. L. W. BUCKMANN, Amsterdam, Holland, Netherlands. This invention relates to a machine for cutting and rounding off the teeth on spur and bevel toothed wheels and pinions for the clock work and instrument makers' trade; an object is to make the machine very simple and compact in order that it can be easily handled in the clockwork makers' and instrument makers' trade.

EQUIPMENT FOR MOVING PICTURE MACHINES.—R. N. VYNE, c/o Vyne Bros. Electric Co., Reif Bldg., Prescott, Ariz. The object of the invention is to provide equipments for moving picture machines whereby a shutter is interposed between the distant screen and the source of light of the corresponding moving picture projecting machine used at the time with a view to prevent the undesirable red afterglow appearing on the distant screen on stopping the projecting machine. Another object is to keep one shutter of the non-active machine closed while the other shutter for the machine in use is open.

LIQUID MEASURING DEVICE.—J. D. MEREDITH, 60412 8th St., Wichita Falls, Tex. More particularly the invention relates to liquid measuring devices for dispensing gasoline, oil and the like. An object is to provide a device which will actually indicate both to the buyer and seller the amount of liquid dispensed. A further object is to provide means which will permit the buyer to see the condition of the gasoline before it is delivered from the machine.

FUR SCREEN.—T. TRAVIS, c/o Knox Hat Co., Grand Ave., Brooklyn, N. Y. This invention relates to screens for receiving fur from felt pad forming machinery, and has for an object to provide a construction which will continuously operate and thereby obviate the necessity of shutting down at any time. A still further object is to provide a screen whereby air may keep the screen clean and at the same time escape as the fur matter passes a receiving container.

PUMP.—H. JACKSON, 1633 E. 13th St., Brooklyn, N. Y. The invention relates to a pump which is peculiarly adaptable to the

(*Continued on page 164*)

# Organization—Equipment—Knowing-how Produces the new Leland-built Motor Car

In this day of big things, what more magic words than these: 'Organization,' 'Equipment,' 'Knowing-how?'

Without them is nothing great accomplished.

With them, nothing seems impossible.

Many are the stories of vast achievement in the world mechanical; among them is a story not widely known, yet a story for whose parallel you would seek far to find.

In order to understand the possibility of that achievement, let us hark back some thirty to forty years.

Then, Henry M. Leland was a conspicuous figure, in New England's higher craftsmanship.

Some years before, he had left his boyhood home on the farm in Vermont, and gone to Worcester, Mass., where he engaged as an apprentice. He became a workman at the bench, but not for long, because he soon compelled recognition as an artisan of an uncommon kind. He showed an ability to do things— to do them differently, and to do them better than they had been done before.

He became a machinery salesman, and an unusual one, because he was more than a salesman.

He knew, too, how to install and to teach the operating of the machines he sold.

Manufacturers sought his counsel. They engaged him to re-organize their equipment and their men.

He knew how to increase production, not by oppressive, but by progressive methods. He did two more things, which to those who do not know him and his methods, may seem anomalous or impossible — yet he did them.

Besides increasing volume, he actually reduced production costs, and at the same time bettered infinitely the quality of the things produced.

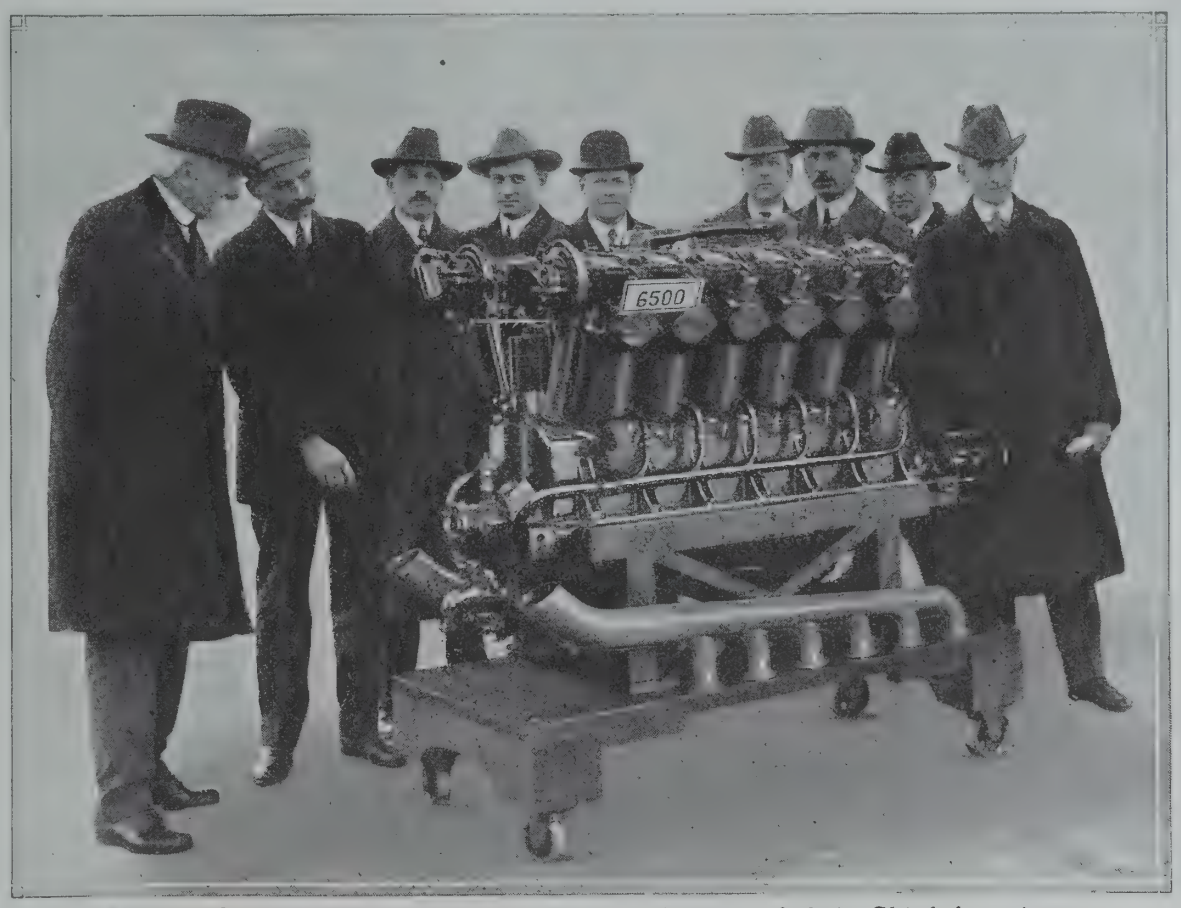
He had a knack and a penchant for doing things while others were saying they could not be done. His was supreme delight to bring order out of chaos.

Many are the great establishments today which owe the foundation of their prestige and their success largely to the organizing, producing and quality-building genius of Henry M. Leland.

He is credited with a multitude of 'crowning achievements,' because he has made it a life principle always to do things better than they had been done before.

His generalship in organization is strikingly exemplified in that of the Lincoln Motor Co., although he maintains that Wilfred C. Leland who has been his mainstay and close associate for many years, assumed a large share of the responsibilities; and to its success he also attributes the loyal, skillful and effective co-operation of his thousands of other associates.

In the year 1890 the Lelands came from New England to Detroit, where for a number of years they engaged in the manufacture of the finer kinds of machinery and precision tools. They were among the pioneers in the making of gasoline marine and automobile engines; and after eighteen years, many of those engines are still in service—a tribute to the Leland ways of doing.



*Henry M. Leland, Wilfred C. Leeland and some of their Chief Associates, viewing the 6,500th Lincoln Liberty Aircraft Motor*

*Of these nine men, seven have been in continual relation for 12 years; five for 21 years and three for 27 years*

***A Duplicate of this Motor is now in the Smithsonian Institution at Washington, D. C., where it will stand for all Time, a Monument to and an Example of the world's finer Craftsmanship***

Shortly after our country became involved in the world conflict, the vital need for aircraft so forcibly impressed itself upon the Lelands that they severed their many years' affiliation with the motor car industry, in order that they might undertake the production of Liberty airplane motors for the allied fighting forces. This they did in July, 1917.

With absolutely nothing in the way of plant or equipment, they received the government's first award for the building of these motors—and faith in the men and their ability was the government's sole assurance.

Capital was interested, and much volunteered. The Lincoln Motor Co. was formed. Fifty-two acres of land were acquired. An adequate plant was erected and equipped in record time. A vast amount of machinery was designed, built and installed. Tools to the extent of 6,522 separate and distinct designs, aggregating 91,807 in number were made.

Thousands of America's most skilled craftsmen tendered their co-operation and their services. Many of the men, particularly the executives, were men whom the Lelands knew and who knew them, through many years' association; and they were anxious to enlist under their banner.

Never in their lives, say the Lelands, have they seen such a vast organization get into working harmony with so little delay and so little friction.

The efficiency of that organization can best be appreciated when it is realized that in seven months and three days after starting with nothing, they assembled their first motor. In ten months thereafter, and with 6,000 employees, the Lincoln Motor Co. was producing at the rate of 50 motors per day. In contrast with these Leland methods, the leading English manufacturer, with three years' aircraft experience and 10,000 employees, had required a week to produce the quantity of motors which the Lincoln organization had produced in a single day.

Within eleven months from the day production of completed motors began, the Lincoln Motor Co. had established the record of producing the largest number of motors in a day, the largest number in a month and the largest total produced by any manufacturer from the beginning; and those who know the story of Liberty motor building know the rivalry for that record.

The quality of Leland-built Lincoln Liberty motors has been attested by tributes and in ways which could not be misunderstood; and, too, the Lincoln Motor Co. was able to render assistance of immeasurable value to those less favorably schooled.

Assembling and harmonizing an organization expeditiously, for doing things in a big way and doing them right, is, like everything else—no matter how difficult it may seem—a plain, simple matter of 'knowing how.'

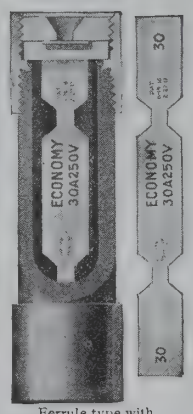
This is simplified when the executive and his chief assistants in things mechanical can go into the shops, and with their own hands perform practically every task and operation, from the ground work to the finished product.

Such is the skill and genius; such is the organization that is producing the new Leland-built car —the car destined to chart the future course of fine car making—the car destined to prove another 'crowning achievement'—the car destined once more to demonstrate Leland determination and Leland ability to surpass.

LINCOLN MOTOR COMPANY DETROIT, MICHIGAN

## You Buy the Highest Type of Electrical Protection

in any circuit when you install Economy Renewable Fuses—made in both ferrule and knife blade types in all capacities.



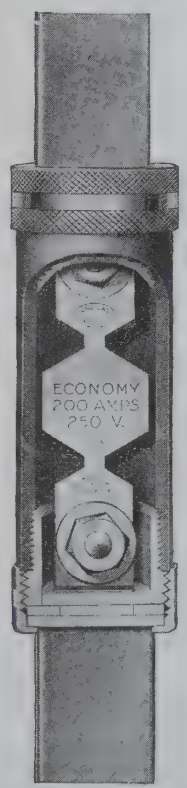
Ferrule type with Economy "Drop-Out" Renewal link

Accurate rating, practical, safe fuse construction and a dependability which has been proved for years in thousands of industries, large and small, make Economy Fuses first choice where efficiency is the first consideration.

# ECONOMY *renewable* FUSES

## And You Cut Fuse Maintenance Cost 80%

compared with the maintenance cost of any "one time" fuse equipment.



Knife-blade type with Economy "Drop-Out" Renewal link

Only the "Drop Out" Renewal Link is destroyed when the fuse blows.

Both ferrule and knife-blade types are easily and quickly restored without expensive delay in service.

**Economy was the first line using inexpensive bare renewal links for restoring blown fuses to their original efficiency to be APPROVED IN ALL CAPACITIES by the Underwriters' Laboratories.**

***Sold by all leading electrical jobbers and dealers***

**Economy Fuse & Mfg. Co.**
**Chicago, U. S. A.**

Economy Fuses are also made in Canada at Montreal

## RECENTLY PATENTED INVENTIONS

(*Continued from page 162*)

pumping of fluids, such as oil, water and gasoline although the same may be used for any fluid. Among the objects is the provision of a single valve which will present two separate pistons, so that all parts such as springs, etc., may be eliminated, a tight seal formed within the pump, a bearing which will efficiently lubricate the moving parts and to so construct the pump that it is impossible for the most unskilled laborer to apply the same improperly.

FIREPROOF FILM REEL.—W. RICE, 88 Cumberland St., Brooklyn, N. Y. The invention aims to provide a film reel which shall be entirely fireproof so that no possibility of an explosion occurring in the operator's booth. A further object is the provision of a film reel in which a film may be transported and be guarded against any accident, the end of the film readily attached to the securing means, and the provision of a structure which will make it possible to have free access to the interior of the reel at any time necessary.

CLOTH LAYING MACHINE.—M. ISAACS, 15 E. 17th St., New York, N. Y. The invention relates to a machine for piling cloth on the cutting tables in factories preparatory to marking and cutting. Among the principal objects are, to simplify the operation of the machine, to reduce the cost of construction, and to insure accuracy when piling the same on a table.

ATTACHMENT FOR TYPEWRITERS.—F. E. FANGER, Apartado 5138, Mexico, Mex. This invention relates to an attachment for typewriters whereby the user may know at any time and instantly how many lines may still be written on the unused portion of the paper inserted in the machine. The general object is to provide an indicating attachment which may be readily applied to standard typewriter machines in use or embodied in the machine at the factory.

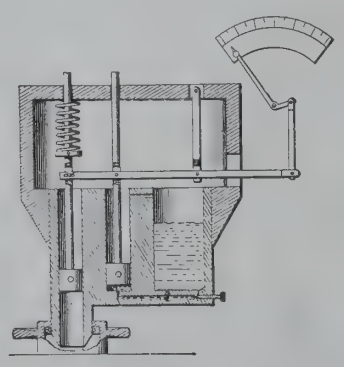
INDICATOR VALVE POST.—R. H. THORNE and F. J. MILLER, Williamsport, Pa. An object of the invention is to provide an indicator valve post wherein one legend bearing plate may be adjusted with respect to the other so that but one valve operating screw of the same pitch need be employed irrespective of the diameter of the valve in any of a number of indicator posts wherein the invention may be embodied.

### Musical Devices

PHONOGRAPH ATTACHMENT.—D. MCNEILL, Huntington, W. Va. The particular object of this invention is to suppress as far as possible the undesirable noises due to the mechanical scratching of the stylus upon the record disk or member equivalent thereto by dividing the sound waves into two parallel channels so arranged as to cause the undesirable sounds passing through one channel to interfere with those passing through the other and to neutralize to a considerable extent the acoustical effect of the two groups.

### Prime Movers and Their Accessories

PRESSURE INDICATOR.—M. R. BUCHANAN, Silver City, N. M. This invention has for its object to provide an indicator of the character specified especially adapted for indicating the mean effective pressure in the cylinder

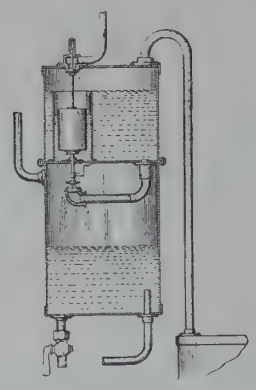


A SECTIONAL VIEW OF THE INDICATOR

of an internal combustion engine and to indicate the load that each cylinder is carrying in multiple cylinder engines to permit the load to be evenly balanced between the cylinders of the engine.

HYDROCARBON BURNER.—K. A. STAHLGREN, 131 Broadway, Newport, R. I. The object of the invention is to provide a hydrocarbon burner arranged to insure a thorough atomizing of the crude oil or other liquid hydrocarbon fuel, and to produce an effective mixing of the air and the atomized fuel to insure complete combustion thereby utilizing the liquid fuel to the fullest advantage. Another object is to insure the formation of a conical-shaped flame.

FUEL SUPPLY SYSTEM.—M. PARNES, 231 2nd Ave., New York, N. Y. This invention relates to fuel systems for internal combustion engines and it pertains more particularly to that type of system in which the operation is carried out by means of a partial vacuum.



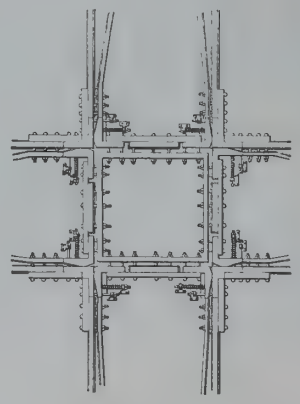
A VIEW WITH THE PARTS IN POSITION WHEN VACUUM IS CUT OFF

It is the prime object of the invention to supply the auxiliary receptacle with fuel from the main receptacle automatically by the creation of a partial vacuum within the auxiliary receptacle.

### Railways and Their Accessories

MEANS FOR PREVENTING CLOGGING OF SAND PIPES.—G. H. JOHNSON, address J. L. Taylor, Gulfport, Miss. The invention relates generally to sand pipes of steam as well as street railways, the primary object being the provision of simple inexpensive means to prevent the clogging of sand pipes, particularly at or adjacent to the discharge end of the pipe, where clogging commonly occurs. Another object is to provide an air supply attachment under control of the operator, to direct the sand exactly where it is desired in spite of the influence of the wind or other exterior force.

RAILROAD CROSSING.—J. P. HOUK, New Albany, Miss. This invention has for its object to provide a crossing wherein the shock and jar of the wheels crossing the space between the rails is eliminated, a bridge being



A PLAN VIEW OF THE CROSSING

provided normally spring held in position to support the crossing wheels, but arranged to be moved out of the way of a wheel coming at right angles.

### Pertaining to Recreation

TOY BAND WAGON.—C. H. BALKNAP, 323 Washington St., Brooklyn, N. Y. The object of the invention is to provide a toy wherein a combined wagon and music box is provided, arranged to operate independently or simultaneously. Another object is to provide a toy wagon provided with a talking machine and means for connecting the talking machine and wheels of the band wagon with the same driving motor.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## Reducing Trade Routes with Submarine Freighters

(*Continued from page 150*)

nevertheless be structurally so molded that she could sustain the hydrostatic pressure at a depth of 600 feet. The intention, however, is to restrict diving under working conditions to a maximum depth of not more than 300 feet. According to his calculations, Mr. Lake believes that he can build a ship of his special pattern with less material than the usual surface freighter of equal strength and carrying capacity, and he is convinced that his submarine would be cheaper to operate. Of course, his saving in structural weight is due to his adoption of a circular cross section wherever possible and in limiting to a marked degree the extent and mass of the steel work above water.

With her ballast tanks empty, the ship would have a displacement of about 9,000 tons, and the difference between this and the submerged displacement—4,000 tons—would represent reserve of buoyancy. This could be called into play to enable the boat to rise up through the ice by centering this effort along the rather narrow edges of the craft's "hog back." That is to say, it will be possible to drain the ballast tanks at a depth of 50 feet; and this suddenly applied buoyancy would produce an upward impulse of sufficient moment to lift and to shatter the ice in a direction in which it is least capable of resisting fracture. The upper line of the ridge or deck will be reinforced by a heavy steel rib, and this rib will merge with a very strong conning tower so shaped forward and aft that the ends will, in effect, constitute powerful ploughshares. Therefore, rotten ice or ice several feet thick can be broken and turned aside in a way to clear a channel for the conning tower to forge through. By inclining the bow slightly, with the submarine running at the surface in the awash condition, and then driving ahead, much of the ice encountered during the spring and summer can be smashed and scattered without resorting to total submergence. In this trim, the submergible freighter will remain in contact with the air and be able to use her main propelling plant, be that a steam or a Diesel engine. Mr. Lake is of the opinion that it would probably be unnecessary to submerge entirely except on rare occasions.

The scheme is not to provide short routes only between existing deep-sea ports. The aim is to open up to commerce regions that are now rather inaccessible and yet susceptible of contributing enormously to our stocks of raw materials, etc. For instance, northern Russia and Siberia cover an immense area rich in gold, silver, platinum, iron, coal, timber, and furs; and a portion of this part of the world is capable of yielding yearly many millions of bushels of wheat. There are three great rivers, each a good deal longer than the Mississippi, which drain this area and empty into the Arctic Ocean, where shipping points could be established.

Again, to bring the benefits nearer home, Mr. Lake proposes to use submergible freighters to tap northern Canada so as to provide a ready outlet for the wheat and other commodities of Manitoba and Saskatchewan. He would do this by way of Hudson Bay, which is usually open about six months a year, and thus save more than a thousand miles of the journey which these products have to make in reaching the Great Lakes and thence to the seaboard en route to Liverpool. Conditions in Hudson Bay which would be likely to interfere with or halt transportation in the usual types of steamers would not prevent the effective operating of cargo-carrying submarines. Each ship of the size already mentioned would be able to handle a load of 7,500 tons.

# UNDARK Radium Luminous Material

**UNDARK is used on numerous articles, of which the following are the most important**

| | |
|---|---|
| Watches | Gasoline Gauges |
| Clocks | Speedometers |
| Flashlights | Steam and Pressure Gauges |
| Pull-Chain Pendants | Revolver Sights |
| Push-Button Switches | Telephone Mouthpiece |
| Flip Switches | Fire Extinguishers |
| Door Bells | Mine Signs |
| House Numbers | Women's Felt Slippers |
| Hospital Call Bells | Fish Bait |
| Ship's Compasses | Theatre Seat Numbers |
| Locks | Convention Buttons |
| Safe Combinations | Poison Indicators |

**Names of the makers of these furnished upon request**

## *"I want that on mine"*

If the number on your front door glows in the dark with UNDARK, people can tell if it's the house they want without lighting matches or ringing your bell to inquire.

UNDARK will make your house number visible twenty-four hours daily just as it makes watch dials readable in the dark.

### UNDARK doesn't get dark in the dark

You want UNDARK, because it contains real radium and keeps its glow for years..

We are miners and refiners of radium-bearing ore, the pioneer manufacturers of radium luminous material in this country, and the largest in the world.

If you are interested in seeing how UNDARK can be applied, we will send you a TRY-OUT set for $3.00. In writing, state class of work for which you want to use it. We can also give you the names of manufacturers who use UNDARK on the particular articles in which you are interested.

*UNDARK can be successfully applied by manufacturers in their own plants. It is a simple process. We will instruct operators and organize the work for you. Write for details.*

## Reducing Trade Routes with Submarine Freighters

(*Continued from page 164*)

As Mr. Lake sees it, the under-water ship of trade has claims to consideration even beyond its peculiar fitness to navigate ice-strewn waters. He declares his submersible to be safer to run at all times and that it is practically unsinkable except at the will of those aboard. Despite the fanciful character of the project, it should be borne in mind that Mr. Lake has helped materially toward achievements commonly believed Utopian twenty-five years ago; and it is upon these accomplishments that he now confidently bases his contemplated revolution in deep-sea transportation.

## The Aquitania as an Oil Burner

(*Continued from page 151*)

in each watch, and the loss from this cause amounted to 8,000 horse-power every 4 hours. With oil firing there is a constant flow of oil; a constant furnace temperature; and contraction stresses, due to the inrush of cold air through the open fire doors, are avoided. The steam pressure is constant; the average speed is higher; and the life of the boilers is prolonged.

## What Is an Asphalt Road?

(*Continued from page 151*)

The second course or wearing surface consists of a mixture of hot asphalt, dust, and sand, mixed and rolled in the same way. The sand is finely graded so as to give great strength and stability, while the asphalt binds the whole together closely. The combined thickness of the two courses is usually two and a half or three inches.

Another type of pavement which is more and more widely used both for city streets, boulevards and country roads is the asphaltic concrete or Topeka type. This resembles the sheet asphalt type except that it is generally laid in one course two inches thick, and instead of consisting only of asphalt, dust, and sand, also contains a small proportion of small stone.

The most widely used pavement for country roads is the asphaltic macadam pavement. This is simply a broken stone or macadam road in which the stone is bound together with asphalt. The stone is laid in two courses and the asphalt is poured into it from a machine which distributes it under pressure; the asphalt penetrating the stone and binding it all firmly together. This kind of pavement is often referred to for that reason as a penetration macadam road.

Asphalt is produced from asphaltic petroleum. Petroleums differ very greatly in character according to the field where they are produced. The oils found in the Eastern and Middle Western States are known as paraffine petroleums, while those found in Texas, California, Mexico and South America are known as asphaltic petroleums.

## Electrification in Brazil

(*Continued from page 153*)

is that it gives increased track tonnage capacity by reason of heavier trains, higher speeds and reduction in the number of daily train movements. The other is that the cost of electrification in many cases that have been thoroughly investigated has been found to be considerably less than the cost of corresponding improvements with continued steam-engine operation, and that there is also a return upon the additional capital charge incurred for electrification of from 15 to 20 per cent, resulting from the savings in the operating expense over steam operation.

The eventual electrification plans of the Paulista Railway are for the complete electrification of the line from Jundiahy to Sao Carlos do Pinhal, comprising the greater portion of the main trunk line of the company. This is the second largest railway electrification project in the world, being only surpassed in magnitude by the electrification system on the mountain divisions of the Chicago, Milwaukee & St. Paul Railway in the United States. The St. Paul is electrically operated for a distance of 440 miles. The electrified portion of the road crosses the Rocky Mountains at an elevation of 6,350 feet, the Belt Mountains at an elevation of 5,768 feet and the Bitter Root Mountains at 4,200 feet. The road in these regions presents one of the most difficult problems of transcontinental railroading in the world. Practically all of the important features of that gigantic work will be incorporated in the Paulista electrification.

## Seeing in the Dark

(*Continued from page 154*)

however, the Germans were on the run and trench warfare had practically ceased. The menace of airplane raids, on the other hand, was increasing, and it was decided to develop a similar apparatus for ranging on airplanes. Anti-aircraft guns were rather a joke, insofar as actually hitting anything was concerned. The endeavor was to maintain a heavy barrage and keep the enemy high up so that he could not drop his bombs with accuracy. Sound horns were in use to locate invisible airplanes, and could do so with great accuracy, but unfortunately it took the sound 7 or 8 seconds to get down to the ground from the plane and the shell almost as long to get up there. Usually, by the time the shell arrived at the calculated place the plane was somewhere else. The great advantage of getting the range by heat radiation was that the indication traveled to the ground with the speed of light, almost instantly; in other words, there was no time lag.

Some successful tests were made with model airplanes, and the construction of special thermopiles and a special ranging instrument was at once started. The thermopiles for this work had to cover a much larger field than those for trench use, on account of the great speed of the planes. They were built in a form comparable to the cross hair of an ordinary optical instrument, and are probably the most elaborate thermopiles ever constructed.

This instrument was finished about the time of the armistice, and was tried out in January, 1919, at Langley Field, Virginia. No trouble was experienced in picking up planes a mile away, or in keeping the dark image on the thermopile. By keeping the image constantly on the pile, the speed of the plane could be read directly by the instruments already in use for daylight work. As extended night flying with poor landing fields was extremely dangerous no attempt was made to ascertain the maximum distance at which planes could be picked up. To allow for the low elevation of the plane used in the tests, the motor of a small, low-powered plane was throttled down so that it developed only about 50 hp. It was figured that this small amount of energy would be about equivalent to that coming from one of the large bombing planes at the usual great height. One instrument alone gave only the direction of the plane; two were necessary to give, by triangulation, the height.

The ease with which planes can be detected at night is largely due to this very cold indication of the clear sky. Anything coming in between the sky and the thermopile, either a plane or a cloud, acts as a shutter to cut off the radiation from the surface of the thermopile to outer space, and results in a large warm indication.

The fact that clouds lessened the value of this method of detecting planes at night is not of as much consequence as may appear at first sight. For obvious reasons, raids were very seldom attempted on any but clear nights.

It will be noticed that the original prob-

iem, actual vision at night, had been entirely lost sight of. There was no compensating military advantage to be gained which would have justified the large amount of work entailed in developing such a device. Mere detection in the dark was ample for any military use. As regards the practicability of carrying this work to the point of vision at night, there should be no great difficulty in obtaining a perfect silhouette. It is simply a matter of multiplying the number of units involved. If any commercial use for such a device develops the solution is at hand, but until such a use is suggested it is hardly worth while to undergo the considerable expense of such a development.

## Harvesting the Hay the Latest Way

(*Continued from page 157*)

work much better than the smaller outfit, which requires the same supervision on the part of man. An even more efficient rake for use on large areas is the side-delivery rake, for it enables the hay loader to start taking the hay from the windrow as soon as the side-delivery rake has made one double windrow across the field.

On some farms where considerable hay is raised, it is the custom to bunch the hay by hand, but this is an expensive way compared with the method of bunching with a two-horse sulky rake. Such an outfit can bunch 30 or more acres per day, and a boy can do the work as well as a man.

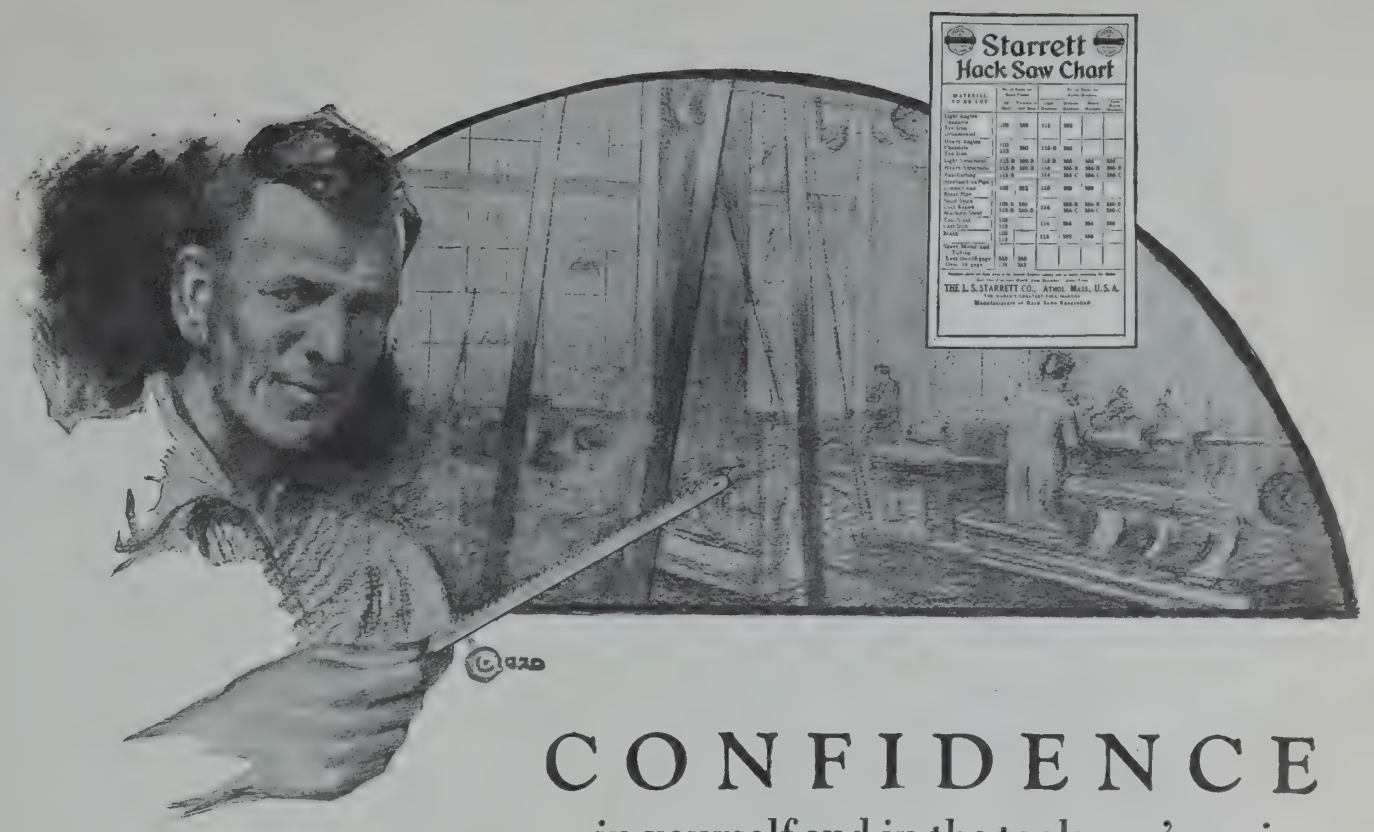
Out in the West, which is a section of "magnificent distances" and everything is done on a big scale, the haymakers have perfected a sweep-rake which reduces by about 50 per cent the labor requirement for harvesting hay, and this method is equally adapted to conditions in the East and South. It is comparatively inexpensive to build and costs little for repairs, and it eliminates a great deal of the irksome hand labor. With the sweep-rake a boy who can drive a team can do the same work as a man.

The sweep-rake consists of several long wooden teeth lying almost flat on the ground, pointed at one end and fastened to a strong framework at the other. The points are sometimes fitted with steel caps over the ends of the teeth and shaped so as to prevent them from running into the ground under ordinary conditions yet so as to slip under the hay, no matter whether lying in piles, windrows or swaths. The teeth usually are about 8 feet long and placed approximately 1 foot apart. The total width of the rake ordinarily is about 12 feet, containing 13 teeth. This gives a surface approximately 8 by 12 feet on which the hay can be loaded and carried.

In operation, the horses or tractor used for supplying power is hitched behind, and the rake is pushed forward gathering up the hay as it goes. The quantity of hay which can be loaded on a sweep depends somewhat on the condition the hay is in, but principally on the skill of the driver and the amount of power available from the horses or tractor. A skilful driver can carry a load of half a ton, and the use of the sweep-rake in large fields will prove very efficient. They are particularly valuable when it is necessary to rake up and stack hay in the field, when a heavy rainstorm threatens.

Another labor-saving device in haymaking that has been perfected in the West is the hay stacker. Where hay is stacked by hand the work is backbreaking and requires strong men, while with the use of the mechanical hay stacker boys can replace men for some of the operations.

Hay stackers are of two general types, according to the way they handle hay. One type has teeth on which it receives hay brought to it by push rakes, and the other handles the hay by means of the harpoon fork, grapple fork, or sling. The first type is represented chiefly by the



CONFIDENCE

—in yourself and in the tools you're using means efficient work.

Mechanics who use Starrett Hack Saws according to the Starrett Hack Saw Chart, are sure of their results. Starrett Saws are sold upon the *confidence* mechanics have in them.

A saw for each kind of material to be cut—each blade made of the finest grade of hack saw steel. And behind them the Starrett Service, helping hack saw users to get every bit of value out of Starrett Blades that we put into them. That's why they "cut quicker and last longer."

Begin to-day to lower your cost per cut. Write for "Hack Saws and Their Use," the first practical book on hack saws ever published.

"The book that helps you lower your cost per cut."

ATHOL, MASS.

42-83

Use Starrett Hack Saws

## The Essentials of Hack Saw Efficiency

*(From "HACK SAWS and their use." L. S. Starrett Company)*

Knowledge, training, and experience are as necessary to the efficient use of Hack Saws as of other cutting tools. Failure to appreciate and profit by this fact leads to unnecessary waste of saws, material, time and labor—to an amount far larger than is generally realized. Because of the universal use of the Hack Saw, both as a hand and a power driven tool, and because of the great variety and the lack of uniformity in the work it is called upon to do, regulation and control in its use have been somewhat difficult.

Taylor and other exponents of scientific management have taught us much regarding the efficiency of cutting tools and we have profited by it; but until Hack Saw practice was standardized by the establishment of the Starrett Hack Saw Chart, there was no definite basis for economic progress in this field.

### The Essentials of an Efficient Saw

In selecting a Hack Saw, three objects should be kept in mind:

*a*—The blade must cut fast.

*b*—The blade must do the maximum amount of work at the minimum combined cost of the saw itself and the labor and overhead chargeable to the operation.

*c*—The blade must be suited for use on the largest variety of materials possible without interfering with "a" and "b."

### A Practical System of Blade Selection

Any system of blade selection to be really practical must be based wholly on the material to be cut, rather than on any classification of blades according to a list of trades or an arbitrary classification by number. Were it possible to say that in any particular trade only certain classes of material were cut, such a classification would be ideal; but dividing the metals according to their influences on cutting speed, saw life, etc., which is the only true basis to use, it is practically impossible to say that any given trade will have occasion to cut only a definite portion of the list. Efficiency is best served by classifying the various materials, the one group of factors with which every operator, skilled or unskilled, is familiar, and putting opposite the name of each metal the catalog number or designating letter of the saw which should be used. A copy of the Starrett chart will be sent free upon request.

# In "the good old days"—when meat was "cheap"

Years ago people were buying steaks and chops "cheap" and other meats in proportion.

It is true that meat prices are higher today—and so is the price of live stock.

But—

If present-day methods had been in use fifty years ago, meat would have cost our fathers and mothers and uncles and aunts even less than it did!

Many parts of the animal were actually thrown away; the business was done in small unsanitary plants.

As a matter of fact, meat was *not* cheap in the early days as compared with the price of live stock. See what U. S. Census figures show:

In 1870 it took nearly 19 per cent of the value of meat products to cover the packer's expenses and profits for turning animals into meat; the latest census shows that with modern methods it took less than 13 per cent of the value of meat products to perform this same service.

This smaller relative "spread" between live stock and meat prices is due to development of large scale operations and elimination of waste. It means that meats are cheaper today than they used to be, compared with the cost of raising live stock.

Out of all receipts from the sale of animal products last year, Swift & Company paid out over 85 per cent for the live animals. The other 15 per cent covered all plant, shipping, and selling expenses—and also the profit, which averaged only a fraction of a cent per pound on all products sold.

*Now Ready! A New Book on a New Subject*
**BEHIND THE MOTION-PICTURE SCREEN**
*By Austin C. Lescarboura*

HERE, at last, is the wonder book of the screen. It takes the reader into that marvelous land where films are made, and where the camera reigns supreme. Every step in the making of a photo-play is taken up in proper turn, from the planning and writing of the scenario to the projecting of the finished film on the screen in the picture.
Talking pictures, natural-color pictures, microscopic pictures and all phases of the motion picture are treated upon in due turn. This book is printed on the highest grade coated paper. It contains 428 pages and over 300 illustrations. Bound in an attractive cloth cover. Send for four page circular giving sample page and full table of contents.
*Size 6¼ x 9½, $3.50; postage—15c in the East, 20c to Chicago, 30c to the coast*
***One of the Most Attractive Books Ever Issued***
SCIENTIFIC AMERICAN PUBLISHING COMPANY 233 BROADWAY, NEW YORK

"overshot" and the "swing-around" stacker. Each of these has long wooden teeth, like those of a push rake. The push rake drops its load of hay directly on these teeth. When the push rake is operated properly, there is no necessity for hand work, except that occasionally it may be necessary to gather up scattered hay with a fork when several push rakes are used. Two horses, or a tractor, are used to elevate the hay to the proper height to be dropped on the stack.

The second type, stackers that do not receive hay directly from push rakes, but handle it by means of horse forks or slings, are usually home-made stacking outfits, and there are a number of these. The cable stacker is one of the simplest and most generally used, and consists of an A-shaped frame higher than the hay stack to be built, to which is fastened a steel cable on which the carrier travels. The materials for such a stacker can be obtained on the farm or from any hardware store. The single-pole or derrick stacker is used to a considerable extent, and it consists of a single pole long enough to make a stack of the desired height, to which is fastened a shorter pole, or boom, at right angles. Three pulleys, about 100 feet of rope, and a horse fork complete the outfit. Where a number of stacks are to be built, it is customary to mount the pole on wheels or on runners, which can be easily moved. The pole is supported by three or four guy ropes or wires.

In what is known as the "Black Belt" in Georgia, Alabama and Mississippi, there has been developed a successful type of truck for curing hay. In this section the principal kinds of hay grown for market are alfalfa, Johnson grass, and alfalfa and Johnson grass mixed. The hay-making season covers a period of several months, and from three to five cuttings are obtained per year. The great drawback in producing hay, however, is the difficulty in curing the hay during unfavorable weather. The hay-curing truck was designed to enable the grower to cure hay during rainy or cloudy spells of weather when all ordinary methods of curing in the field failed.

The curing truck is a device which supports hay during the curing process, protecting it from rain and from moisture in the ground. It requires no more man labor or horse labor for loading, unloading or hauling than do the more familiar methods of curing.

The truck is quite similar to the ordinary hayrake. It is 12 feet long and 7 feet wide and will hold from 1,500 to 2,000 pounds of cured hay, depending on how much the hay is cured when put on the truck. The back is supported by two 16 to 20-inch steel or iron wheels running on an axle placed about 4 feet from the rear end of an A-shaped frame. When a loaded truck is not in motion, as when left in the field for the hay to cure or while it is waiting to be baled, the front end is supported by a 6 by 8-inch wooden block or "trigger" of sufficient length to hold the truck level. This trigger is fastened between the two main frame timbers by a heavy bolt, enough play being left so that it swings easily by its own weight. When the trigger is not in use the free end, pointing to the rear, drags lightly on the ground. The trucks are moved by means of a two-horse team and by reason of their being moved from place to place, the hay can be either left out in the open on bright days or placed under shelter in times of storm. A canvas covering will protect the hay from the top, and the hay being off the ground, will prevent being spoiled by excessive ground moisture.

## The Racing Airplane of the Future

(*Continued from page 158*)

will be built also of thin sheet metal, and will be generally elliptical in cross section; two very light trusses, one horizontal, the other vertical, extending from the operator to near the tail. The chords of these trusses will be formed of light T-iron.

To provide for the heavy loads and stresses that are concentrated at the wings and motor, the T-irons of the trusses will be increased in depth and run entirely around the forward end of the body, forming, at their intersection in the nose, a strong construction for carrying the motor. Additional strength will be provided by transverse diaphragms. It is understood, of course, that all of this metal work will be specially rolled in extremely light sections, and that the material will be some alloy, such as vanadium steel, which in experimental specimens, as noted on our editorial page, has shown elastic limits running up to over 200,000 pounds to the square inch. The motor of from 75 to 150 horse-power, according to the size of the airplane, will probably be of the revolving type; the Gnome motor having shown itself to be the ideal airplane drive.

Turning to nature for guidance again, we find that the fast-flying birds fold their legs snugly beneath them when in flight. The racing airplane must do the same. We show a suggested arrangement for a folding chassis, hinged just below the body, and provided with a yoke which leads from the axle up to the crosshead of a piston rod, which, with the guides and cylinder, is carried by the T-iron that forms the bottom member of the vertical truss. The cylinder is provided with a two-way valve and connections by which compressed air can be introduced to the forward or after end of the cylinder. When the chassis is down and in operation, the compressed air acts as a cushion to provide a certain amount of fore and aft movement to the wheels. As soon as the machine rises, a throw of the valve introduces compressed air at the forward end of the cylinder, and the chassis is drawn up snugly against the body. A small tank of compressed air, which supplies the folding mechanism, also supplies a small cylinder of similar construction placed transversely to the car, which operates the movable wing tips. The two-way valve of this cylinder is controlled by a small gyroscope, which may be thrown out of gear when the airman wishes to make a turn, or perform other evolutions.

In answer to the question as to what speed may be expected from a machine of this general design, we think it will be agreed that, in view of its sweetness of form, the complete absence of wires, struts and other energy-consuming surfaces, and the fact that because of the smoothness of the steel surface, skin friction will be reduced to a minimum—it is conservative to expect from such a machine, after it has been developed by experimental work, speeds of from 100 to 125 miles an hour.

It would be interesting to see what Mr. Herreshoff could accomplish, if he applied to the steel airplane the same constructive genius which enabled him to produce such fine results with steel racing yachts.

## Helmets and Body Armor in Modern Warfare

(*Continued from page 159*)

seded the "porridge bowl" English helmet. It was made of manganese steel, and it has the advantage over the old type that it protects the back and sides of the head better than the earlier model.

We show also an American experimental back plate which is laminated. It is made up of a large upper plate, two intermediate pieces, and a lower-most plate, or *garde reins*. These elements are riveted together and are made interflexible by the use of slotted grooves in which the rivets can travel, as in the old-fashioned "alemayne rivets." The back plate is made to suit wearers of many sizes, and it is cushioned with sponge rubber that serves to protect the wearer against injuries from indentation of the metal. It will stop a bullet traveling at 1,000 feet per second.

# FIVE OIL MISTAKES

## *How to stop maintenance dollars from blowing through the exhaust*

MOTORISTS are looking for scientific ways to reduce upkeep. Old mistakes—always costly—today positively extravagant—must go.

Here are five common lubrication errors. They are responsible for many of the operating troubles that motorists experience.

### MISTAKE No. 1

***"Oil is a good thing —you can't have too much of it."***

Some motorists believe that if the oil reservoir is filled above the indicated high level, better lubrication will be provided. They are mistaken. Oil should be kept at the proper level —no higher. Over-filling causes excessive carbon, gummed valve stems and sooty spark-plugs.

### MISTAKE No. 2

***"I use heavier oil because my engine's badly worn."***

Many motorists believe that a change to heavier oil is advisable in a worn engine. This is not so. Worn engines need *overhauling*. Heavier oil is no substitute for worn parts. The lubrication system of a car may be wholly unsuited to properly distribute a heavier oil than specified in our Chart of Recommendations.

### MISTAKE No. 3

***"Old oil never does any harm in the crank-case."***

Some motorists neglect to drain the old oil from the crank-cases of their engines at frequent intervals. The correct oil is not destroyed in use. But it does become contaminated with grit drawn in through the breather, with carbon particles from the undersides of the pistons and with water from condensation. It also becomes thinned out with fuel absorbed by the oil film on the cylinder walls, especially when the mixture is too rich. For these reasons old oil should be drained from the crank-case frequently.

### MISTAKE No. 4

***"When refilling I always clean out my engine crank-case with kerosene.***

This procedure sounds logical—hence has come into common use. Experience shows, however, that it is almost always a mistake, for some of the kerosene is usually retained in the splash troughs or other oil pockets in most crank-cases and thus thins out the new oil. The better plan is to drain the crank-case when the engine is hot. This will carry off the sediment before it settles. Then flush out with a quart of fresh oil and refill to the correct level.

### MISTAKE No. 5

***"My oil seems to work all right."***

This, perhaps, is the grandfather of all lubrication mistakes. "My oil seems to work all right" sends more cars to the repair shop than all other causes combined.

The motorist cannot watch from day to day the inside of his engine Hence he is in no position to know accurately the effects of different oils. While many oils may "seem to work all right," only *one* of those oils may be giving him scientific lubrication. And only that *one* can give him —the lowest fuel bills, the lowest oil bills and the lowest repair bills.

The Chart at the right specifies the grade of Gargoyle Mobiloils which is scientifically correct for *your* car.

The use of that oil and the avoidance of the common mistakes mentioned here will show you *engine results*—economy and power—which you may never have had before.

## Chart of Recommendations *for* AUTOMOBILES

(Abbreviated Edition)

GARGOYLE

# Mobiloils

*A grade for each type of motor*

### How to Read the Chart

THE Correct Grades of Gargoyle Mobiloils for engine lubrication are specified in the Chart below

A means Gargoyle Mobiloil "A"
B means Gargoyle Mobiloil "B"
E means Gargoyle Mobiloil "E"
Arc means Gargoyle Mobiloil Arctic

**These recommendations cover all models of both passenger and commercial vehicles unless otherwise specified.**

Where different grades of Gargoyle Mobiloils are recommended for summer and winter use, the winter recommendation should be followed during the entire period when freezing temperatures may be experienced.

This Chart is compiled by the Vacuum Oil Company's Board of Automotive Engineers, and constitutes a scientific guide to Correct Automobile Lubrication.

If your car is not listed in this partial chart, consult the Chart of Recommendations at your dealer's, or send for booklet, "Correct Lubrication," which lists the Correct Grades for *all* cars.

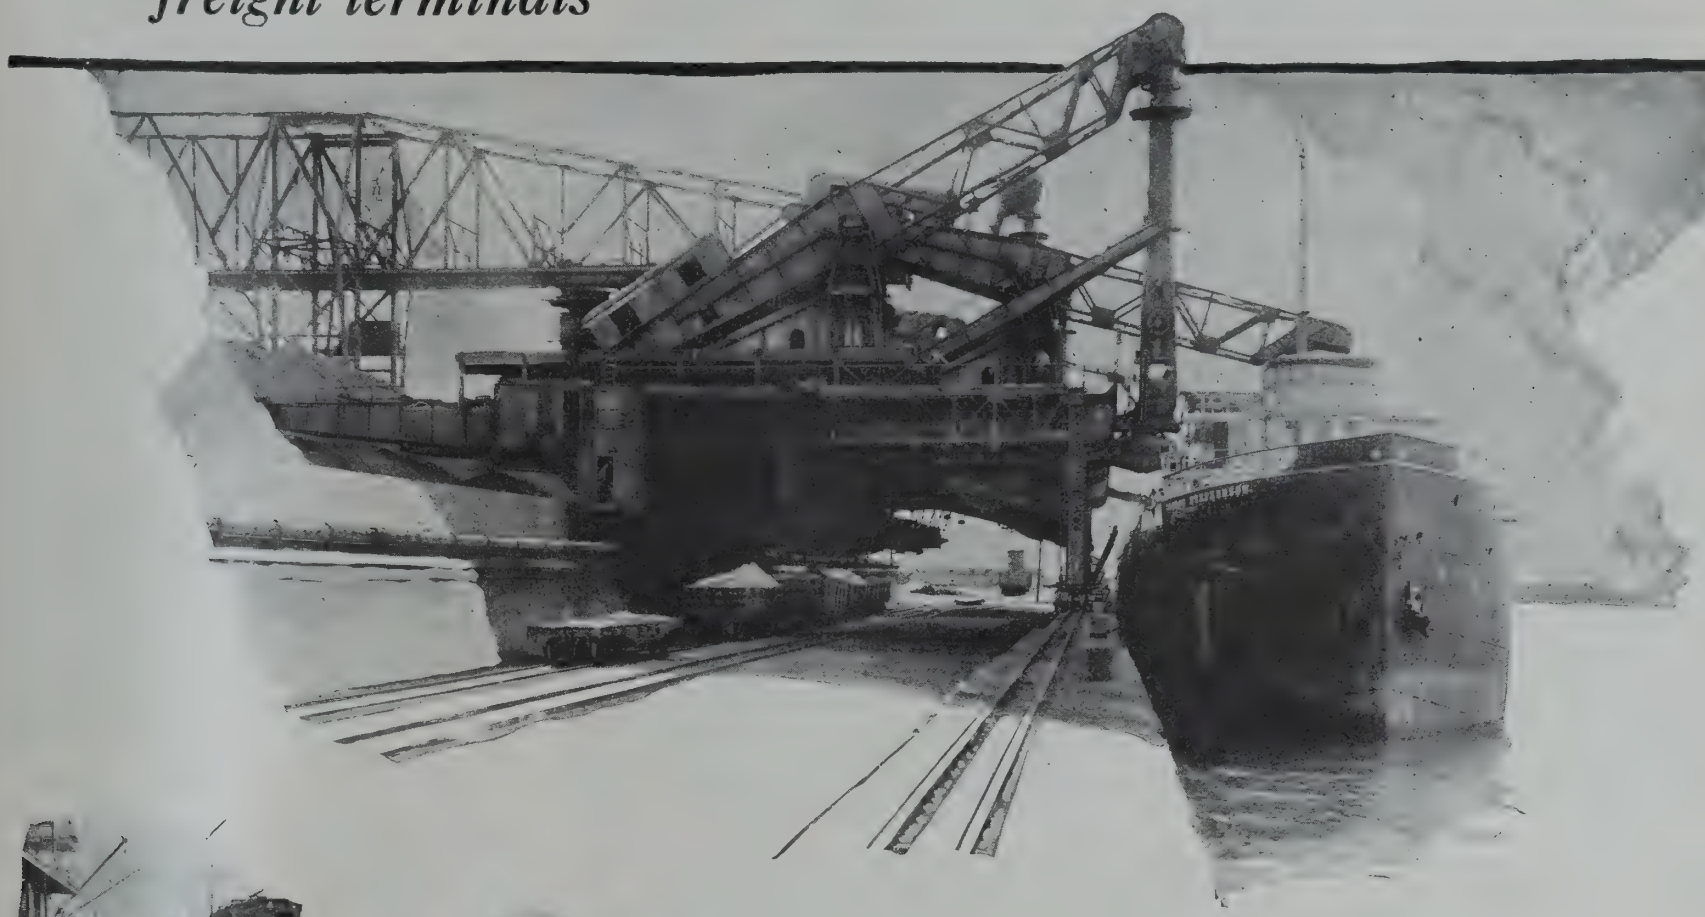
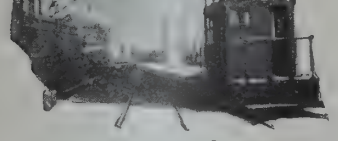
# VACUUM OIL COMPANY

*Specialists in the manufacture of high-grade lubricants for every class of machinery Obtainable everywhere in the world*

# NEW YORK, U.S.A.

*The immediate solution of material handling problems is essential to the efficient development of marine and inland freight terminals*

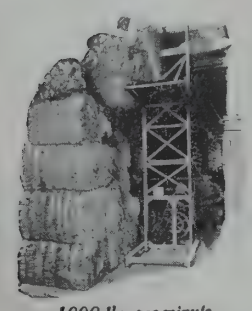




*Trolley Type Surface Locomotive works fast between ship and warehouse*

*Portable Elevator handling a ton a minute*

*Tractor and Trailers speed production*



*1000 lbs. per minute lifted from 30 to 50 feet in height*

*Storage Battery Locomotive hauling 50 tons of copper plates*

## *How electricity improves terminal facilities*

THE science of building great ships is not without a parallel science of building equipment to load and unload them. Today, when a big ship docks, a giant power quickly gets under way to clear the hold—this power is electricity applied to large and small material handling devices.

Unloading ore at the rate of fifteen tons per minute is the way the Hulett unloader works for one dock company. For loading and unloading cargoes at ports, the electric crane and hoist prove to be the most economical, most flexible, and most rapid of all machinery. For short distance moving of material, the electric conveyor speeds the work.

Where goods have to be moved greater distances along piers or in warehouses, the storage battery tractor and trailers make quick headway—and portable elevators stack high, neat piles in fast time. In the yards of big industries, electric locomotives simplify transportation problems.

All these devices, electrically equipped and controlled, are busy and consistent factors in conserving hours, and eliminating congestion in handling the world's goods.

Your needs of material handling equipment can best be filled by the manufacturer who, in building his product, obtains the specialized electrical experience and products of the General Electric Company.

# Putting horse-power over the jumps

THE blasting heat that most of us have felt as a boiler fire door is opened is cool compared to the white hot gases further in, that rise from the incandescent fire bed to be sucked back through the boiler and to the stack.

Their rush is swift, but before they can reach the stack, they have been forced to take the longest and most devious path through great racks of water-filled tubes, so that the water in the tubes will have every possible opportunity to absorb the heat from the gases.

To force them to take this longest path through the boiler, hurdles have been devised by engineers, over which this plunging flood of heat, energy, horse-power, must go, over and under, and up and down.

These hurdles, or baffle walls, as they are called, once presented many difficulties from a structural standpoint. They obviously must withstand great heat. They must be flame-tight, even though necessarily pierced and honeycombed by hundreds of tubes that change size as they heat or cool.

Johns-Manville has introduced a new departure in baffle construction, that of pouring the wall around the tubes just as concrete is poured.

Such baffle walls are really leak-proof and resistant to high furnace temperatures, and unaffected by contraction and expansion of the tubes passing through them. They make new fuel economies possible in steam boiler operation.

This is but one of the many departments of Johns-Manville Engineering in the great cause of power saving. In addition to Baffle Walls, a complete line of *High Temperature Cements* has been developed to protect boiler fireboxes, retorts, cupolas, and dryers, from destruction by high heats.

For the prevention of air leakage or infiltration there are other materials to be applied to the outside of boiler settings—all a most vital work in the conservation of fuel.

**Here are a few Johns-Manville products:**

*Monolithic Baffle Walls*
*Refractory Cements*
*Asbestos Insulating Cements*
*Asbesto-Sponge Felted Pipe Insulation*
*Asbesto-Sponge Felted Sheet and Block Insulation*

## Emptying Eight Freight Cars into a Thimble

PICTURESQUE Long Park Plateau, in the Paradox Valley, Colorado, is the location of the group of radium luminous material claims which are steadily producing tons of radium-bearing carnotite. The nearest railroad is 58 miles distant, a trip of three and a half days for the six-horse wagons over rugged country, too rough for even light motor trucks.

Starting east with 250 tons of carnotite, a few weeks' production at the Long Park mines, filling 8 freight cars, the ore travels 2,600 miles through Denver, Chicago and New York, until the cars are finally unloaded at the main radium luminous material plants in Orange, New Jersey.

Scientific knowledge and infinite patience reduce that tremendous bulk of 250 tons of ore to scarcely a *thimbleful* of radium, Three distinct plants and hundreds of processes make possible the final desired reduction—*one gram* of radium element.

It seems inconceivable that a gram, which is approximately *1/28* of an ounce, can be worth $120,000. Yet this is true of radium and when one realizes that that tiny amount of radium combined with 20,000 grams of the secret process phosphorescent zinc sulfide results in sufficient radium luminous material to self-light for life *667,000* watches or clocks, the true value of radium to modern society is apparent.

In other words, one gram of radium plus 20,000 grams of zinc sulfide equals enough radium luminous material to self-light the time piece of every male adult in the City of New York.

All of which is interesting in view of the fact that the State of New York has recently purchased two and a quarter grams of radium, the largest commercial transaction of its kind ever made and the first purchase of radium by any State for a purpose of social utility. The 1920 State Legislature voted an appropriation of $225,000 for the purchase of the radium. The reason why this rather imposing sum does not go very far in the purchase of radium is as stated above; but perhaps it will be a little more clear if we consider the direct visual appeal of the drawings herewith.

The radium is to be used for research work in behalf of the New York State Institute for Malignant Disease, under the direction of Dr. H. R. Gaylord and his staff in Buffalo. The first shipment of one gram—about one-thirtieth part of an ounce, was delivered to a representative of the Institute in a lead cylinder eight inches in diameter and a foot long. The Bureau of Standards tested the radium and certified as to its weight and purity.

**These graphic comparisons tell why a gram of radium sells for $120,000**

## No Relation Between Cultivation and Rainfall

CAREFUL scientific records kept by the National Weather Bureau for more than a half century show irrefutably that the time-honored theory that the cultivation of semi-arid land increases the amount of rainfall in that region is wholly incorrect. During the period under discussion a decided increase in the area of cultivated land is noteworthy in the Great Plains States and yet there has been no definite and permanent increase in the precipitation records of that section of the country. The rainfall reports of Uncle Sam's scientists show that during the period from 1868 to 1892 inclusive the average precipitation for the Great Plains States was 19.25 inches while for the period from 1893 to 1919 the average rainfall was only 18.58 inches despite that the acreage of tilled crops increased very appreciably during the latter interval.

Furthermore it has been conclusively demonstrated the wet years and dry years do not occur—as popularly believed—in periods of two to three years each. There is no regular or routine occurrence of these times of drought or abundant precipitation. Sometimes the dry years come during wet periods or vice versa. It is not possible to predict potential precipitation from past records. A wet year may be followed by a very wet one or a dry year may succeed another dry one as the case may be. However, years of abundant and well distributed rainfall encourage a western extension of the cultivated area, and when a succession of favorable seasons occurs the farming operations are pushed much farther west into regions which ordinarily do not provide anywhere near enough moisture for profitable crop production. The following season may be a dry one and the boundary line for cropping activities may again be carried far eastward of its previous location. The rainfall of the Great Plains section varies considerably from one season to another but its vagaries are, in no respect, due to the increase or diminution in the area of tilled crops planted and harvested.

## Protection of Steel from Rusting by Painting

SOME useful notes on the protection of steel structural work from rust by means of painting are given by J. H. Shean in the *Canadian Engineer*. According to the author, the first coat of paint laid on the well-cleaned steel-work is of great importance from the point of view of rust prevention. The most generally accepted "inhibitive" pigment is red lead. It is now possible to buy red lead containing only 2 per cent of litharge (which in excess causes the troubles associated with this pigment) and 98 per cent true lead, PbO. This makes an ideal paint for a first coat. Being extremely fine it fills all pores and brushes out in a smooth, even film, free from voids. It stays in place on vertical surfaces, and does not act ropy under the brush. The vehicle with which the lead is mixed is fully as important as the pigment itself. The merit of linseed oil is well known, although the paint film is much better if reinforced with Japan oil. Japan oil, besides reinforcing the oil film against shrinkage, furnishes sufficient driers of the right kind. The amount of red lead to be used in one gallon of vehicle is a question on which engineers differ, the general average for railroad use being about 25 pounds to the gallon.

The usual dark aftercoats are probably all good if applied rightly, but the fact remains that they are all heat attractors. Unless the price of material is the main consideration, there is no reason why steelwork should not be painted in light colors and their resistance to heat rays would certainly be easier on the oil film which holds the pigment together than the dark colors which attract and hold the heat rays. The light colors will last sufficiently longer than dark colors to pay any extra expense. It may be argued that light colors become unsightly in a short time from dirt and smoke. This cannot be noticed to any extent except overhead on through truss bridges and overhead bridges on which even if painted black smoke marks show.

It would appear from this rather detailed discussion of the scientific aspects of what has usually been looked upon as a commonplace to be settled by the rule of thumb or the buyer's whim, that it will indeed be a paying proposition to subject the painter's materials and technique to thorough scrutiny.

## Modernizing the North River Waterfront

THE agitation in favor of a thorough reconstruction of the facilities of the Port of New York has shown its first fruits in the plans of the Department of Docks for a complete rebuilding of thirty-two piers extending north from Vesey Street on the Manhattan waterfront of the Hudson River. Credit for this extensive work is due to Dock Commissioner Murray Hulbert, who is now abroad for the purpose of studying the up-to-date facilities of the leading ports of Great Britain and the Continent. Briefly stated, the plan contemplates the removal of thirty-two of the present narrow piers, with their inadequate slips and the construction, in their place, of eighteen modern piers, with wide slips between them, capable of accommodating the largest vessels.

Every one who is familiar with conditions at this port has known that our pier system was antiquated; and that portion of the recent report of the Dock Commissioner which deals with the history of this stretch of the Hudson River pier system reveals how antiquated it is, and gives some very interesting data as to its inception and subsequent development.

We are told that up to the year 1830 the shore along the North River consisted of a series of beaches, with occasional landing platforms built out over them. The commerce of the city was carried in sailing vessels, which were moored in deep water, the freight being transferred between ship and landing stage by small boats. Then the citizens who owned waterfront grants where the water was sufficiently deep, began bulkheading their properties so that vessels could lie alongside and discharge and load direct to shore; and it was this work that marked the beginnings of what is now known as West Street. The next development came in 1857, when the Board of Aldermen began to bulkhead the shore and build piers; and thereafter no private owner was permitted to build piers without permission of the city authorities.

Shortly after the Civil War, the need for a comprehensive plan was felt, and in 1870 the first Board of Docks was created, and Gen. George B. McClellan, as its chief engineer, drew up the plan of 1871, which provided, between Vesey and Perry Streets, a continuous bulkhead line, with a pierhead line 600 feet out in the river. Piers not over 600 feet in length were located at definite locations. The traffic requirements of that day and the future were believed to be amply met by making these piers from 40 to 60 feet wide, with slips between them of from 100 to 150 feet. Many of those piers are in existence today.

Now McClellan was a capable engineer and we may be sure that both he and the civic bodies in consultation with which he worked believed that in this, the first comprehensive layout of the Manhattan waterfront, they were making ample provision for future developments, both as to the size of ships and the magnitude of the traffic to be handled.

It would be unjust to the city fathers of that day to say that they were lacking in vision; rather, the present congestion is to be blamed upon the city administrations of a later day for failing twenty-five years ago to at least commence the reconstruction which is now to be undertaken after a lapse of fifty years.

The moral of the whole thing is obvious. When Commissioner Hulbert returns he should subject even the present plan to mature consideration, based upon the data he has gathered in Europe where piers of from 300 to 500 feet width are common. Furthermore, any plan for improving the North River waterfront should be worked out with a view to its coöperation with the double-deck elevated railway, which will ultimately be built from the North River Bridge at Fifty-ninth Street to the Battery.

We are gratified to note that the plans for the new piers provide for a 30-foot apron at the side of the piers for railway tracks which will be spanned by gantry cranes. This is in line with the latest practice, and it will add immensely to the rapidity of turn-around of the ships that lie at these piers.

## Double-Decking a Cure for Street Congestion

PROBABLY there was never a time in the history of this city when the matter of congestion of our city streets and the remedies therefor received so much attention as it does today. The files of the SCIENTIFIC AMERICAN show that many decades ago plans were being suggested for getting rid of the congestion which even then was felt to be intolerable. But conditions that were intolerable then would today be welcomed as a positive relief in some of our more crowded centers on Fifth Avenue and downtown.

Of all the suggested plans for relief, none would be so immediately effective as the double-decking of a few of our most congested arteries of travel. We have always strongly advocated this plan, in favor of which everything can be said and against which there is no serious objection. The double-decking of a street would immediately double and more than double its capacity, since it would not only double the number of foot passengers and vehicles that could comfortably make use of it, but, because of the greater fluidity of this traffic there would be a resulting increase in the number of people and vehicles that could pass a given point in any period of time on each level.

The city of Chicago is satisfied that double-decking is practical, and it is going to carry out a work of this character in what is known as the South Water Street improvement, which will extend for several blocks, or about 3,500 feet, along South Water Street. Several purposes are to be served, the first of which is to secure a new east and west thoroughfare on the margin of the well known "loop," the central business district of Chicago, which will serve as a by-path for heavy traffic which now crosses the route. Also, it will avoid interference of east and west trucking traffic with normal north and south traffic over the river bridges. Fronting on the river it will naturally provide freight handling facilities; and also, in addition to separating the fast and slow traffic and increasing traffic capacity, there are certain auxiliary advantages secured in the way of providing parking accommodations for automobiles, and the facilitating of the delivery of freight to adjacent buildings on two levels.

All heavy motor trucks, trolley and horse-drawn vehicles would be confined to the lower level, the upper deck being reserved for light motor trucks and automobiles. The absence of tracks would make it possible to utilize the center of the upper roadway for the parking of automobiles—an arrangement which would greatly increase the number of people who use their machines to reach their business offices. The upper deck would extend down the crosstown streets at the more congested centers; elsewhere, access would be had by means of inclines. These would be less than half the width of the side streets; the ramps for downtown traffic leading west and those for uptown traffic to the east.

Now all of these advantages, with the exception of those pertaining to river frontage, would be secured if the same method of double-decking were applied at some of our most congested centers, say on Broadway, Fifth Avenue and certain of the crosstown streets. By judicious coöperation of the engineer and the architect, the upper deck could be so laid out as to avoid the unsightly constructions which form our elevated railroads. An obvious suggestion looking to this end would be to build the supporting columns and floor beams in a series of flat arches and encase the whole in white glazed terra cotta. For lighting the lower deck or street level, it would be sufficient to reserve the upper deck for light automobile traffic and fill in the floor from curb to curb with a heavy design of skylight construction, similar to that now used on passenger sidewalks. Heavy trucking would be relegated to the lower deck at street level. An incidental advantage of this system would be that the store frontage along the street would at once be doubled, since property owners would readily appreciate the advantage of having additional window display on the second floor. Another and very practical advantage would be that the lower deck would afford a completely sheltered thoroughfare in rainy weather and during the snows and frosts in the winter time.

## Our Share of the Surrendered German Ships

IT was difficult to realize that the five rusty and unkempt ships, the battleship "Ostfriesland," the fast cruiser "Frankfurt," and three destroyers, as they made their way slowly into New York harbor, were once among the finest representatives of their respective types in the German navy. In their war-and-weather-worn condition could be read the tragic history of the German navy since the battle of Jutland; for to the scars of that battle have been added the neglect of several years of inactivity in German ports. and the marks of long submersion beneath the waters and in the mud of Scapa Flow.

The question has been frequently asked as to what disposition will now be made of these ships. So far as the inclusion of any of them in our Navy is concerned, it may be stated at once that, though they came into harbor flying our flag, none of them will ever go into active commission—this for the reason that the terms of their award to the United States by the Allied Naval Commission, after they had been surrendered under the Versailles Treaty, provide that they must be destroyed within one year.

The tentative plans of the Navy Department contemplate the exhibition of the battleship "Ostfriesland" in a few of the leading ports of the country, after which, in accordance with our engagement, the five vessels will be destroyed. Previous to that, however, a thorough study of their hull construction and armor plan and of their engines will be made by representatives of the Bureaus of Construction, Engineering and Ordnance. After that the "Ostfriesland," at least, will be allocated to a service in which she will prove to be of the greatest value to the Navy. She will be used for target practice and gradually shot to pieces for the sake of the invaluable lessons which can thus be learned. It will be remembered that one of our early battleships, the "Texas," renamed the "San Marcos," was used for the same purpose.

What renders the "Ostfriesland" of such great value as a target is the fact that the Germans paid particular attention to the protective elements in their battleships, and that they probably put a larger percentage of the displacement of their ships into deck and side armor than any other contemporary navy. Their armed vessels received a terrific hammering from the 13.5- and 15-inch guns of the British, and it was their very excellent armor protection, and particularly the protection afforded to the vitals by well-disposed deck armor, which kept the high-explosive shells out of the magazines and enabled the badly punished fleet to get back to port.

Not only will the "Ostfriesland" give us an excellent opportunity to determine just how much and what kind of damage the various types of shell can do on a comparatively modern battleship, but she can be used for practice at those extreme ranges of 18,000 to 20,000 yards and over at which future engagements will probably be fought.

As to the fast cruiser "Frankfurt" and the three destroyers, it is certain that even if the terms under which we received these ships did not call for their destruction within a year, they are in such poor condition as the result of neglect and submersion at Scapa Flow that it would never pay to repair them for use in our own Navy. Even if they could be refitted and placed in commission, they are so different in speed, accommodation, character of armament and general maneuverability that it would be difficult, if not impossible, to fit them conveniently into our fleets.

## Naval and Military

**National Guardsmen to Enter West Point.**—The attention of the Governors of the several states has been called by the War Department to the fact that enlisted men of the National Guard who on July 1st, 1921, shall be from nineteen to twenty-two years of age and shall have served one year in the National Guard will be eligible for selection as applicants for admission to the National Military Academy.

**The Fastest American Destroyers.**—All American records for speed were broken by the torpedo boat destroyer "Satterlee" during her standardization firing over the measured mile off Rockland, Maine, when she made a mile at the rate of 38.26 knots. The best previous record of 37.04 knots was held by the American destroyers "Dent" and Wickes." The boat also established a new record in her class for horsepower, developing a maximum of 31,223. The "Satterlee," which has been in commission six months, was built by the Newport News Shipbuilding and Dry Dock Company.

**The Fifteen-Inch Guns on the "Hood."**—At first sight it may seem strange that the "Hood" should carry only the same armament as the "Queen Elizabeth," built some eight years before the "Hood." As a matter of fact, the "Queen Elizabeth's" guns are forty-two calibers in length; but the guns of the "Hood" are forty-five calibers long and have greatly increased muzzle velocity. It is believed that the gun weighs a little under one hundred tons and fires a 1,950-pound shell with a muzzle velocity of 2,800 foot-seconds. Another improvement over the "Queen Elizabeth" is that the new guns have an elevation of thirty degrees for a maximum range of 38,000 yards. The loading gear has been so improved that the "Hood" is credited with being able to fire a salvo of eight guns every thirty-five seconds.

**The Aircraft-Carrier "Eagle."**—When the British decided to build a fleet of aircraft carriers they changed the design of one of the battleships so as to provide landing and starting platforms and interior accommodations for aircraft. This ship has recently been completed, and she forms the third large aircraft carrier, the others being the well known "Argus" and "Furious." Many British officers consider that the "Eagle" is altogether too slow to make an efficient aircraft carrier. She was originally constructed as a dreadnought battleship for Chili. Her designed speed was 22.75 knots, and it is possible that her lightening up due to the removal of heavy guns, ammunition, et cetera, may have enabled the speed to be raised to 25 knots. An aircraft carrier, however, should have at least 30 knots speed.

**Japanese Strength in Super-Dreadnoughts.**—We are not among those who believe that the growth of the Japanese fleet represents any threat to our naval supremacy in the Pacific. When the super-dreadnoughts that Japan has built or now has on the ways, or has proposed for construction, have been completed, she will have in dreadnoughts of the first class only a little over one-half the super-dreadnought strength of the American fleet when the three-year program of 1916 has been built. At present she has four of this class and has under construction four others, so that when all are completed she will have a total super-dreadnought tonnage of 251,000. Even if our super-dreadnought fleet is equally divided between the Atlantic and the Pacific, we would still have a great excess in strength in the Pacific over this Japanese fleet.

**Warship Tonnage of the World.**—In a statement made by Rear Admiral Albert P. Niblack, Director of Naval Intelligence, before a Committee of Naval Affairs, the warship tonnage of the principal naval powers on July 1st, 1919, was as follows: The vessels completed in total tons were, for Great Britain, 2,652,130; the United States, 1,160,355 tons; France, 623,850 tons; Japan, 580,716 tons, and Italy, 454,293 tons. The total tonnage of ships building was for Great Britain, 246,650 tons; for the United States, 995,313 tons; for France, 247,050 tons; for Japan, 267,250 tons, and for Italy, 147,250 tons. These figures for ships built must be reduced for Great Britain by several hundred thousand tons, for the 150 vessels, including pre-dreadnoughts which have been stricken from the list. Similar deductions on a smaller scale should be made for the other powers.

## Astronomy

**More Newspaper Astronomy.**—An English newspaper, quoted in *Popular Astronomy*, undertakes to answer the question "Why Is the Moon Not Always Round?" and enlightens its readers in the following terms: "It is. The reason it changes in appearance is that the earth's shadow is thrown upon it by the sun, and the size of the shadow varies each night when the moon is visible."

**Sunspots Visible to the Naked Eye.**—The frequency of sunspots large enough to be visible to the naked eye is greater than is generally supposed. At a recent meeting of the British Astronomical Association it was stated that members of the Solar Section of the society had observed the sun with the naked eye on 302 days during 1919, and on 126 of these days spots had been seen with the naked eye.

**Spectroscopic Parallaxes.**—Messrs. Adams, Joy and Strömberg report that the rapid accumulation of parallaxes determined with a high degree of accuracy by the trigonometric method has made it possible to complete a revision of the standards of reduction used in the new spectroscopic methods of determining parallaxes, and to derive values that may be considered as subject to but little modification in the future. In their comparison of the results of the two methods they have used trignometric parallaxes for 657 stars. Omitting a few stars that present special difficulties in the application of the spectroscopic method, the average difference between values found by the two processes is only .001 second of arc—a difference comparing favorably with that found between the results obtained by different observers using the trigonometric method alone.

**Occultation of a Star by Saturn.**—The occultation of the star Leipzig I., 4091, by Saturn on March 14, 1920, was observed under favorable conditions at Mr. Reid's observatory, Rondebosch, near Cape Town. From the report of the observations published by Mr. Reid, it appears that certain phenomena were of striking interest; viz. (1) there was very little diminution of light when the star was behind the ring, and (2) the light of the star died out gradually before immersion, and on its reappearance the star seemed to be within the disk of Saturn. From the first of these facts, says the *Journal* of the British Astronomical Association, seeing that the ring is now turned to us almost edgeways, it would seem that the particles of which the ring is composed are either very much smaller or farther apart than they have heretofore been supposed to be. From the second observation the inference may be drawn that Saturn is a smaller globe than has been assumed, and that it is surrounded by an atmosphere of considerable extent.

**Color Changes on Jupiter.**—Writing in the *Monthly Notices* R.A.S., Mr. A. Stanley Williams deals at length with a recurrent change in the color of Jupiter's equatorial zone. This zone is normally nearly pure white. Toward the end of 1869, Mr. John Browning called attention to a remarkable change to a deep tawny yellow, and several attempts were made about that time to trace the history and possible periodicity of similar changes previously observed. With the observations since accumulated at his disposal, Mr. Williams finds that during the past 150 years there have been at least five occasions when the tawny color made its appearance in a very definite manner, viz., 1789, 1839, 1860, 1871 and 1898. Its visibility generally lasts about three years. It has recently reappeared, and was described last April as very conspicuous. Apart from this broad orange-colored band the planet is, at present, remarkably free from color. Taking into account certain less definite appearances, Mr. Williams finds a period of 11.95 years. This is so near the planet's period of revolution around the sun that the true period is probably identical with it. The tawny color makes its appearance a little before the planet reaches perihelion. The writer has found nearly the same period for changes in the color of the two dark equatorial belts. A connection with the sunspot period naturally suggests itself. This is generally supposed to be about 11.1 years, but it is noteworthy that Professor Turner, by harmonic analysis, has derived a period of 12.0 years for the interval 1860-1894 and also for the interval 1889-1919.

## Aeronautics

**Holland to Java Flight.**—The Dutch Government contemplates offering a prize for the first Dutch aviator who flies from Holland to Java. Three competitors have already offered themselves. Lieutenants Backer and Wullften Palthe, who will make the journey in a Vickers F-3, fitted with two Rolls-Royce engines, will fly from Amsterdam via Brest, Marseilles, the Piraeus, Basra, Karachi to Culcatta, and thence via Rangoon, Penang and Singapore to Batavia, in Java.

**Gordon-Bennett Cup Race.**—The French Aero Club will make the contest for the Gordon-Bennett Aviation Cup an occasion of considerable importance, according to all reports from France. The race is to be the principal event of an "Aviation Week," in which aviators from numerous countries will compete for prizes. Rumor has it that the United States has several surprises in store for the Gordon-Bennett race, among these a new engine of tremendous power for its weight. It would not surprise us if the American aircraft manufacturers were well represented; indeed, an American may even win the great contest if all we have heard about the new engine is true.

**Oxygen Heater for High Fliers.**—The Army is conducting tests on a new apparatus for heating oxygen at high altitudes, in order to prevent a recurrence of failure such as experienced by Major Rudolph Schroeder recently in his record climb. The apparatus consists of a refined thermostatic interrupter in connection with electric resistance coils, attached to the oxygen generator. The apparatus heats the oxygen as it leaves the exhaust valve of the container, and keeps it heated until it reaches the distributer. This prevents any moisture present from freezing in the delicate distributer, and it also heats the oxygen again before it enters the pilot's mask.

**Our Dirigible R-38.**—We understand that the American crew to be trained in England to fly back our monster airship, the R-38, has been selected. We hear also from England that the ship will be ready to commence her exhaustive trials fairly soon. It takes a long while to tune up an airship—there are so many balances to be perfected, apart altogether from engine trials and the like. The following figures which have not been published in this country before will give a fair idea of the dimensions of the R-38, in comparison with the R-34, which flew the double Atlantic journey last summer.

| | R-34 | R-38 |
|---|---|---|
| Length (in feet) | 639-5 | 695 |
| Capacity (in cubic feet) | 2,000,000 | 2,700,000 |
| Tonnage | 60-7 | 92-0 |
| Maximum Speed | 58 | 70 |

The German airship "Bodensee," to which so much publicity has been given, is more than one hundred feet shorter than the R-38, has a gas capacity of only 700,000, and is of 21-3 tonnage. It is claimed, however that her maximum speed is 80. Her main disadvantage is obviously her inability to travel great distances on account of her limited gasbag capacity.

**High Speed and High Altitude.**—Major Schroeder after his recent height record flight, made an interesting statement that he believed that at great heights—heights beyond those he has reached—it would be possible to make use of air currents and to fly at enormous speeds. Some French inventors now claim that in a few years it will be possible to fly at a height of 40,000 feet and maintain a speed of nearly 300 miles an hour. Mr. Kipling many years ago prophesied that in an aircraft all metal and of cigar shape we should hurtle through space at heights of rarefied atmosphere where there was practically no air resistance. What exactly the propellers would have to bite upon he did not disclose. But the French inventors have produced a mechanism which compresses the air in which the propeller rotates to normal atmosphere. The economic value of this invention is obvious, for the higher one goes the more quickly one travels and the quicker the journey is accomplished the less fuel will be used. On the other hand, if there be these furious air currents at very great heights as Major Schroeder hints, there will be insurmountable air resistance in some directions. By the way, someone recently referred to the gallant Major as the man who had fallen farther than anyone except Adam!

# Is There a Coal Shortage?

## A Survey of the Coal Question in Our Largest Coal-Consuming Center

By Harry A. Mount

*WE cannot get along without coal. Even in this enlightened age of hydro-electric developments, oil-fired boilers, gasoline engines, alcohol-burning devices and so on, coal remains the prime fuel of business and home alike. The recent rumors of an impending coal famine this coming winter have naturally caused great consternation far and wide. A coal famine would affect our industries, public utilities, railroads, steamship lines, homes, personal health—in a word, our entire national life. Truly, this is a grave question of the moment. We assigned the task of investigating the coal situation to Mr. Mount, and in the accompanying article he reports his findings. It appears as though there will be no coal famine, barring unforeseen events.*—THE EDITOR.

TAKE your watch from your pocket between five and six o'clock in the evening and count off sixty seconds. During that brief time seventeen tons of coal—nearly enough to fill one of the largest coal cars—has been shoveled under the boilers that furnish power to run New York City's network of subway, elevated and surface car lines, furnish electric power for lights, and supply gas for cooking. More coal is burned at that hour than at any other; but in a single day 15,000 tons are required for these three public utilities—transportation, electric current, and gas.

If all this coal were loaded on a single train it would stretch out more than five miles. This coal must arrive day in and day out, month after month with unfailing regularity. Much depends on it. If these utilities were left for a day without coal the great city would be utterly paralyzed and the effects would be felt in every corner of the land.

If the gas supply fails in a smaller community, one can rig up an oil or coal stove, or even find wood enough to cook the family meals; but imagine the result if each of the hundred or more families in a big apartment house each suddenly had to find coal or wood and proper stoves to burn it. Utter confusion would result if the whole city were suddenly cut off from its gas supply. And New York is not supplied with natural gas but with artificial gas, made from coal.

If a city the size of Cleveland or St. Louis finds its street car service suddenly shut off, the citizens usually can press busses or automobiles into service, or walk, and the city's business goes on. But even if enough busses could be found to carry New York's great throngs of workers, there would not be enough room on the streets for them. Transportation lines overhead and underground are absolutely necessary, for the streets are overcrowded with normal traffic.

If electric power is a great convenience in smaller cities, it is an absolute necessity in New York. Without it elevators would stop, many of the smaller industries would halt for lack of power, practically every light in the metropolis would be extinguished and almost countless other activities would cease. The tallest buildings would be without fire protection because steam fire engines cannot throw a stream of water to their tops and powerful electric motors are depended upon.

In short, should the coal supply of New York's public utilities cease the city would be completely paralyzed. Should the tie-up last for any considerable period the city's great freight terminals would become glutted with freight, which could not be loaded on boats. Since New York is the "neck of the bottle" for most of the country's export trade as well as a considerable part of the raw material which keeps our own factories in New England and coast points running, the effects of such a tie-up would soon be felt outside the city. Railroads which keep a steady stream of freight moving into New York would have to cease shipments and the freight congestion would soon extend far inland. Drastic measures would have to be taken to keep New England factories running and the extra freight cars needed in this effort would draw from the already meager supply and slow-up freight movement throughout the entire country. A long shut-down of New York's public utilities would start a cycle of calamitous events from which every man, woman and child in the country would suffer.

And then consider the strength of the thread upon which this continued service hangs. Because of the enormous quantities of coal used, and the lack of storage space on crowded Manhattan Island, no great reserve supply of coal can be kept on hand. Some of these utilities have no more than two weeks' supply even in normal times. Many of them have less at present. A steady stream of coal must pour into their bins from the mines or disaster is imminent.

We have heard much recently of an impending coal shortage. But so far as the public utilities of New York are concerned, there is no coal shortage at present. Executives of the largest companies agree that they can buy all the coal they need. Because their supply of coal must come in a steady stream, rain or shine, good times or bad, they are regarded as "A1" customers by the larger coal mines. As a rule the public utility companies buy independently at the mines. In some cases it is necessary to contract for more coal than is actually used, but on the whole an adequate supply is available.

Investigation shows that in the case of one or two small public service corporations which have complained bitterly of a "coal shortage," the real trouble is that they are unwilling to pay the present market price for coal and are living a "hand to mouth" existence in the hope that coal prices will drop.

It is true, however, that almost all of the large companies have not on hand a normal coal reserve. This is the result of cumulative causes rather than any sudden emergency. During the coal strike of last winter the reserves were depleted. The strike delayed shipments to the Northwest until the Great Lakes were frozen over and then shipments which would have been made by boat had to be made by rail. As a result many coal cars instead of making a four-day trip to Cleveland or Toledo, made four-week trips to Duluth. This drew heavily on the already inadequate supply of coal cars, adding to the uncertainty of deliveries to New York.

Then followed the influenza epidemic which had the effect of making deliveries still lower and more erratic. And finally, when traffic was getting back to normal, there came the "outlaw" rail strikes and the transportation system of the East was again tied in knots, many of which have still to be untied.

(*Continued on page 189*)

**Much has been said about the use of coal cars for transporting building materials. Here is undeniable evidence that such has been the case. This practice is in direct violation of the Interstate Commerce Commission's ruling**

## A Concrete Oil Tanker

THE launching of the 7,500-ton concrete oil tanker "Cuyamaca" recently took place at San Diego, Cal. The ship, which is shown in the accompanying illustration, is 434 feet long and as trim as any steel freighter. Just behind the "Cuyamaca" is a sister ship soon to be launched. The two tankers were built for the United States Shipping Board and have been chartered by the France and Canada Steamship Company. These two ships formed part of the Shipping Board's program for the construction of a fleet of concrete freighters. It has been announced that it is not the intention of the Board, at least for the present, to build any more of this type.

**Launching of the concrete 7,500-ton, 434-foot, oil tanker "Cuyamaca" at San Diego, Calif. This and a sister ship, shown astern in the picture, were built for the U. S.Shipping Board**

## The Contest for the Harmsworth Motor Boat Trophy

IN preparing for the 1920 contest for the famous Harmsworth trophy for motor boats—one of the most coveted of international trophies, American builders, profiting by past experience, constructed three boats of exceptionally high power in proportion to their size and weight, which were designed to meet the variable conditions at the course, which is laid off the Isle of Wight. We present illustrations of these three boats—"Miss America," "Miss Detroit V" and "Whip-po-Will, Junior."

It is needless to say that all three are of the hydroplane type, and each of them developed on trial speeds which made the prospects of our capturing the cup look very favorable. "Whip-po-Will," owned by Albert L. Judson, of New York, was the most powerful of the three American crafts, being driven by two Bugatti engines in tandem, whose combined horse-power is about 900. Unfortunately, during the preliminary tuning up of this boat on the day before the races, she caught fire and sank. The other two boats were designed and built by G. A. Wood, of Detroit, who more than any other man in this country has contributed to the development of hydroplanes of extremely high speed. Both boats have the same motive power, consisting of two reconstructed Liberty engines, driving separate propellers, the combined horse-power being about 800. The faster boat of the two, "Miss America," is a craft of extremely small dimensions, considering her great horsepower. She is twenty-six feet in length by seven feet in beam. Experience on the other side has shown that a boat of such dimensions and speed is at a serious disadvantage in the choppy seas which are liable to be experienced on the Isle of Wight course, and accordingly Mr. Wood built another boat of the same horsepower and driven by the same type of engine as "Miss America," but considerably larger and more seaworthy. This boat which he named "Miss Detroit V" is 38 feet long and 8 feet in beam. It was known that some of the foreign competitors would probably build up to the limit of length at forty feet, and Mr. Wood figured that, with his two boats in the race, he would be prepared to meet whatever weather conditions might be found on the day of the race.

**"Miss America," built and owned by G. A. Wood of Detroit, Mich. Winner of the Harmsworth Cup. This little craft, 26 feet length by 7 feet beam, is driven by two 400-H.P. Liberty motors**

The course of thirty miles was covered in five rounds of six miles each. As competitors the two American boats had "Maple Leaf V" and "Maple Leaf VI," owned by Sir Mackay Edgar, and "Sunbeam Desenjol," which belonged to Mr. Coat Allen. In the first race "Miss America" came in first, having covered the thirty miles at an average speed of 51.45 knots, her fastest lap being covered at the rate of 56.63 knots. "Miss America" covered the course in 38 minutes 17 2/5 seconds; "Maple Leaf VI," second, in 41 minutes 30 seconds; the third boat, "Sunbeam Desenjol," took 43 minutes 30 seconds; and "Miss Detroit V," the fourth in line, required 46 minutes 12 3/4 seconds for the thirty miles. The comparatively slow time of "Miss Detroit V" is due to the fact that she developed engine trouble in the fourth round, and after that she was unable again to maintain her maximum speed. "Maple Leaf V" also had engine trouble and had to retire from the race, which put "Miss Detroit" in the fourth place.

The second day's race was also won by "Miss America," with "Miss Detroit V" in second place, "Maple Leaf V" third, and "Maple Leaf VI" fourth. The time of "Miss America" for the thirty miles was 37 minutes 5 1/3 seconds, and her average speed was 53.42 knots. Her highest speed, made during the first lap, was 56.41. "Miss Detroit V" took 37 minutes 43 4/5 seconds to cover the course, and "Maple Leaf V" took 37 minutes 59 seconds. "Maple Leaf VI" was fourth and "Sunbeam Desenjol" fifth.

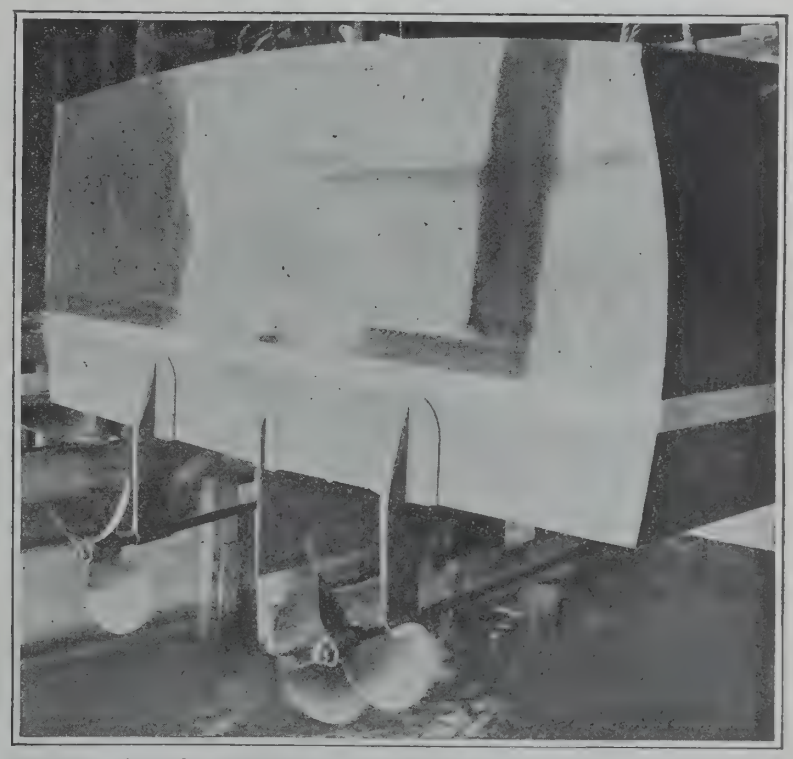
The Harmsworth Cup comes once more to America, and as Sir Mackay Edgar, owner of "Maple Leaf V" expresses his purpose to build a faster boat and try again, we may see another race for the Cup next year, probably on the Detroit River.

## Oil, Sugar and Alcohol from an African Tree

THE sump tree or *Balanites aegyptiae* Del., five or six million tons of whose fruit are gathered annually in Senegal, is a variable source of oil, sugar, and alcohol. The fruit consists of an oleaginous spindle-shaped kernel enclosed in a hard fibrous shell and surrounded by sweet pulp containing a very high percentage of sugar and enclosed in a tough skin. The kernel contains 41.80 per cent of fats and 25.32 per cent of nitrogenous substances. However, the shell is so difficult to crack that only the pulp can be at present considered useful for industrial exploitation. This pulp contains sufficient fermentable material to hold from 9.7 to 10.8 cm. of sugar per 100 gr. of fruit. The composition of the fruit is as follows: sweet pulp, 42.9 per cent; shell, 48.3 per cent; oil bearing kernel, 8.8 per cent. The sweet pulp contains 40.3 per cent sugar.

**"Miss Detroit V," built by G. A. Wood. Length 38 feet; beam 8 feet. Driven by two 12-cylinder, 400-H.P. Liberty motors**

**"Whip-po-Will Jr.", owned by A. L. Judson, N. Y., is driven by two 16-cylinder, American-built Bugatti motors, in tandem. Horse-power 900**



**The stern view of "Miss Detroit V," showing method of supporting the twin, 3-bladed propellers, on each of which 400 horse-power is developed**

# An Engineering Bulwark

## The Proposed Standing Army, for Purposes of Peace, of the Men Who Know How to Do Things

By Richard L. Humphrey

THE average citizen in this country has little knowledge of the work of the engineer. To him the word "engineer" means the man who runs a locomotive or some other steam engine, or in some cases he recalls that his plumber has under his name "Sanitary Engineer." He does not associate with the engineer the great transportation systems of the country, the street railway service, the telephone and telegraph, the office buildings, the water supply, the sanitary disposal of sewage, the lighting systems, the street pavements and highways, proper housing and town planning, to say nothing of the bridges and other structures that safely carry millions of people, all of which are daily necessities. Nor does he realize or appreciate the fact that the marvelous development of this country and of its resources has been an engineering achievement in which the engineer has been a pioneer.

During the war the engineer came into a prominence hitherto unknown by reason of the fact that he was essential to the winning of the war and it early became apparent that the engineer was doing yoeman service. It is no disparagement of the bravery of the flower of the American people who fought in France and Flanders to say that their work would have been of little value had they not been supplied at the critical moment with the vital munitions of war. The brilliant work of the engineer in providing Europe with harbor, transportation, housing, commissary and telephone facilities is a matter of common knowledge; and this is also true (though to a lesser extent because more removed from the theater of war) of the tremendous work done in producing ammunition, guns, airplanes, locomotives and cars for the transportation of these munitions of war in this country as well as in Europe; and particularly is this true of the ships which were so vital a factor in the feeding of the American Expeditionary Forces. The spectacular building of ships has been one of the wonders of the world. During this time it became evident to the public that the engineer was a prime factor in this achievement.

The war, therefore, created in the mind of the public a greater appreciation of the services of the engineer and created in the engineer a greater desire for service. The needs of the Government for engineering assistance during this crisis led to the creation by the four great National Societies, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, of an Engineering Council to provide a medium "for the consideration of matters of common concern to engineers as well as to those of public welfare, in which the profession is interested, in order that united action may be made possible." In February, 1919, and in April, 1920, the American Society for Testing Materials and the American Railway Engineering Association became respectively the fifth and sixth members of this Council.

Among some of the things that this organization has accomplished may be mentioned:

1. Furnished to Government departments four thousand names of engineers for technical duties; aided the Naval Consulting Board and the Army General Staff in examining 135,000 suggestions and inventions for war devices, and coöperated with the Fuel Administrator and the Bureau of Mines in conserving coal;

2. Helped secure exemption of engineering students from military service until the completion of their technical training;

3. Organized the Engineering Societies Employment Bureau in November, 1918, which since the armistice has registered 5,500 engineers and assistants, mostly returned soldiers and naval men, and has aided thousands to positions without charge;

4. Through a direct appeal to President Wilson, Council brought about a conference of fourteen different Government offices, engaged in map making, with the prospect of greatly accelerating the completion of the topographical map of the United States. It is now hoped to have the whole country mapped in a decade and a half; at the former rate, the Twentieth century would have ended before the map was finished.

5. Established an office in Washington January 1, 1919, under the general direction of the National Service Committee. Through this office engineers have been put in contact with the Federal Government as never before, individuals, companies, and societies have been furnished information about the activities of Congress and the departments of the Government, and useful services have been rendered to the Government;

6. Joined with National Research Council in a report on and improvement of the Patent System and Practice, on which legislation has been passed;

7. Participated in organizing the National Board for Jurisdictional Awards in the Building Industry and has a member thereon;

8. Sent delegates to Washington on the invitation of a Committee of the House of Representatives to present testimony before the committee in favor of a national budget;

9. Has recently organized a Committee on Types of Government Contracts;

10. Is studying the curriculæ of engineering schools, and making suggestions as opportunity offers;

11. Assisted the State of New York in preparing a scheme for organization of State Government.

As a result of the war experience, the American Society of Civil Engineers, in June, 1918, authorized the appointment of a Committee on Development by a resolution, the preamble of which was in part, as follows:

"Sociological and economic conditions are in a state of flux and are leading to new alinements of the elements of society.

"New conditions are affecting deeply the profession of engineering and its service to society in its various relationships to communities and nations, and in its internal organizations.

"A broad survey of the functions and purposes of the American Society of Civil Engineers is needed in order that an intelligent and effective readjustment may be accomplished so that the society may take its proper place in the larger sphere of usefulness now opening to the profession. . . .

"Any changes in organization must take into account all the conditions above indicated, and also the relationship of the American Society of Civil Engineers to other engineering organizations and to the public."

Similar committees were subsequently appointed by the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, and the American Institute of Mining and Metallurgical Engineers. The problem of these committees concerned both internal relations and external relations and in dealing with the latter, conferees were appointed from the four societies, which met in August of 1919 and organized the Joint Conference Committee. Its report in September of that year recommended "the formation of a single comprehensive organization to secure united action of the engineering and allied technical professions in matters of common interest to them" and at the joint meeting on January 23, 1920, of the members of the governing boards of the four societies, of the American Society for Testing Materials, of the members of the Engineering Council and the Trustees of the United Engineering Society, unanimously requested the Joint Conference Committee to call without delay an Organizing Conference of representatives of the national, local, state and regional engineering organizations of the country for the purpose of bringing into existence the comprehensive organization recommended by this committee.

In compliance with this request the Joint Conference Committee issued a call, in response to which there convened in Washington one of the greatest conferences of engineers in the history of this country. There were present one hundred and forty delegates representing seventy-one engineering and allied technical organizations having an aggregate membership of upwards of one hundred and twenty-five thousand. The spirit of the conference and the unanimity of purpose expressed in the formation of The Federated American Engineering Societies and the adoption of its constitution and by-laws without a dissenting vote, clearly indicates that the engineer had been aroused as never before to a sense of his responsibility as a citizen; and there was a constant expression of his desire for unselfish service in the common weal.

At that historic Washington Conference was laid the foundation for the greatest engineering organization in the world. When formal invitations to become members of The Federated American Engineering Societies had been a week in the mail, the aggregate membership of the societies that had already accepted make it the greatest engineering organization in this country and before the American Engineering Council meets it will be the greatest engineering organization in the world.

The prime underlying purpose of the organization is unselfish service to the public. That it is not organized for selfish purposes is indicated in the preamble to the constitution which is as follows:

"Engineering is the science of controlling forces and of utilizing the materials of nature for the benefit of man, and the art of organizing and directing human activities in connection therewith.

"As service to others is the expression of the highest motive to which men respond and as duty to contribute to the public welfare demands the best efforts that man can put forth, now, therefore, the engineering and allied technical societies of the United States of America, through the formation of The Federated American Engineering Societies, realize a long cherished ideal—a comprehensive organization dedicated to the service of the community, state and nation."

The organizing conference in Washington entrusted the Joint Conference Committee with making provision for putting the conclusions of the conference into effect and authorized it to act as an ad interim committee between the adjournment of the conference and the first meeting of the American Engineering Council.

Engineering Council at its meeting in June heartily endorsed The Federated American Engineering Societies and the American Engineering Council and authorized:

"Its Executive Committee to proffer and perform on the part of Council such assistance as may be practicable in completing the work of the Organizing Conference and of the Joint Conference Committee of the Founder Societies in establishing the American Engineering Council."

The activities of Engineering Council will be formally taken over by the American Engineering Council January 1, 1921. One of the important matters started by Engineering Council, which will be carried on by the American Engineering Council, is the movement to create a National Department of Public Works, which has crystalized in a bill now before Congress, known as the Jones-Reavis Bill, for the establishment of a National Department of Public Works by modification of existing departments. This bill, by concentrating the engineering and construction activities of the Government in a single department, will effect an annual saving of a very considerable amount, will eliminate duplication of effort, and so coördinate the work as greatly to increase its efficiency and place the construction of public work on a business basis, by which it may be done more efficiently both as regards its cost and time required for its completion. This movement is entirely in accord with an effort to secure a national budget in which effort Engineering Council has partici-

(*Continued on page 190*)

*CONSTANT repetition weakens as well as strengthens, and it is an old, old story what the engineers did in the great war. Perhaps it is not generally realized, however, that much of this achievement was due wholly to the manner in which the engineering resources of the country were mobilized under a single direction. The question now is in order, to what extent are we to see this temporary organization abandoned and to what extent are we to insist that if a thing is good in the war emergency it is good in the routine of peace? Some of the responsible heads of the engineering profession are trying to answer this question on the side of efficiency, and to preserve as a permanent asset the marvelous organization which enabled the American engineer to function so far beyond the fondest expectations during the war. That in a word is the story of the Federated American Engineering Societies, of which Mr. Humphrey, Chairman of the Joint Conference Committee, tells us here.*—THE EDITOR.

# Reclaiming Salt Surfeited Soils

## How a Western Problem Arising Out of Irrigation Methods Is Being Met

By George A. Dacy

MILLIONS of acres of potentially fertile and productive land—adapted propitiously for the growing of staple crops—are lying idle throughout the wide stretches of the plains and valleys of the arid and semi-arid West because they are "alkali" sick. Peculiarly enough many of these ailing soils are on the invalid list because they are surfeited with chemical salts for which many of the eastern farmers pay high prices in the form of commercial fertilizer. As it is, however, the alkali lands are so rich in their content of chlorides, sulfates and carbonates of sodium, as well as in their less bountiful reserves of calcium, magnesium and associated materials, that they are rendered unfit for cropping service due to the fact that the plants cannot survive under such conditions.

The spread of the alkali sickness is largely accomplished by the use of irrigation water as the moisture supply artificially applied in the regions of restricted rainfall is so rich in these soluble chemical salts that its continued use ultimately results in so amply stocking the fields where the irrigation water is applied with these chemicals that they become temporarily useless for further cropping purposes. As a consequence it is necessary for the irrigation farmers to exercise the greatest care and precaution relative to their water supplies. Once a western irrigated field becomes over-stocked with alkali, the only practical method of eliminating the obnoxious chemicals is by flooding the land with uncontaminated irrigation water which will carry away the objectionable and soluble salts. The usual practice is to dig deep ditches which empty over rough, untillable land and which deposit the drainage waters containing the obnoxious salts far enough away from the productive fields to reduce their potential powers of further contamination.

Farmers who wish to purchase agricultural land in the western States of Arizona, Kansas, Nevada and adjoining territory are always anxious to ascertain the alkali susceptibility or content of these soils. Similarly it is fundamentally important to find out definitely the chemical composition of various tracts of land adapted for future irrigation. It has long been desirable that some simple, economical and practical manner of testing these soils for alkalinity be devised. Uncle Sam has been vitally interested in work of this character and the investigations and resourcefulness of the scientists in his employ have been responsible for the inception of a practical test of utmost accuracy.

The Government experts have harnessed the Wheatstone bridge—familiar to all students who have studied physics—for this work. Each national soil surveyor who is engaged in soil mapping and survey work in the western country where alkali soils prevail, now carries a portable salt bridge of this description as one of the most valuable tools in his scientific outfit. The bridge is an electric resistance box in which three of the resistances are known, while the fourth is the one to be determined. A soil auger is used in obtaining a small core of soil which is then washed in a small container in order to extract the soluble salts. The solution is then transferred to a small resistance cup which is placed on the Wheatstone bridge. The operator holds a telephonic listening device to his ear and simultaneously moves the dial hand on the electric resistance box backward and forward until he strikes the point where only a slight murmur is discernible. He then reads the dial and correctly reduces the reading to parts per million of soil by reference to a standardized resistance table which is used with the salt bridge. This figure gives him the alkali content of the soil tested and indicates its adaptability for irrigation and crop production activities.

Any farmer or landowner can operate the salt bridge. It is simple and does not require the services of a scientific expert for the performance of the soil test. The simplicity of the device greatly extends the field of its practical application. It has already proved to be a prize first aid instrument in the soil survey work which the Government is performing in the arid and semi-arid regions. The farmers, ranchers, real estate agents, land buyers and irrigation promoters are also coming to appreciate the great value of this ingenious device in eliminating the gamble from their operations. Hence they are now only making wider use of this scientific test while they also are paying more attention to the reports which Uncle Sam issues officially as the result of the soil survey and mapping operations which he is supervising in the districts under discussion.

Usually in the alkali sections the runoff water from the hills accumulates in the valleys where the moisture evaporates and the salts remain. The Great Salt Lake is an example of such salt concentration. In many instances irrigated farms at the higher levels disseminate the alkalinity of the soil to places below them in the runoff irrigation water. The obnoxious condition of salt concentration and centralization is also spread by the rise of soluble salts in the ground water. Where the water table rises in this manner, alkalis which are deep-seated in the soil are often brought nearer to the surface with the resultant limitation of plant growth.

Throughout the agricultural and irrigated sections of many of the western States, the accumulations of alkali in the soil and on the surface are so pronounced as to blind temporarily those who look at the glittering, white stretches of soil. The farmers of these regions are in many cases exposed to the danger of alkaline accumulations in the soil handicapping their cropping operations, while in instances where such salt contamination does not occur, dry weather and the restricted supplies of irrigation water may seriously curtail annual production. Even after a farm is freed of its excess of alkali, the owner has to practise persistent and complete precautions to prevent his acreage from again reverting to a barren waste. However, the prodigal productivity and fertility of these reclaimed salt soils usually make it worth the farmer's effort to rid them and henceforward to keep them free of these soil-ruinous salts.

### "Unless Human Nature Is Changed"

To the Editor of the SCIENTIFIC AMERICAN:

In your June 12th issue you quote from the purported word of Lenine to the effect that human nature must be changed before the economic system under which it operates can be changed and yourself imply agreement with the statement. It is questionable that Lenine ever made such a statement. He seems too well read and practical a man to make an assertion antithetical to the facts of history. But the authorship of the statement is immaterial. It is the statement itself that is under analysis. It is a stock argument of capitalism.

It is generally conceded—and you yourself have so conceded in former editorials—that human nature is unchanged since the beginning of history. The world has had four economic systems in that time—chattel slavery, feudal slavery, competitive slavery (or system) and wage slavery (capitalism). In the first the master owned the slave bodily; in the second he owned the land upon which the slave worked and the slave could not leave the land without permission of the master, and was sold with it when it was sold; in the third the slave through the quarrels of the masters, gained sufficient freedom to permit him to fight (compete) with his fellow slave, individually in their respective lines of work, to supply the demands of the masters; in the fourth—capitalism—the master owns the job and the slave is permitted to change masters *ad libitum*—provided his purse will permit. Each of these economic systems is, relative to the slave, an improvement over its predecessor.

Human nature did not change in the transit from chattel slavery to serfdom, neither did it change when serfdom was cast aside and the competitive system adopted, or yet when capitalism came, almost like a flash, human nature remained the same.

History will repeat: "Human nature" will continue to throw off its obsolete systems and adopt better ones—and this is just what Russia—not Lenine—has done.

Lenine is not seeking to "lead" into a "land of the golden rule" as you assert. He simply recognized the fact that the old order—rather disorder—has served the time of its usefulness, that the world is ready for the new.

Your assertion that the Russian movement was an "overnight" affair is incorrect. It had been growing at least half a century. With equal untruth it could be said that the bursting of a seed pod to liberate the ripened seeds within is an "overnight" development. The fact is the obsolete pod was forced to burst by the seeds grown, ripened and ready for the change and demanding opportunity to manifest new life. So it is in Russia—so it is the world over, but elsewhere the "pod" has not been forced to burst.

Lakeside, Wash. WILL A. ROBISON.

To the Editor of the SCIENTIFIC AMERICAN:

I am glad to find the problem of human nature and the social order discussed in a scientific journal, for it is a problem in social science.

Our prevailing difficulty—that not mere scientists but even philosophers seem unable to get around—is to appreciate, first, that the "established order" is basically a survival of pre-historic anarchy in its anti-social spirit and practice; second, that human nature is not taken into account by this "order," with any view to its betterment or social efficiency; third, that were human nature the ideal thing that is commonly supposed to be a prerequisite to a perfected social order, then such a perfected social order would not be an urgent matter; we would get along comfortably together under the pure anarchy that doubtless prevailed ten thousand years ago.

It is chiefly because human nature is so very human, finite, selfish, generous, foolish, crafty and otherwise an uncertain and disproportionate quantity that a perfected social order that Russia has sought over-night, and that our own Bellamy so wisely envisioned, has been the pressing need of the last hundred years.

There has been a vast hitching up of the cart ahead of the horse, or the trailer ahead of the motor, in this discussion; for the stock objection to the establishment of business of, by and for the people has been the parrot phrase, "you can't change human nature."

In this same issue of June 12th an inventor offers yet another form of rotary motor, the ideal in steam prime movers, without making provision for any change in human nature! And therein is discussed new methods for the finishing of cement surfaces with a view to ideals in plastic artistry, and no provision whatever has been made for the conversion therewith of the human nature of cement workers!!

You can't change human nature, therefore you can, and eventually must, change the social order so that the best in human nature may be developed and rewarded, and the worst in human nature discouraged and eventually dissipated; because under such an "ideal" social order it will pay both in material and moral rewards to be good, honest, industrious, modest.

And that order—let me hasten to say—does not involve the abolition of capitalism, as our radical friends feel "ordained and called to preach"; but its installation, as the beneficent invention for the overcoming of pre-historic anarchy that it is, as a national and international function of, by and for the people—a government that will govern—to the public and the private profit.

Human nature is not so very bad; all it needs is a fair chance. It has never had it. A. GEORGE.

Hollywood, Cal.

### Power from the Past

To the Editor of the SCIENTIFIC AMERICAN:

A general reader turned away from the article by C. H. Claudy, Vol. CXXII, p. 700, by its tiresome repetition of a teaching of M. Thomas Cot about "heat long ago stored for us," etc. Thinking twice would have convinced Mr. Claudy that the energy manifested as the heat of an ordinary fire was located immediately before the fire in the oxygen of the burning reaction. If this energy was put into the oxygen by the sunlight it was done when at the leaf surface, the $CO_2$ containing comparatively little energy, was decomposed into oxygen containing much greater energy and carbon with little if any energy. The energy thus going into the heat of the fire may as well have come from the sunlight at a nearby maple leaf, a movement before, as from the sunlight of the "prehistoric days when the coal beds were being formed."

Chicago, Ill. FRANCIS B. DANIELS.

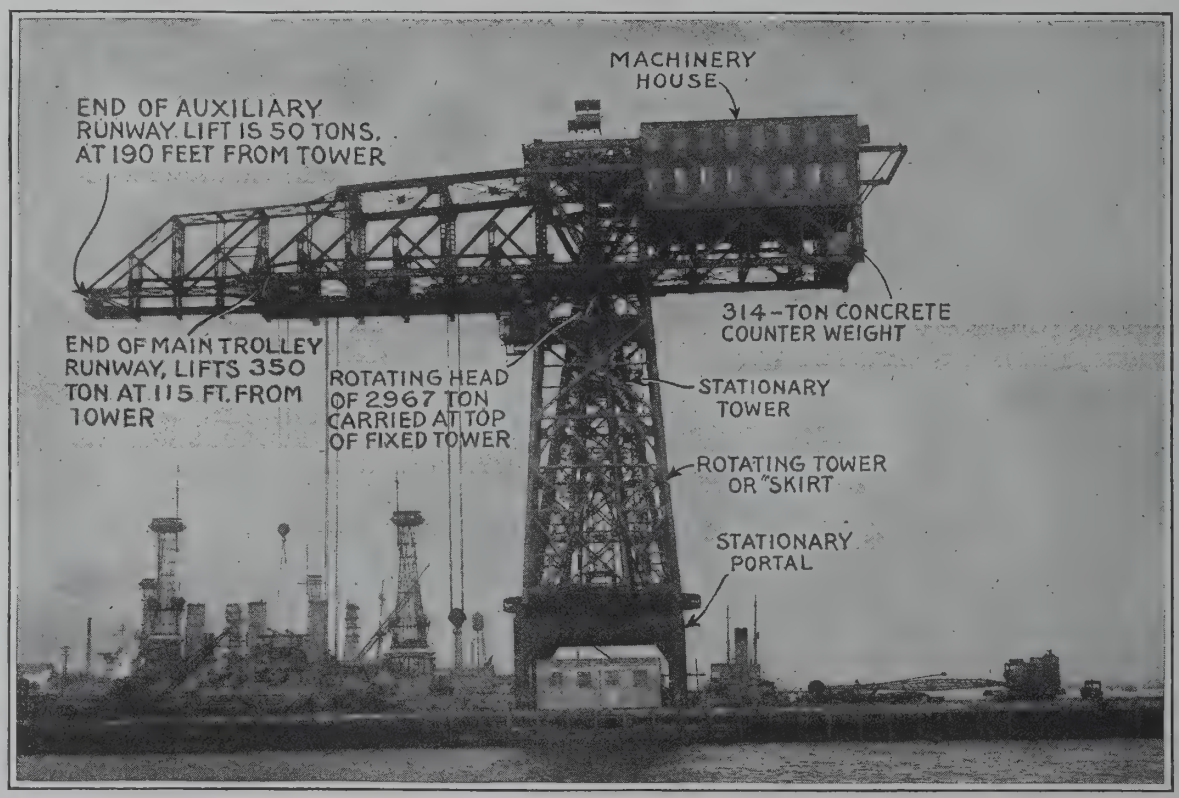
# The World's Largest Crane

## How the Engineer Has Made It Possible to Lift and Swing a 350-Ton Load

THE reasons which prompted the construction of the enormous crane that forms the subject of this article are to be found in the ever-growing size and weight of the elements which enter into the modern dreadnought, and in the desire during the construction and repairs to handle these elements as a whole instead of disassembling them in order to render their lifting and transportation more easy. Thus, for instance, it has been found that in building a battleship time may be saved and the whole work facilitated if the turrets with their handling rooms are erected on the dock and placed aboard the ship in a complete condition. This, of course, means the handling of very heavy weights, particularly in the case of such a ship as the "Pennsylvania" and her class, in which three 14-inch guns are mounted in a single turret. These three guns together will weigh over 300 tons. It is customary, however, to handle the guns independently of the turret, either when the ship is being constructed or when the turret may have to be removed for repairs, but we have already adopted the 16-inch gun, weighing about 125 tons and the weight of armor carried on the turrets for such guns will be heavier than that used in previous ships. So it was decided to build a crane which would be capable of lifting out of a ship a turret with its handling room attached, placing it on shore for overhauling or repairs, and re-transferring it to the ship.

This, the world's largest crane, with a capacity of lifting 350 tons on a reach of 115 feet and 50 tons on a reach of 190 feet, has been built upon a dock which extends from the bulkhead line out toward the Delaware and serves two outfitting basins. Its extreme height is 230 feet, and during its test for acceptance, its load reached a maximum of 980,000 pounds. The total weight of the rotating part of the crane with its maximum load is 5,834,000 pounds, and the total weight of the whole steel structure resting upon its pile foundations is 4,000 tons. The total cost of the crane was $871,000, and of the foundation, $120,000.

However, the mere setting down of these cold figures upon paper, and even the photographic presentment of this great work, fails to give an adequate impression of its stupendous size. It is only when one stands beneath it on the dock and climbs the steps of the central stairway to the platform 200 feet above the dock, that an adequate sense of the immensity of this great framework of steel is realized. There are other extremely large cranes of this character in the world, it is true, one in England and another in Hamburg; but the Hamburg crane, for instance, has a maximum lift of 250 tons as compared with the 350-ton lift of the Philadelphia crane.



**General view of the giant 350-ton hammer-head type crane, 230 feet in height, at the Philadelphia Navy Yard**

The design of the crane was submitted to the Navy Department by the McMyler Interstate Company, and the final design was worked out in coöperation with the engineers of the Bureau of Yards and Docks. It is of what is known as the hammer-head type. The total load of 4,000 tons is carried upon an elaborate pile foundation, which is driven well down into the gravel below the overlying mud, and a lateral support to the foundation is given by a cofferdam fill. Upon this foundation was first erected the massive four-legged plate steel structure which is known as the stationary portal, the four massive legs of which support a system of deep, plate-steel girders which receive and distribute the superincumbent load. Upon the portal has been erected a central octagonal tower, the legs of which are very thoroughly braced together. This tower is finished in a plate-steel head, surmounted by a massive cast-steel cap. At the top of the cap is a turntable, consisting of a nest of horizontal steel rollers, which carries the weight of the rotating part of the structure, amounting to 5,834,000 pounds. The steel rollers are four inches in diameter, and the load works out at 3,800 pounds per inch of diameter by inch of face.

The rotating portion of the crane consists of an outer rectangular frame, known technically as the "skirt," and the overhead girders with their counterweight operating tower, runways, trolleys and hoisting cables. The skirt and the cantilever trusses are built integrally, and move as a single mass.

Now it will be evident from this description that when the crane is under load there will be a heavy overturning movement in the direction of the load, and this will result in a heavy horizontal pull at the top of the tower against the side opposite the load, and a heavy thrust against the bottom of the tower on the side facing the load. At the top of the tower the load is transferred from the moving to the stationary part by means of a nest of vertical steel rollers encircling the head of the fixed tower. These are enclosed in the same case C, as contains the nest of horizontal rollers carrying the vertical load, as above referred to. The horizontal thrust of the base of the skirt against the base of the tower is transferred from the one to the other by means of chains of vertical steel rollers. Each roller is journalled at its upper and lower ends in the links of a chain, the ends of which are secured to the bottom of the skirt or rotating tower. The rollers are carried in chains in order to secure an even distribution of load, and we are informed that the arrangement is giving the greatest satisfaction.

For lifting the heaviest weights, use is made of an equalizer bar, which carries a huge double hook at its center, and is provided with a pair of rings at each end which are engaged by the hooks on the right and left hand hoisting blocks and cables. Each of the two hooks has a lifting capacity of 175 tons, and the hook at the center of the equalizing bar has a capacity of 350 tons. The main hoisting cable leads up to two overhead trolleys, right and left. These trolleys are each carried on eight wheels and they travel over two runways extending from the tower out to the end of the main trusses, giving a reach of 115 feet. There is a third supplementary runway, which is carried by a supplementary and lighter truss extending beyond the main truss. This trolley has a capacity of 50 tons, with a reach of 190 feet.

The outboard section of the cantilever trusses carries at the outer end of its floor a concrete counterweight of 314 tons. The upper part of this section of the truss is occupied by a large two-story machinery house, in which are the 85 horse-power motors, gears and winding drums for operating the hoisting and racking cables. This operating house is itself 200 feet in the air, and is equipped with a 35-ton crane for handling the operating machinery.

An extremely interesting development, during the official tests of the crane, appeared when the four powerful hydraulic jacks at the four corners of the portal, placed there for the purpose of lifting the rotating portion of the crane, were tested out. For it developed as the pressure was increased in the pumps that, before the superincumbent mass was lifted, there was a total compression in the corner legs of the tower of 1½ inches due to the elasticity of the steel. The load lifted was just under 3,000 tons.

### Sunstroke in Trees

EVERYONE has noticed that a very hot summer frequently causes the early withering and falling of the leaves of trees, especially of those planted in streets of cities. A much greater injury is frequently done, however, by the superheating of the bark, which is far less obvious to the casual eye. It is not too far-fetched, perhaps, to consider such an injury as a sort of "sunstroke" like that which men and animals suffer from. This sort of scorching, when it occurs, is always upon the lower part of the trunk, partly because the trunk is here thickest and, therefore, most readily heated, and partly because the cooling effect of evening is felt latest upon that part of the trunk. Pine trees and beeches growing on the edges of forests shield their trunks by a protective screen of downward hanging branches. It is often supposed that the branches of these border trees grow in this manner simply because there is more room than in the midst of the woods, but it is really a case of protective growth. Other means of protection employed by the trees against this burning effect or strong sunlight is the formation of thicker bark and a stronger layer of cork cells. These protective measures are not employed, however, by trees growing in damp locations, where uncommonly high temperatures rapidly fall when evening comes.

The substance of the wood is actually killed by this superheating of the bark, even if it only occurs in comparatively small spots; it is, nevertheless, a very serious matter, since it causes the bark to split and tear thus forming places where insects and fungi can freely enter the wood and begin their work of destruction.

This burning of trees usually occurs not during the noonday hours but in those of the afternoon, and the southwest side of the trunk is the part most often affected. A German investigator, Mr. R. Hartig, who has studied this question, according to an account in *Kosmos* (Stuttgart) found upon examining an eighty-year-old pine tree growing in the open, on an August day when the temperature was 37 deg. Cent. in the atmosphere that the living substance of the wood upon the southwest side of the tree had a temperature of 55 deg. Cent., whereas the south side was fully 10 deg. lower; the northeast side had the lowest temperature, only 36 deg. Cent. This observation involves an important principle in horticulture, namely, that when trees are transplanted they must bear the same relation to the point of the compass as they did in the original location. It is sometimes advisable to shield saplings in the summer by binding straw about their stems until the roots have taken thorough hold in the ground and the crown is well furnished with foliage.

All of which conveys the thought that the transplanting of trees is just as delicate an operation as that of transplanting the usual run of plants, despite the difference in size and the apparent difference in ruggedness. Nurserymen would do well to give this matter careful study and considerable research.

# Record Weather

## Excessive Precipitation, Temperature Extremes, High Winds, Blizzards, Hurricanes and Tornadoes

By Wendell M. Whiting

DURING the forty odd years that Uncle Sam has kept accurate records of the weather and received information of meteorological phenomena from all over the world there have been gathered some exceedingly interesting, remarkable and startling data.

Along the coasts of this country and also in the interior there have raged some very violent and devastating storms with winds of such great force that in many instances there could be obtained no record of the highest velocity reached because of the fact that the anemometer was blown away or destroyed.

In this hemisphere there are four types of storms that often, but not always, cause very high winds. They are popularly known as cyclones, tornadoes, hurricanes and blizzards. Tornadoes and hurricanes are at all times severe, but cyclones and blizzards need not and do not necessarily bring winds of dangerous force.

The wind velocity during the height of the average western blizzard ranges from 30 to 50 miles an hour. While a gale of that force with a temperature often far below zero is something to be avoided, nevertheless it does not rip and tear and destroy as in the case of hurricanes and tornadoes.

**Pensacola hurricane, September 27, 1906. Baylen Street wharf looking southeast; also wrecked ship wharf across the slip**

The most severe eastern blizzard was probably the famous one of February 11, 12, and 13, 1899. The most remarkable feature of this unusual storm was that it affected a region of the country where mild winters are the rule and severe snow storms are decidedly the exception. The States to suffer most from the elements of this storm were Virginia, Maryland, Delaware and the District of Columbia. At Washington, D. C., the lowest temperature ever recorded in that city occurred—15 degrees below zero, and the snow was between two and three feet deep with drifts anywhere from five to fifteen feet in height. Records for low temperatures were broken all over the eastern part of the country, from the Gulf coast to New York City. The wind velocity during this storm did not exceed 40 miles per hour at any time.

In the West there have been so many severe blizzards with extremely low temperatures that it is difficult to pick out any one particular storm that was worse than any other. The great blizzard that swept over the Dakotas, Kansas, Nebraska, and Minnesota on January 11 and 12, 1888, was surely as severe as any. The storm swept down suddenly from the Canadian northwest, following a very mild day and without any warning whatsoever. Several hundred lives were lost and thousands of cattle perished. The wind blew at a rate of nearly 60 miles an hour, accompanied by a thick, blinding snow and a temperature around 20 degrees below zero. At Helena, Montana, the temperature fell fifty degrees in four and one-half hours. At Crete, Nebraska, it dropped eighteen degrees in five minutes.

The West and South is the home of tornadoes. They are without a doubt the most destructive and terrifying storm we have in this hemisphere and perhaps in all the world. Tornadoes come with such suddenness that there is absolutely no opportunity to give any warning. They last only a few minutes and disappear as suddenly as they begin. They occur most often from four to five thirty o'clock in the afternoon, which is generally the hottest time of the day. April, May and June are the months of greatest frequency. The States to suffer most from these death-dealing freaks of nature are Illinois, Missouri, Iowa, Kansas, Alabama, Georgia, Mississippi, Texas and southern Minnesota. Tornadoes never occur in any of the far western States. Indianola, Tex., was twice wiped off the map by tornadoes—first during the early summer of 1875 and again on August 19, 1886.

Most people do not have a clear understanding of the difference between a cyclone and a tornado. A vast system of winds blowing around a center of low atmospheric pressure is known as a cyclone. Many disturbances of this character pass across the United States at intervals of a few days, in a general direction from west to east. They are quite commonplace storms and as they approach the temperature generally rises. After they pass cooler weather follows with west and northwest winds. Sometimes these winds reach a high velocity, especially if a very high pressure area follows the cyclone. Very high northwest winds frequently follow these storms in the region of the Great Lakes, during the winter months, and quite often there is considerable damage done to shipping.

The most conspicuous feature of the tornado is a whirling black cloud, in the midst of a mass of dark storm clouds. This cloud is usually shaped like a funnel but at times looks somewhat like a balloon. Its action is similar to a waterspout. It sweeps over a narrow path never more than half a mile wide and often only an eighth of a mile in width. Wreck and ruin, death and destruction are accomplished by the terrific forces of the whirling winds wherever this funnel-shaped whirlwind sweeps the earth. These storms are purely local, while cyclones cover a very large area and travel for thousands of miles across the continent. Tornadoes are quite often called cyclones, but this is a mistake for they have no resemblance to a cyclone at all.

**Houses wrecked and the debris carried to the northeast by tornado at Binghamton, N. Y., June 5, 1905, at 10.30 P. M. This time of occurrence is unusual**

The West India hurricane is the other type of storm that causes great devastation. The West Indies and the Atlantic and Gulf coasts of the United States are the regions to suffer most from these storms. They originate way down in the West Indies, from whence they get their name. They only occur from July to October. Because of the splendid system of warnings established by the Weather Bureau these storms are always kept track of, and never arrive at our coasts without at least 48 hours' notice. They generally follow one of two courses—either up the Atlantic coast, or along the Gulf coast and thence inland, where they generally wane. The general character and formation of hurricanes is very much the same as that of the ordinary cyclones.

Galveston, New Orleans, Mobile, Charleston, Savannah, and Key West are the cities that have suffered most from the furious winds of the hurricanes. Unlike the tornado the wind of the hurricane gradually increases in force and lasts from twelve to twenty-four hours.

At Cape Lookout, North Carolina, there is no telling what the record force of the wind might have been had not the anemometer blown away after registering 138 miles an hour, during the fearful hurricane that hit that part of the coast on August 17, 1879.

There are other records of very high winds reported, namely 112 miles per hour was registered on Pikes Peak, Col., in January, 1881. At Cape Mendocino, Cal., in January, 1886, a gale of 144 miles an hour was recorded and at that point the anemometer blew away. Many Weather Bureau stations along the Atlantic coast have reported wind forces of from 80 to 100 miles an hour during hurricanes and winter storms.

Some of the temperature extremes that have been recorded in this country and at other places all over the world are most remarkable and surprising. At Ouargla, Algeria, on August 27, 1884, a temperature of 127.4 degrees Fahrenheit was registered in the shade. This is the highest temperature ever recorded. The lowest temperature ever known occurred at Werchogonisk, Siberia, on January 15, 1885, when the extremely low mark of 90.0 degrees below zero was attained. Other remarkably low temperatures recorded in Siberia are 80.5 degrees below at a place called Brascht, and 78.8 below at Merchmskoe. These towns, with such jaw-breaking names, are in a region where it is almost always perfectly calm, and that very fortunate fact helps to make the intense cold more bearable.

The ordinary mercury thermometer is of no use in recording extremely low temperatures, as mercury freezes at 37.39 degrees below zero fahrenheit. An alcohol tube is generally used in cold climates.

The lowest temperature ever recorded in the United States was at Poplar River, Montana, on January 1, 1885, where the low mark of 63.1 degrees below zero was reached. More recently, lumbermen and cattlemen of the Northwest have reported lower temperatures than that, but they cannot be relied upon as the thermometers used may not have been tested instruments.

Fort McDowell, Arizona, has the record for greatest heat in this country. At that place, in June, 1883, a temperature of 119 degrees was registered. Yuma, Arizona, is one of the hottest places on

(*Continued on page 190*)

### Is the Gasoline All Gasoline?

THE gasoline you use may contain impurities—possibly not, but the element of chance is never entirely removed. Not so with Uncle Sam who details the Petroleum Division of the U. S. Bureau of Mines to test all the gasoline used by the Government. If the product is not up to a high standard of excellence it is forthwith discarded.

The photograph illustrates Henry B. Cooke of the Bureau of Mines testing gasoline for the Post Office Department—hardly a retarding factor in the uncertain delivery of your mail! The apparatus, designed for this specific object, consists of a flask, electric heater, condenser, and accessories. A carbon residue instrument determines the quantity of carbon which remains after the oil is distilled to dryness. Another unit of the apparatus tells the time necessary for a certain volume of oil to flow through a specified capillary tube at a definite temperature.

The gasoline used by the Government—for example, the product employed in running the parcel-post motor trucks of the Post Office Department—is tested for the temperature of the initial boiling point and the final boiling or dry point. The results are compared with the figures specified by the Committee on Standardization of Petroleum Specifications, adopted for motor gasoline on November 25, 1919. If the fluid shows distillation temperatures above the standard temperatures at any point it is promptly rejected.

The instrument shown in the extreme right of the photograph is a closed-cup flash tester for determining the purity of kerosene and other oils. The U. S. Bureau of Mines will in the near future publish a bulletin describing the specially-designed instruments of Uncle Sam for revealing the quality of gasoline and oils used in the business of running the Government.—By *S. R. Winters.*

### Special Library Census

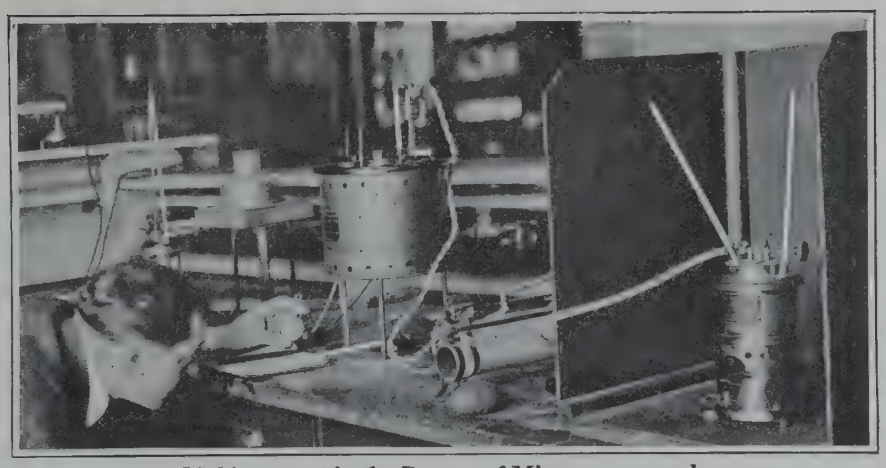
AT a time when the Government is counting up its inhabitants the Special Libraries Association is enumerating the special library collections of the country, because there does not exist at present an adequate directory of special libraries.

During the world war, when army camps and military centers were furnished with libraries for research and educational work, the men detailed to look up information for the Government were hampered by the lack of a satisfactory list of information centers which they might call upon for emergency assistance. Time and again army men could have used a directory of institutions or corporations having special information which they would permit them to consult, had such a publication been in existence.

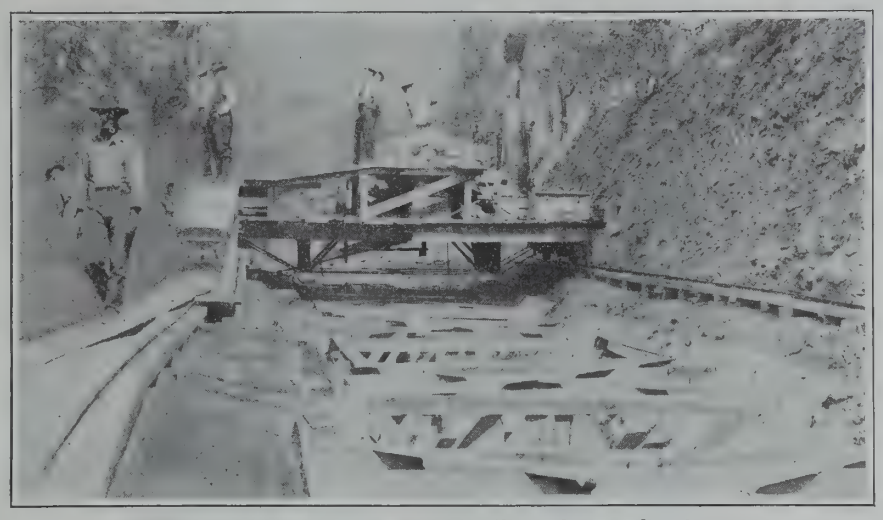
The business man realizes what it means not to have a directory of manufacturers at a time when he wishes to purchase a particular machine—and has no other way to go about it. His librarian is in just such a position when he or she is investigating a particular subject. Would it not be simpler if he or she knew of another library that had specialized on subjects of that type, and which had probably gone over the same ground?

When compiled, the directory will not be used as a mailing list for advertisers, but merely for the purpose stated, viz., to have in a central place a record of the special information sources of the country. A special library has been defined as:

"A good working collection of information either upon a specific subject or field of activity; it may consist of general or even limited material serving the interests of a special clientele; and preferably in charge of a specialist trained in the use and application of the particular material."

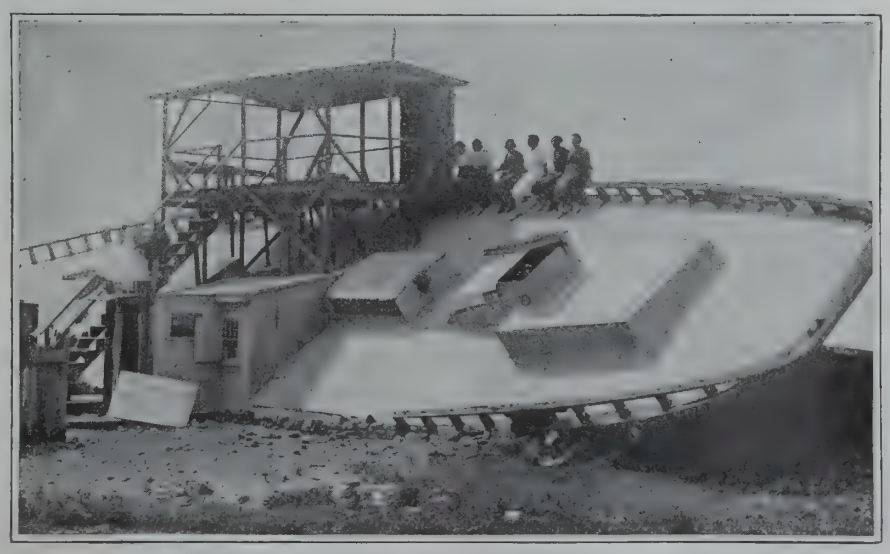


**Making a test in the Bureau of Mines on a sample of gasoline**



**This concrete plant travels on rails to the wooden forms**

**Fire resistive construction in a cotton warehouse, as it appears after a serious and widespread fire**



**This shipwreck has been converted into a summer camp with a seaside atmosphere**

If your library comes within the above qualications the S. L. A., will appreciate the following information from you:

Name of institution or company; name by which library is known; name of librarian or custodian; can it be classified as financial, business, legal, engineering, technical, institutional, municipal, reference, or agricultural; if it falls under none of these heads, the classification which you would apply to it; whether or not it serves a special clientele; would your librarian be willing to assist other special libraries to a reasonable extent?

The above data should be sent to Mr. William F. Jacob, Chairman Library Census Committee, General Electric Co., Schenectady, N. Y., who will be glad to answer any questions relating thereto.

### Wheeling the Concrete Plant to the Work

THE accompanying photograph shows a novel method employed in placing concrete lining for a canal. A track was built on either side of the ditch, and on this there was run a platform supported on four flanged wheels. On this platform there was mounted a donkey engine, and the concrete mixer. Portable inclines enabled the workmen to wheel the cement and crushed rock and sand on to the platform. When the concrete was properly mixed it was run through a wooden spout into the forms directly under the platform.—By *C. W. Geiger.*

### Saving the Warehouse When the Cotton Burns

FIRE resistive construction as applied to cotton warehouses has been developed to a high stage of perfection, to the extent that recently several of these buildings have withstood unusually severe fires which completely destroyed their contents without undermining or critically damaging the skeletons of the buildings themselves.

The initial cost of the reinforced concrete and steel system of construction followed in the building of fire-resistive cotton warehouses is high, but measured in terms of long-time wearability these storehouses are most durable and permanent. They are designed to favor the use of the most modern fire protective equipment and at the same time to withstand an intense and sustained fire. The accompanying photograph shows vividly how these buildings are able to resist the ravages of water and fire. Despite the fact that the entire stock of cotton was destroyed by a destructive conflagration, due to the excellence of construction and the permanency of the materials, the skeleton of the building is practically uninjured, the supporting columns, the walls, the floors and the roof, all weathering the extremes of heat, flame, smoke and water without seriously suffering from these damages or depreciation.—By *G. H. Dacy.*

### Putting the Wrecked Boat to Useful Work

AGAIN we reiterate the fact that in these days of housing shortage nothing in the way of shelter is permitted to go to waste. We add to our already large collection of makeshift houses the accompanying view of a wrecked ship—the pilot boat "Columbia," which was wrecked at Scituate, Mass., during the great storm of 1898. Some ingenious person saw an opportunity of converting that hulk into a museum and charging admission. At first the museum, containing relics of the sea and illustrating the story of "David Copperfield," was operated in this ship, but later the hull was used by a group of Boston girls as a summer camping spot. The hull is wired up with electric lights and is provided with windows and hatches for light and air.

# The Romance of Invention—XVI

## Charles G. Curtis—The Man Who Patented Efficiency In Steam Turbines

By C. H. Claudy

IT was years after the invention of the first steam engine before the idea was made practical for power purposes—literally hundreds of years. Hero, of Alexandria, is supposed to have been the first to make manifest the power of steam, his aeropile (a revolving boiler which obtained its revolutions by the impinging of jets of steam on the atmosphere) being at once the first steam prime mover and the first foreshadowing of the steam turbine of the nineteenth century.

Then, centuries later, came the steam cylinder, and for another two hundred years mankind forgot any other method of getting mechanical movement from the expansion of heated vapor of water. But there has always been the consciousness of a great waste and inefficiency in the reciprocating engine, and not all the efforts of all the inventors who compounded and duplexed, and who invented new and peculiar valve mechanisms, and more efficient boilers could get the piston and cylinder away from wastefulness.

Finally, inventors turned their attention to what is, perhaps, the oldest of all prime movers in the world—the water wheel, and considered if a steam prime mover might be made to work on the same principle. Came the first turbines, revolutionary in every sense, and a sharp division of this invention into two divisions—the De Laval type and the Parsons type.

De Laval evidently derived his idea from the undershot water wheel—that is, that the kinetic energy in the moving steam be made to give up its force by impinging upon the blades or projections of the rotor. In practice, a De Laval turbine makes a compromise between the ideal of turbine efficiency in this type—which would be reached if the speed of the blades or buckets could equal or nearly equal one-half the speed of the steam stream—and the limits of the strength of material, which forbids any such peripheral speeds as thousands of feet per second. In the De Laval type of turbine the steam expands at one jump from the full pressure of the supply to the pressure of the exhaust—it does this by being carried through a particular form of nozzle at the end of which the steam impinges on buckets in the rim of the rotor. But because the steam velocity (four thousand feet or more per second) is much greater than the possible velocity of the wheel, much of the kinetic energy of the steam stream is lost.

Parsons argued that if the steam were allowed to expand in many stages, instead of in one, and if each stage took its proportion of energy from the steam stream, a great gain in efficiency would be made—and he proved it with the Parsons turbine. In his invention, the drop in pressure is divided into many stages, and the buckets of the single wheel multiplied into thousands. Parsons also employs stationary blades so curved that the steam, winding in and out between moving and stationary blades, is made to give up energy by both its direct action or impulse and its reaction. And for many years it was thought that the Parsons type of turbine would prove the ultimate steam prime mover.

But then came Curtis with an entirely new conception of steam prime movers. Curtis believed that the De Laval principle of impinging a jet of steam on the bucketed edge of a rotating disk or wheel was the right principle. "Why not," he argued "combine the Parsons idea of steam expansion by stages, with the De Laval idea of steam impingement and the extraction of force by allowing moving parti- of steam to drive against resistance on a rotor? t have not one, but two or three or any de- r of De Laval wheels, each with its nozzle d so connected and so proportioned of steam stream to rotor speed is made economical and at the same time the least possible amount of kinetic energy is lost in the process?"

It is one thing to conceive an idea, it is another to put it into execution. Experimenting with steam engines in general and steam turbines in particular is a very expensive matter. Curtis did not conceive his invention as a drive for sewing machines—he dreamed of great installations for ocean liners, of huge prime movers on land for the generation of electric power, of great turbines which would displace the large reciprocating engines as power plants in factories. To build such an engine, even of modest size, is an expensive matter. To build it experimentally and try and change and alter and rebuild is still more expensive.

However, Charles G. Curtis has methods of his own. He is a believer in efficiency and a lifelong student of getting it, whether the thing in which it is to be had is a turbine, an electric motor, a factory or the disposition of his time. At the time his invention began to take form in his mind he was associated with Crocker (later Professor at Columbia) in the C. and C. Electric Motor Co. And it is interesting to remember that it was this concern which was responsible for the fan motor. Every artificial breeze which cools the offices and homes of the world today had its beginning in this company, which conceived and carried out the design for a small, cheap, silent and efficient electric motor for fan purposes.

In an experimental plant in Brooklyn Mr. Curtis spent some sixty thousand dollars in experimenting with his form of turbine. To invent anything is not particularly difficult. If it has any features of novelty it is not hard to get patents upon it. But as many an inventor has found, conceiving an invention and having it patented is one thing; selling it, putting it on the market, making it pay a dividend is quite another. But Mr. Curtis had something which the world wanted, and there were men in industry big enough to see it. So the land rights to the new idea in turbines were sold to the General Electric Company, which spent over three million dollars in developing the turbine to the point where it became commercial, that is to say, where its practical working and commercial manufacture could make its principles available for the production of the maximum efficiency in steam prime movers.

*INVENTORS are forever asking questions, and then going to work answering them. In fact, it is this matter of questioning the efficiency and desirability of existing things that makes for inventions, discoveries, progress. "Why not," argued Charles G. Curtis, "combine the Parsons idea of steam expansion by stages, with the De Laval idea of steam impingement and the extraction of force by allowing moving particles of steam to drive against resistance on a rotor?" This and other questions arose in the mind of Curtis. And proceeding to answer his own questions, he evolved his form of turbine, the Curtis turbine, which as a producer of power has a place all its own. But why tell about it here, when Mr. Claudy has undertaken to tell the entire story in the accompanying instalment of The Romance of Invention series.*—THE EDITOR.

**Charles G. Curtis, the inventor of the Curtis steam turbine which is widely employed in electric power plants and in marine propulsion**

It is difficult to express engine efficiency in percentages. Roughly the fuel or heat efficiency of an ordinary steam engine is less than fifteen per cent. That is, of the actual energy in a pound of coal, only about fifteen per cent is delivered in the form of available mechanical power. The reason is largely found in the absorption of energy in raising water from ordinary temperatures to the boiling point. During the expansion into steam so much latent heat is absorbed by the water in the process of turning into steam. There are also, of course, heat losses, and losses due to our inability to use all the kinetic energy in the steam. Could we utilize all the energy and have our steam escape from the exhaust of the reciprocating engine at no pressure at all—or even at atmospherical pressure—we would greatly increase efficiency, but to do this requires cylinders of such size and weight as are prohibitive in price and in friction produced. Every steam engine is a compromise between the maximum, theoretical, energy available and that which can be extracted with the greatest economy of friction, weight and expense.

The steam turbine has a higher efficiency than the reciprocating engine, the Parsons type has a higher efficiency than the De Laval and the Curtis shows a greater efficiency than the Parsons. But the advantages of the Curtis type over the other types are not only in a gain in efficiency but a gain in simplicity of construction and a great gain in practicability of use. A single point will illustrate this advantageously.

In the Parsons type of turbine there are literally thousands and thousands of steam buckets, both stationary and rotating. The clearance between them and the cylindrical casing must be very very small—in some cases as small as three hundredths or 1/33 of an inch. Make the clearance greater and there is leakage between the blade ends and the casing and an immediate drop in the efficiency of the extraction of power from the steam, for steam under pressure takes the easiest path and if it can escape *by* the blades, instead of weaving its way *through* them, it will do so, and expand without doing any mechanical work.

Now a clearance of three hundredths of an inch is a very small amount in a large turbine and the rotor and the casing must be most accurately made and again most accurately centered the one with the other, to permit the two to function with such a clearance. Consider, too, that expansion under heat must be taken care of, and that letting steam into a cold turbine too rapidly will expand the blades so that one or more may touch. This sounds innocent enough but actually it means wrecking the turbine, since the delicate blades, moving at high speed, need only a slight touch to bend over or break off, literally to churn themselves into small pieces.

In the Curtis type of turbine, where the steam is

(*Continued on page 191*)

## Soap from Clay—A Promise of British Chemists

SOAP from clay is the promise made by a group of British chemists who have been working on the utilization of this plentiful material for a number of years and who have just established the commercial usefulness of their discoveries. Their work is being described in a series of articles in a technical paper by Prof. F. C. Weston, a leading British authority on colloidal chemistry who has been in touch with their experiments.

Stripped of all technical verbiage what this group has discovered is a method of making use of China clay which is found in large quantities both in Britain and the United States, not as an adulterant, but as an ingredient in soap making. Soap, as most people know, is made now from fat and fat is scarce and expensive and is becoming scarcer and more expensive every year. China clay is plentiful and cheap. It can be had for the digging and the process of turning it into soap-making material is cheap and easy. It is claimed that it can be used up to fifty per cent in combination with the usual fatty acids in soap making and that the soap thus made lathers as well, is as cleansing and as pleasant to use as soap made in the old way of all fat. What this means to industry may be realized when it is stated that fats for soap making cost at present in England something like $200 a ton while the refined china clay can be produced and sold at an excellent profit for something like $75 a ton.

So far, the clays used have been from the famous Cornish beds but experiments with Georgia clays have demonstrated that they can be used equally well and no doubt there are many other clays in the United States that are equally suitable.

The process by which the clay is prepared is simplicity itself. After mining it is purified by a combined washing and chemical process and the resultant finely divided clay after being run into a settling tank is dried and is ready for use. It is a soft soapy substance without a trace of grit.

The purified clay has also been used in England in the manufacture of printing inks, for color striking, and a substitute for much more expensive chemicals in the vulcanization of rubber.

## Porcelain That Can Be Worked Like Glass

IT is well known both to the physicist and to the manufacturer that glass and porcelain behave very differently upon heating. While vessels of porcelain easily crack and burst and in consequence of this are not capable of taking a secondary alteration of form, most varieties of glass can be softened by heat and then bent, extended, or blown into the form desired. It is this quality of glass which is so useful to chemists and physicists in the laboratory and this is why glass is so greatly preferred to ordinary porcelain for the making of chemical and physical apparatus.

We learn from *Die Naturwissenschaften* (Berlin) that a Bavarian firm has lately succeeded in producing porcelain vessels which are highly resistant to changes of temperature. For the solution of this problem it was necesary to produce a glaze having exactly the same co-efficient of expansion as the mass of porcelain itself. In this way it was possible to obtain porcelain vessels highly resistant both to temperature and to fracture since the cracking and bursting of porcelain apparatus at abrupt changes of temperature is usually due to the creation of strains between the glaze and the mass as a result of unequal co-efficients of expansion of the two materials. These new porcelain vessels, on the contrary, can even have holes fused in their walls by an oxyhydrogen blow pipe without cracking. Moreover separate pieces of porcelain can be fused together exactly like glass, so that a porcelain tube, for example, can be fused into the wall of a dish. Finally this new porcelain can be softened and blown like glass. These qualities seem to assure it a wide usefulness.

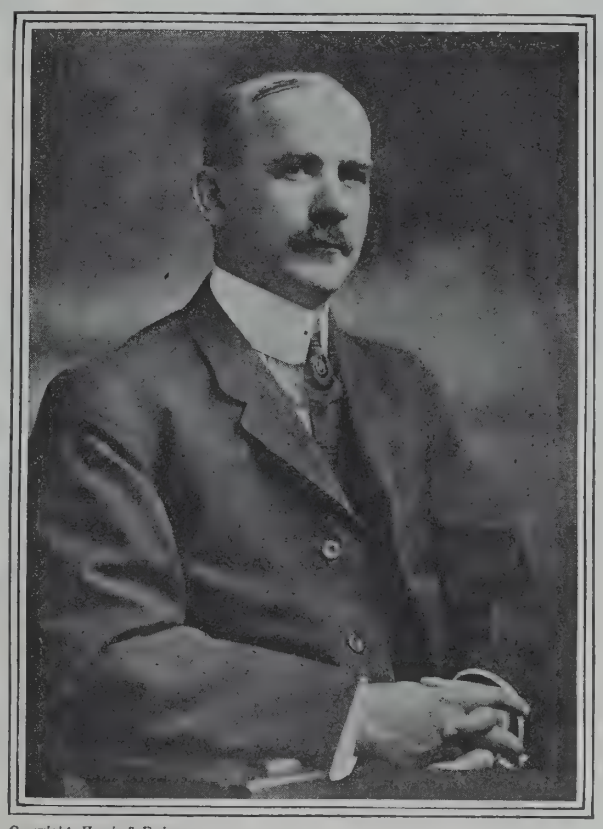
## Modern Version of the " Goose That Lays the Golden Egg"

A BRITISH paper prints the following interesting story regarding "Killing the Goose That Lays the Golden Egg." Nearly a hundred years ago Charles Lamb, in one of his whimsical essays, drew attention to the fact that many an old saw has in it a half-lie as well as a superficial truth. The idea that it is foolish to kill the goose that lays the golden eggs may in future be called in question as the result ot an experience which has befallen a farmer named Blackwood whose homestead is near Calgary. Blackwood killed one of his geese one day for dinner, and what should be in its gizzard but several gold nuggets. He proceeded to kill all his other geese, favorite and otherwise, and all the ducks, and the massacre yielded many additional nuggets. Naturally the discovery of gold-mining ducks and geese has led to a great rush of buyers of these birds. Thousands that have been roaming in the country adjacent to Blackwood's farm have been sold above par and are now "gone-west." Goose, with sage and onions, and roast duck are at a discount at the Calgary hotels, and a big rush of gold hunters or duck hunters is expected as soon as the new crop of ducks has a chance to feed up. Blackwood then scraped up a couple of shovels of black sand from his farm and took it to an analyst, who reported the sand to assay 18.30 grains of gold to the cubic yard.

## The New Commissioner of Patents

FURTHER evidence, if any were needed, that the Government is not competing successfully with large private and corporate interests for the services of the best men, is furnished by the resignation of James T. Newton, Commissioner of Patents, to take charge of the American business of a prominent British firm of patent solicitors. He is succeeded by Robert F. Whitehead, the thirty-third to hold this office since its creation.

Mr. Whitehead's home is in Lovingston, Nelson County, Virginia. He is a graduate of thē University of Virginia, and has had also a two years' course in



Copyright, Harris & Ewing

**The new Commissioner of Patents**
**Hon. Robert F. Whitehead**

mathematics and physics at Johns Hopkins, one of the cradles of American science. After teaching school for five years, he entered the patent office in February, 1902, at the bottom of the examiners' ranks. He advanced steadily through the various grades, finally being appointed law examiner. In May, 1914, he graduated into the distinctively executive class through his appointment as assistant commissioner, and in June, 1916, he received the rank of first assistant. He is a member of the bar in addition to the regular qualifications to be expected of a successful patent examiner, and has been admitted to practice before the District Courts and the Supreme Court of the United States. He was married in 1904.

Mr. Whitehead will take up the duties of the Commissionership immediately upon his return from a vacation in Maine. His record is such as to inspire every confidence in his ability to take up the administration of the patent office at the point where Mr. Newton has left it, and carry forward the excellent work of his predecessor.

## Alcohol Obtained from Coke-Oven Gases

WHILE in these prohibition days the possibility of obtaining alcohol from coke-oven gas in large quantities may not appear apropos nevertheless there is a practical phase which demands attention because of the prospect in relation to the motor fuel supply of the future. According to a paper read before the Cleveland (Ohio) Institution of Engineers the importance of this source of alcohol appears in the fact that one ton of coal yields 1.6 gallons of absolute alcohol. Thus the possible gain of alcohol from the coke-ovens of this country is 23.4 million gallons a year. If the gas-works were to recover their possible ethylene an additional 27,000,000 gallons would be available. This would leave the situation for motor-spirit as follows: Gas-works, 34,000,000 gallons of benzol and 27,000,000 gallons of alcohol; and coke-oven plants, 30,000,000 gallons of benzol, and 23.4 million gallons of alcohol; total, 114,400,000 gallons against 160,000,000 gallons required.

It was clear from the outset that whether charcoal or sulfuric acid was to be used in the purification, the recovery of ethylene and the manufacture of alcohol derivatives could not be made to pay unless the fuel expenditure was cut down to a minimum. This end is attained by utilizing waste heat. The point has been raised that with the removal of the ethylene from the coke-oven gas the calorific value of the gas will be seriously lessened. An investigation of the question has shown that when all is taken into account this loss of calorific power is negligible—only 1.1 per cent. Hence it is evident that the heating of the ovens will not be seriously affected. The processes described involve no new principle. The reactions are well known and therefore may be accepted without discussion. All that is claimed is the application of these reactions to industrial practice in the preparation of cheap alcohol from coal.

There are, however, certain new features in the carrying out of these processes, which features make for the success of the system.

## Effects of Manure Scarcity

ONE of the big subjects among Boston market gardeners nowadays is the question of location. Up to the advent of the motor truck, market gardens to supply the Boston demand were automatically kept close in, and as the available area of suitable land was limited it commanded a very high price, while its control placed the owning or renting gardener in a strategic selling situation. The motor truck tended to drive the market gardens farther out, and now there is another much talked of factor, the scarcity of stable manure.

The scarcity of stable manure, a consequence of automotive displacement of the horse, grows more and more serious. The heavy Boston supply, which formerly liberally supplied the market gardens, has fast diminished. Its further curtailment is anticipated. On any intensively cropped land, fertilization is a vital matter, and with stable manure supplies cut off, an immediate remedy is imperative.

It seems certain that entirely new fertilization methods will come into use. One method seriously considered at this time involves the use of gardens of larger size considerably farther out, trucks being relied on to get produce to market in time. Larger farms would enable the gardener to grow crops for green manuring, which, with the aid of artificial fertilizers, would meet the problem. The Rhode Island Experiment Station has conducted tests along this line which indicate it is practical, using green manures and chemicals, to dispense with stable manure in large part, or wholly.

This is a strong argument for the removed location, and there is just one serious objection to it. That is the labor question. Italian labor is mainly depended upon by Boston market gardeners. The laborers will work at a point reached by a short trolley ride, but refuse to go farther out. The consequence is that despite the stable manure shortage, recognized as permanent, Boston gardeners are still somewhat at sea over the question of location.

## New Application for Metal Spraying

THE metal-spraying process appears to have found a new application in engineering practice, according to an article in a German technical paper. It seems that the sand contained in the water jets supplying Pelton wheels may pass through the finest screens and still be sharp enough to destroy the buckets. Observation has revealed the fact that the sand-blast does not remove lead covering from iron, and it is therefore proposed that buckets for Pelton wheels should be lead covered by means of the so-called spraying pistol, in which a lead wire is fed automatically into an oxy-gas blowpipe and sprayed as a fine cloud of molten metal by the force of the gases. Lead applied in this way adheres very firmly to iron and steel as the minute particles are projected with great force and actual metallic contact is obtained, which is not the case when ordinary dipping processes are employed. Presumably the lead forms a sort of amorphous surface layer sufficiently elastic to counteract the erosive action of the sand particles.

# Announcing the PIERCE-ARROW Dual Valve trucks

In a full line including

a 2-ton truck
a 3½-ton truck
a 5-ton truck
and a tractor

with DOUBLE ignition and ELECTRIC lights.

They mark as notable an advance as the Worm Gear, introduced by Pierce-Arrow in 1910, which has become the dominant means of truck propulsion.

The adoption of the Dual Valve principle means greatly increased power and surprising operating economy.

THE GREAT EXPANSION of facilities and the efficient organization necessitated by War production developed invaluable experience enabling us to enhance the high quality which always has marked Pierce-Arrow.

THE PRESENT LINE *retains* these distinctive Pierce-Arrow characteristics—durability, long life, easy operation.

It *gains materially* in these vitally important attributes:

Pulling Power—equal to any demand

Gasoline Economy—more miles per gallon

Accessibility—for quick economical repairs

THESE ARE PRIMARY FACTORS in operation and maintenance—the true test of truck economy.

# Pierce Arrow

48 of the FIRST FIFTY trucks still running after 9 years' service.

Delivers more work in a given time.

Loses less time on the job and off the job.

Costs less to operate and less to maintain.

Lasts longer, depreciates less, commands a higher resale price.

THE PIERCE-ARROW MOTOR CAR COMPANY, BUFFALO, N. Y.

# The Motor-Driven Commercial Vehicle

Conducted by MAJOR VICTOR W. PAGÉ, M. S. A. E.

*This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The editor will endeavor to answer any question relating to mechanical features, operation and management of commercial motor vehicles*

**Special body adapted to the delivery of ice cream**

## Speedy Ice Cream Delivery

EVERYONE has observed trucks or wagons with loads of cracked ice and freezers of ice cream standing in front of a drug store or soda fountain and no doubt has noted the stream of water running over all under parts of the truck. This is particularly hard on the springs, frames and other smaller parts under the body.

An ice cream company of Milwaukee operates two two-ton trucks with bodies well adapted for this work. Three compartments, metal lined, are provided for ice or containers and another for salt. Partitions can be set in in order to facilitate the handling of brick ice-cream or regular freezers. Space is left in the center of the body which enables the driver to unload large containers with ease. Drain pipes lead from each compartment and these carry all water well below all the truck parts. A truck has just been purchased by another concern for this work, this one to have pneumatic tires for speedy delivery, which is shown in accompanying illustration. This also has a special body for carrying the ice and is fitted with drip pipes so the corrosive, salty water will not leak out of the body at points where it can collect on the machinery. The special body construction illustrated not only saves the truck mechanism from untimely depreciation but greatly facilitates the handling of the ice cream containers and the speedy delivery service is greatly appreciated by the trade.

## Repair Shop Trucks for Fleet Owners

MOVING repair shops, mounted on motor trucks, which were extensively used by the Government during the war to care for its large fleets of trucks at home and abroad, are destined to play an important part in facilitating the successful operation of the ever-increasing fleets of trucks operated by large companies, contractors and road builders throughout the country. With the increasing use of fleets of trucks in various lines of business, the machine shop truck, as a flexible medium for keeping fleets of trucks in constant running order, at a minimum loss of time, will become as necessary and vital a factor for commercial use as it was during the war.

The continuous operation of every truck is an important consideration with a fleet owner and in this respect the machine shop truck has proved itself a time and money saver through its ability to go direct to the crippled truck and put it in shape at a minimum of time. Mounted on the chassis is complete equipment to handle any kind of repair job. A separate motor furnishes the power for operating the various machine tools. This embraces such mechanical apparatus as a drill press, screw cutting lathe, electric grinder, blow torch, welding outfit, forge and more than 1,000 other pieces of machinery and tools.

Each tool and piece of machinery has its own location, insuring compactness when the end and side panels are up and the truck is in motion. The fact that a great number of these moving repair shops were furnished the Government during the war is proof of their value in caring for fleets of trucks. With the increasing tendency to operate fleets of trucks in various industries, the efficiency of the machine shop truck will soon make it an important factor with every fleet owner.

**A complete motion-picture equipment is carried in this large truck**

## Motorized Open Air Theatre

MOTION pictures on wheels is one of the latest developments designed by Messrs. De Pathy and Bergstrom of Hartford, Conn., the apparatus for which is shown in the accompanying photograph. In this motorized open-air theater bus are a motion picture machine, equipped with a 32-volt gas-filled lamp, a 1-kw., 40-volt, 1,700 r.p.m direct current generator and miscellaneous equipment. The generator is driven by a fabric band on the engine flywheel. The pictures are projected through an opening in the rear of the bus on a screen 40 or 50 feet distant, which may be stretched on any convenient building or between posts and trees. The owners intend to visit small towns and villages which do not support moving picture theaters, yet which have sufficient population to support an occasional performance. The expenses of operation will be materially reduced over that of running even a small theater and a regular route can be established so the latest thrillers will be brought to an amusement-loving public who would otherwise be deprived of this popular means of recreation. The truck is decorated in bright colors and serves to advertise the enterprise.

## Motor-Driven Wagon Loader

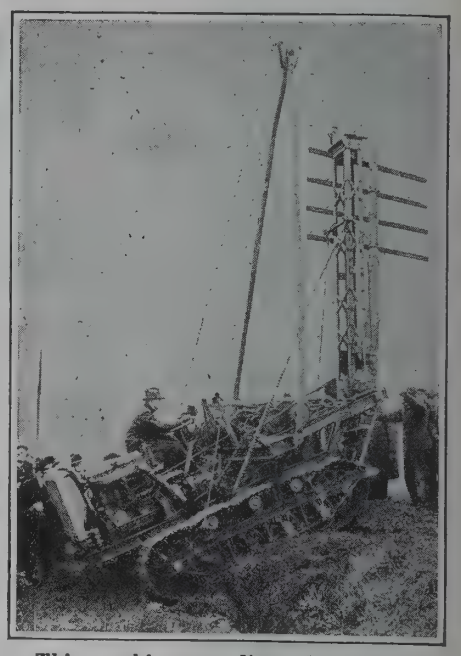
THE accompanying illustration shows a useful piece of machinery for coal dealers, contractors and others who use motor trucks for hauling such materials as sand, loam, crushed stone, coal, etc., which must be loaded from piles on the ground to trucks. The machine is a bucket type conveyor, the chain of buckets being driven by mechanism mounted on the loader chassis. Either an electric motor or a small gasoline engine may be used as a source of power for the conveyor to suit individual requirements. The conveyor mechanism is arranged so it can be adjusted for materials of various kinds and for different sizes of piles. Gearing is provided so the conveyor can be fed into the pile by its own power. The wheeled truck makes it easily moved. Needless to say, a machine of this nature will replace a considerable number of men at a marked saving. This combination of two familiar elements—truck and conveyor—is plainly a very happy one, and one that adds much to the utility of each. The independent source of power for the conveyor is a particularly good feature, since it makes it unnecessary to connect and disconnect between truck engine and driving gear of the conveyor each time the truck is filled and replaced by another.

**The motor-driven loader saves much time in operating a motor-driven fleet**

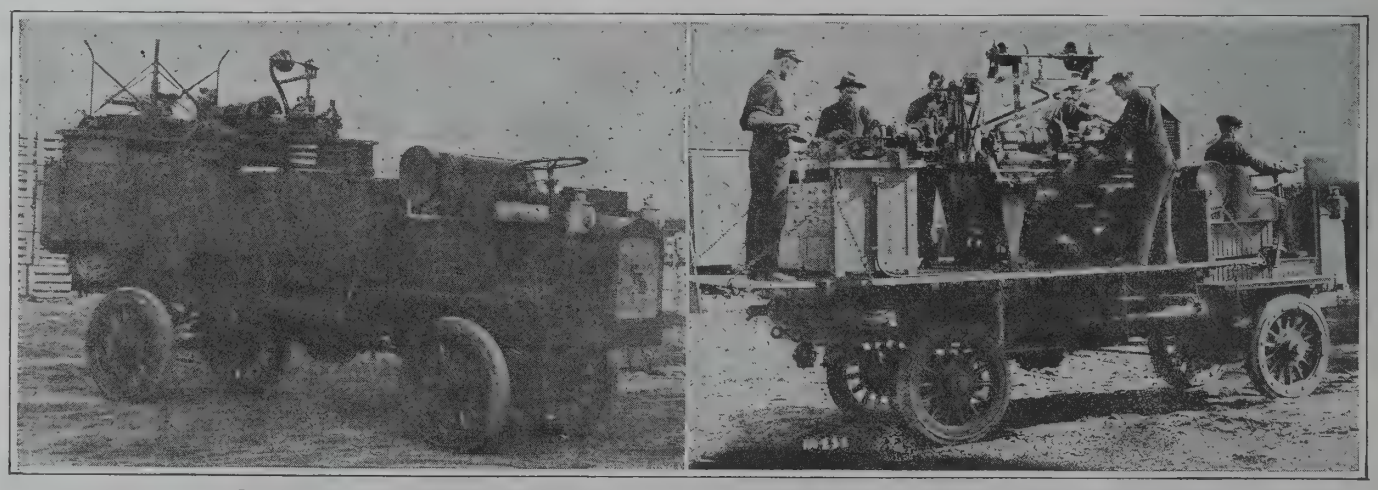
## Combined Tractor and Earth Boring Machine

THE accompanying illustration shows a field test on a recently devised traction engine which carries an earth boring machine used in drilling post holes. The machine proper consists of a structural iron frame carrying a shaft on which a large post hole auger is mounted. This can be fed down into the ground to make a hole of the required depth. This auger, which is carried on a vertical shaft is driven by chains and gears from the main power plant. The engine is the usual four-cylinder, overhead valve type that is very popular for tractor work and transmits its power to an auxiliary transmission controlled by clutch levers placed conveniently to the driver.

The entire mechanism is mounted on track laying traction members which not only makes it possible for the machine to maneuver exceptionally well on soft and rough ground but it also provides a large area of ground support for carrying the heavy propelling and earth boring mechanism. The frame carrying the auger can be set to drill holes at any desired angle when the machine is level, or to drill straight holes if the machine is tilted, which is inevitable if the machine is on a bank or high hill. The tractor not only carries arrangements for boring the post holes expeditiously but also has a triangular derrick boom so it can be used for setting the poles after the holes have been made for their reception. The value of a machine of this kind and its labor-saving possibilities can only be appreciated by contractors who have undertaken the task of setting out miles of pole lines by the usual methods.



**This machine expedites the work of boring post holes anywhere**



**The moving repair shop as it looks when on the go, and the same truck set up ready for work**

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farming Implements, Etc.*

## Of General Interest

FOLDING UNIVERSAL TABLE.—A. W. LEE, Rockwood Hale, Tarrytown, N. Y. Among the objects of the invention is to provide a folding table of light and simple construction and having its parts so positioned and arranged that the table, when not in use may be folded to occupy but little space and will have its various parts carried therein. The table is particularly intended for use in automobiles or vehicles and for campers, the legs are adjustable and all movable parts are held firmly in position.

MOP HEAD.—I. M. KAUFMAN, 601 Howard Ave., Brooklyn, N. Y. The object of the invention is to provide a simply constructed mop head in which the principal feature is the adaptability of the mop head to thick or thin mop cloths. The device comprises a frame, a cloth holding bar rotatably mounted to receive varying thicknesses of cloth, and means for clamping and holding the bar in position.

FOUNTAIN BRUSH.—W. GRACE, Hellabys Bldg., Queen St., Auckland, New Zealand. The invention is adapted to be embodied in brushes for various purposes, such as toothbrushes, shaving brushes, shoebrushes and the like. More particularly the invention relates to a fountain brush involving a reservoir or container adapted to receive a replaceable refil cartidge containing plastic or other material to be delivered to the bristles, feed means being provided to cause the paste or other material to be extruded as required.

SALVAGING APPARATUS.—C. SANGER, St. Louis, Miss. The invention relates to the salvaging of sunken vessels and the like. The prime object is to provide a tank capable of being submerged by filling the same with water which is subsequently discharged from the tank to render it buoyant. A further object is to so construct the tank that it contains suitable means for discharging the water and means for controlling the discharge.

APPARATUS FOR TEACHING ARITHMETIC.—R. A. JACKSON, Springfield, N. J. The object of the invention is to provide an apparatus for enabling teachers of arithmetic to readily test the scholars as to speed and accuracy in solving arithmetical problems. Another object is to provide a simple apparatus arranged to disclose a great range of arithmetical problems in addition, subtraction, multiplication and division, and to permit the teacher to quickly change from one branch to another and to vary the problems.

HOSE REEL.—G. L. PERRINE, Hillsboro, Ore. The invention has for its object to provie a device wherein the hose may be permanently connected with the source of water supply while on the reel, to permit as much of the hose as may be desired to be withdrawn from the reel for use without interfering in any way with the flow of the water. The reel might be used in connection with air hose as well as water hose.

YOKE OR SHOULDER WEIGHT CARRIER. R. P. ORR, 35 So. Manning Blvd., Albany, N. Y. This invention relates to weight supporting means for the shoulders of a person and has for an object the provision of a construction adapted to fit against the shoulders in such a manner that the weights connected therewith will be supported evenly over the entire shoulders, the arrangement being such that weights may be positioned so as to be supported by either shoulder or both shoulders simultaneously.

CARRIER RECEPTACLE.—R. P. ORR, 35 So. Manning Blvd., Albany, N. Y. The object of this invention is to provide a carrier receptacle with a number of compartments which may be easily supported while at the same time arranged to present easy access. Another object is to provide a carrier receptacle for mail carriers, soldiers, and other parties desiring an easy means for carrying one or more articles.

JUVENILE PRINTING BLOCK.—CAROLINE MONTEITH, 117 Scotland Road, So. Orange, N. J. The object of the invention is to provide a printing block for teaching children or beginners to read without the usual formal exercises by utilizing the natural activities and powers of children as they play and the art of printing their own reading material.

TAILORS' ORDER BLANK.—H. C. DIXON, Lodge No. 946, Protective Order of Elks, Tulsa, Okla. The invention has for its object to provide a blank of the character specified which, in addition to a complete record of the customer's measurements, will furnish one or more photographic views of the customer in order that the tailor may have before him a photograph showing the physical peculiarities of the customer.

ENVELOP.—W. HIRE, 297 Glendale Ave., Detroit, Mich. The object of the invention is to provide an envelop formed from a single piece of material so folded and secured as to provide a plurality of separate pockets, the specific arrangement of which is that they are adapted to contain different matter for mailing such as catalogues or circulars, it being possible to use circulars and catalogues of different sizes, which will reach their destination at the same time.

APPARATUS FOR EXTRACTING GREASE FROM ORGANIC MATTER.—K. A. STAHLGREN and T. L. SHANNON, address Thos. L. Shannon, 19th and Providence Ave., Chester, Pa. An object of the invention is to provide an apparatus for extracting grease from garbage and other organic matter in an exceedingly simple and economical manner. Another object is to provide a large heating surface for effectively heating the organic matter and at the same time insuring a thorough agitation of the matter and the solvent used to reduce the time of drying the organic matter and extracting the grease.

BELL RINGER.—L. LA MUNYON, Shoshone, Idaho. The invention relates more particularly to a construction and arrangement of striking device which may be utilized in connection with a bell, such as a fire alarm, an object being to provide a hammer which comprises a leaf spring and to which an oscillating movement is imparted causing a rapid and continuous vibration of the free end of the hammer.

FRUIT PITTER AND CUTTER.—W. N. RISDEN, Watsonville, Cal. An object of the invention is to provide a simple apparatus which will at a single revolution of the drive shaft operate to sever or cut the fruit in half and at the same time cleanly cut out the pit of the fruit. Another object is to provide a device which can be manufactured and sold at a reasonably low price.

FOLDING BOX.—P. A. HOFFMAN, c/o Smead Mfg. Co., Hastings, Minn. The invention relates to folding or knock-down boxes and more particularly to a folding box used for the mailing of currency and valuable securities, such as bonds, notes, mortgages, etc. The general object is to provide a folding box which can be variously folded to produce different capacities of receptacle whereby the box may be made to exactly and tightly fit its contents. A further important object is to provide for the proper sealing of the ends.

EYEGLASS CASE AND CLEANING DEVICE.—R. A. GOELKEL, 601 W. 137th St., New York, N. Y. The object of the invention is to provide a combined eyeglass case and cleaning device, whereby substantially any sized or shaped eyeglasses may have the lenses wiped while still in the case by a member having a rotary movement which is transmitted to the glasses so as to move the same over suitable wiping surfaces.

CAMERA.—K. CHEN, 75 Baikal Road, Shanghai, China. This invention relates more particularly to cameras of the reflex type, and has for its principal object to provide means whereby in case of necessity a wide angle lens may be employed. The invention aims to make the use of a wide angle lens possible by providing a slotted opening forward of the mirror to receive a ground glass in a frame for focusing, or in its place a conventional plate holder.

SWAGGER STICK.—E. L. YUNGK, 9 Elliott St., Hartford, Conn. An object of the invention is to provide a toy novelty which will be attractive in appearance and which will have an appealing influence upon holiday and festival occasions where celebration is engaged in by people of all classes. A further object is to provide a toy comprising what is known as the swagger stick and an audible tone-producing device and decorations.

HEEL.—A. H. SOMMERS, 225 Hamilton St., Allentown, Pa. This invention relates to fastening means for effectively securing the heel to the shoe. An important object is to provide a device of this character especially

MONEL alone is immune to the many destructive forces that shorten the life and so limit the service given by metals used for hundreds of purposes both industrial and domestic.

**Immune** to the corroding attacks of rust that eats away iron and steel.

**Immune** to alkalies and most acids that easily destroy copper, zinc or aluminum.

**Immune** to salt water that pits bronze and to superheated steam that quickly wears it away.

**Immune** to high heat that melts lead and seriously weakens most other commercial metals.

Strong as steel, more corrosion-resisting than copper, more wear-resisting than bronze, MONEL is a balanced natural alloy that combines the best physical properties of other metals without their limitations.

For obvious reasons MONEL is rapidly displacing other metals in many fields of activity. No other available metal or alloy possesses such a wide range of usefulness.

The name MONEL is given to a line of metal products produced by The International Nickel Company from a natural nickel alloy—67% nickel, 28% copper, and 5% other metals. These products include MONEL blocks, MONEL rods, MONEL castings, MONEL wire MONEL strip stock, MONEL sheets, etc.

# The Public Confidence

An important part of the management of the Bell System is to keep the public informed concerning all matters relating to the telephone.

We consider this an essential part of our stewardship in the operation of this public utility. It is due not only the 130,000 shareholders, but it is due the whole citizenship of the country.

We have told you of new inventions to improve service, of the growth of service, of problems involved in securing materials, employing and training workers, of financing new developments, and of rates necessary to maintain service.

You have been taken into our confidence as to what we are doing, how we do it, why we do it. You have been told of our efforts to meet unusual conditions; of how we have bent every energy to provide service in the face of storms, floods, fires.

It is an enormous task today to provide adequate service in the face of shortage of workers, raw materials, manufacturing production and transportation.

Nevertheless the service of the Bell System has been improved and extended this year. Over 350,000 new stations have been put into operation. And the loyal workers of the Bell System are establishing new records for efficiency and will establish new records for service.

Benjamin N. Bogue, 831 Bogue Building, Indianapolis

adapted for use with ladies' high-heel shoes and which will effectually secure the heel and prevent breaking away of the heel from the sole at the point of attachment or of the plies of the heel from each other adjacent to this point.

### Machines and Mechanical Devices

HYDRAULIC MOTOR FOR CHURN OPERATING DEVICES.—A. Roos, 1432 W. Monroe St., Chicago, Ill. An object of the invention is to provide a simple device by means of which water, as, for instance, that derived from a village water supply, may be utilized for operating the churn. A further object is to provide an adjustable device to meet the varying conditions of churns of different sizes or heights, and rooms of different sizes. The device is simple, having few parts, and therefore not liable easily to get out of order.

CAM AND PUSH ROD MACHINE.—J. Holle, 389 So. Belmont Ave., Newark, N. J. This invention relates to a cam and push rod mechanism for puppet valves and other devices and has for an object a device wherein a greater throw is provided by the same type of cam. Another object is the provision mechanism so arranged that the push rod will engage substantially flatwise against the face of the cam, and as the parts move the same will gradually move off the push rod on to the roller so that the push rod may return in easy manner over the rounded rear surface of the cam.

### Pertaining to Vehicles

VEHICLE SPRING SHACKLE.—J. J. Crawford, West New Brighton, S. I., N. Y. The object of the invention is to provide a spring shackle more especially designed to connect the eyes of a pair of semi-elliptical leaf-springs with each other and arranged to act as a shock absorber and to guard against breaking of the spring members. Another object is to absorb the minor vibrations and jolts incident to the vehicle running over rough roadways.

TRACTION WHEEL.—O. R. Hanson, Cadogan, Alberta, Canada. This invention relates more particularly to traction engines, whose wheels as now formed have broad flat treads, the object being the provision of simple means capable of ready adjustment to the wheels for the purpose of generally improving traction with either hard or soft ground, or traction surface which may be readily installed and which is capable at all times of efficient action and ready repair.

LOCK FOR TIRE CASINGS.—T. E. Cook and A. T. Freije, Rincon, N. M. This invention relates to locks for tire casings, and has for its object to provide mechanism to be used in connection with wheels having clencher rims for locking the shoe or casing to the rim in such manner that it cannot be removed by unauthorized parties. To prevent the removal of the casing a plate is provided which is shaped to fit upon the adjacent edges of the casing, within the same, to hold the edges of the casing from inward movement and thus prevent displacement.

VEHICLE.—L. Nussbaum, address Henry Shade, Quail and Elk Sts., Albany, N. Y. This invention has reference more particularly to an impellent ice or snow vehicle which includes runners with a frame made to accommodate an occupant who may thrust or push the same ahead by an impeller or the like. The primary object is to provide a simple, durable vehicle which may be manufactured at a low cost.

TEMPERATURE INDICATOR FOR AUTOMOBILE RADIATORS.—W. F. Jenkins, 1814 Hanover Ave., Richmond, Va. Among the objects of the invention is to provide an indicator which will exhibit a column of steam to the driver of the automobile immediately the radiator begins to boil, and to provide a radiator cap with means whereby the steam will be exhibited, so that the driver will be informed either in the day time or at night of the fact that the water is boiling.

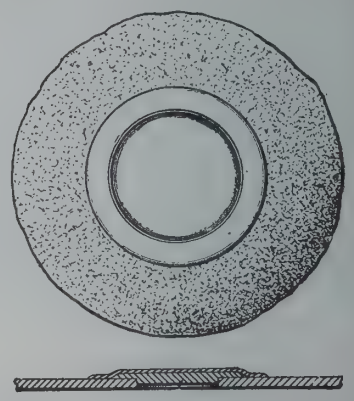
REBOUND CONTROLLER.—H. G Craig, R.F.D. No. 5, Washington Court House, Ohio. This invention has for its object to provide a device adapted to be arranged between the frame of a vehicle and the axle for controlling the rebound to prevent shock and jar, wherein the arrangement is such that the device offers no impediment to the compression of the spring, but cushions the expansion, and wherein the cushioning action may be varied.

TRACTOR WHEEL.—C. A. Slocum, 534 Milwaukee St., Denver, Col. The invention relates more particularly to a tractor wheel comprising a revoluble but rigid inner member surrounded by a revoluble but flexible outer member, the latter being so arranged that by distortion of its shape while in action it will spread out upon the ground and thus give a relatively large bearing surface, and consequently a better tractile effect.

TRAILER.—F. B. Allen, Joplin, Mo. The general object of the invention is to provide a trailer having a longitudinal bearing through which is disposed a guide pole adapted to be articulated to the rear of a truck, draft means being secured to the pivot of a bolster on the trailer and being adapted to be secured at the pivot to a bolster on the truck.

BICYCLE PUMP LOCK.—A. P. Lundin, 1491 *a* Xitchner Ave., Bey Valley, Johannesburg Transvaal, South Africa. A particular object of the invention is to provide a locking means permanently secured to one frame bar of the bicycle and positively locking the pump thereon to prevent unscrupulous removal. The device is so constructed that it will positively engage the pump and will automatically move out of engagement when the lock is opened by a key.

PROCESS OF VULCANIZING.—T. A. McAllister, 586 Broad St., Augusta, Ga. The invention relates to a process of vulcanizing, as for instance in the repair of pneumatic tubes and the like wherein it is impracticable



A TRANSVERSE SECTION AND PLAN VIEW, SHOWING THE PROCESS COMPLETE

or undesirable to place a backing of vulcanized rubber on the reverse of the tube to be repaired. The process consists in cementing to the outer face of the tire a sheet of vulcanized rubber and in placing raw rubber on the outer face of the sheet and vulcanizing the rubber.

EMERGENCY TIRE.—H. M. Shannon, Richmond, Tex. An object of the invention is to provide an emergency tire adapted to be quickly and easily applied to the automobile rim. Another object is to provide an emergency tire having high cushioning properties closely approximating the qualities of the pneumatic tire, the construction and arrangement being such that the device may be cheaply and easily manufactured while preserving strength and durability.

TRUCK.—J. T. Hall, 317 No. 11th St., Waco, Tex. This invention has for its object to provide a truck especially adapted for railroad use, as for instance, in handling baggage, freight or the like, wherein the supporting wheels are so arranged with respect to the body that they may be moved longitudinally thereof to permit the end of the truck to rest directly on the ground in loading, or to raise the body of the load well above the ground during transportation.

### Designs

DESIGN FOR A GEM SETTING.—W. Fischer, 67 Courtlandt St., New York, N. Y.

DESIGN FOR AN ARTICLE OF MANUFACTURE.—A. Flint, 267 5th Ave., New York, N. Y.

DESIGN FOR A PENNANT.—A. E. Langlois, 121 Hathaway Ave., New Bedford, Mass.

DESIGN FOR A BADGE.—D. E. Victor, 505 5th Ave., New York, N. Y.

DESIGN FOR A PURSE.—C. A. Nichthauser, 32 Union Sq., New York, N. Y.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

# Classified Advertisements

Advertising in this column is $1.00 a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

**AGENTS WANTED**

AGENTS—$40-$100 weekly; free samples, gold sign letters; anyone can put on store windows; liberal offer to general agents. Metallic Letter Co., 431X N. Clark Street, Chicago.

**BUSINESS OPPORTUNITY**

SUBSTANTIAL manufacturing corporation wants capable men to establish branch and manage salesmen. $300 to $2000 necessary. Will allow expenses to Baltimore as explained. Address, Mr. Clemmer, 603 N. Eutaw St., Baltimore, Md.

**HELP WANTED**

PATENT Office Draftsman. State experience and salary desired. Munn & Co., 233 Broadway, New York City.

**MANUFACTURING OPPORTUNITY**

A LABOR SAVING office appliance, having unlimited market, covered with basic (allowed) patent claims, with dies, patterns and parts ready for immediate quantity production (representing expenditure of about fifteen thousand dollars). Owner will consider offers for license, outright sale, or legitimate promotion. Address Office Appliance, Box 115, care SCIENTIFIC AMERICAN.

**"NATURE AND ITS EQUATIONS"**

"THE BASIC PRINCIPLE OF NATURE AND ITS EQUATIONS." Copyrighted. Price one dollar. Only through Gunnar C. Engstrand, 17 Battery Place, New York City.

**PATENTS FOR SALE**

FOR SALE Outright or on a Royalty Basis. Patent for a Lumber Loading device, also patent for a Wheeled Scoop for general use. The scoop may be raised and lowered to facilitate loading and unloading. Box 116, SCIENTIFIC AMERICAN.

**WANTED**

THE exclusive manufacturing rights of some machine, device, or article in the metal line patented or otherwise, by one of the most completely equipped manufacturing plants in Indiana. Address W. F. M.—P. O. Box No. 263, Bedford, Indiana.

# FORD CAR FOOT ACCELERATOR

Will sell patents, tools, dies, jigs, material for making, and 5,000 complete accelerators for Ford cars, because regular business requires all money and time. Accelerators tested by over a year's service; attach without alterations; works perfectly, increasing safety and reducing gasoline consumption; can be sold at popular price. Will assist in starting your production. Address Inventor, P. O. Box 647, Jamestown, N. Y.

## Is There a Coal Shortage?

*(Continued from page 174)*

All these things have heaped coals of fire upon the heads of the men who are responsible for the coal supply of New York's public utilities. Said one executive:

"I used to pay no attention to the coal problem excepting once a year when we renewed our contracts. Now I have to be constantly on the alert to prevent a shut-down of our system."

Realizing the delicate position of New York's public utilities with regard to a coal supply, and the terrific consequences of a shut-down, the Interstate Commerce Commission has granted priority to coal shipments to these concerns. For the present, at least, their coal problem seems solved and responsible executives say they have no fear of a coal famine next winter, unless some new circumstance intervenes.

All of this, however, takes no account of the industries which are served with coal that comes to or through New York. These present quite a different problem.

Few industries buy as much coal or as steady a supply as do the public utilities. As a result they find greater difficulty in buying coal at all and far greater difficulty in having it delivered. Such fuel is subject to seizure by the carriers and great quantities of it never reach their destination.

As a result, many of the industries have pooled their coaling facilities. Not only do they buy through a common agency, but they exchange coal among themselves by common agreement. Thus the manufacturer who has an excess of coal will come to the aid of the man who has none.

One such association, the Tidewater Coal Exchange, handles about 1,250,000 tons of coal monthly. The exchange was formed during the war to facilitate the handling of coal, as a patriotic measure, and has been continued as the beneficial results became apparent.

The Exchange classifies all coal coming to it and each classification is numbered, such as Pool No. 16 or No. 25. Members establish a credit by shipments to a certain pool or pools and they may then draw upon these pools for their supply. In special instances and in emergencies they may draw their coal from the pool before their shipment has actually arrived, or they may even draw out more coal than they have credit for. Credit in one pool may be transferred to another. The arrangement, on the whole, is a very flexible one and has practically eliminated the coal troubles of the firms who are members.

The greatest advantage of this arrangement, from the standpoint of the public, is that the movement of coal cars is greatly expedited. Cars do not have to stand on sidings until the consignee can unload them, but they are unloaded by exchange employees and the cars are immediately returned to the mines. A system of inspection and supervision is maintained by the exchange to protect the shipper and to speed delivery.

Officials of this institution say they are having no difficulty now in buying coal at the mines. As in the case of the public utilities, the principle difficulty is in transportation.

The general impression that a serious coal shortage exists or impends is no doubt fostered to a large extent by the abnormally high prices the householder and the small user of coal have to pay. The wide discrepancy that exists between the cost to very large consumers, and the cost to small users suggests that there is room for investigation. The basic costs are the same in each case. That is, the costs at the mine, haulage costs and insurance do not differ for coal users large and small, in the same locality. But the fourth item of expense—*profit*—may vary widely.

Since the large coal users are able to buy most advantageously and since they

# Whiten the teeth

## in this new way—remove the film

*All statements approved by high dental authorities*

**Millions of teeth are being cleaned in a new way. You see them everywhere — glistening teeth — teeth you envy, probably.**

**Now leading dentists join with us in urging that you try that method. Ten-day tests are being sent to anyone who asks. See how your teeth look after combating the film.**

### Film ruins teeth

**Dental science has discovered that film causes most tooth troubles.**

**Film is that viscous coat which you feel with your tongue. It clings to teeth, enters crevices and stays.**

**Much film escapes the tooth brush. The ordinary tooth paste cannot dissolve it. A soapy tooth paste makes it more viscous. So very few people escape tooth troubles despite the daily brushing.**

**It is the film-coat that discolors—not the teeth. Film is the basis of tartar. It holds food substance which ferments and forms acid. It holds the acid in contact with the teeth to cause decay.**

**Millions of germs breed in it. They, with tartar, are the chief cause of pyorrhea.**

### Now we combat it

**For years that film has been a vital problem. It is removed by dental cleaning, but in the months between it may do a ceaseless damage. And we have seen tooth troubles constantly increase.**

**Now science has discovered an efficient film combatant. Able authorities have proved it by many careful tests. Dentists have long employed it. And for home use it is now embodied in a dentrifrice called Pepsodent.**

## You can quickly know

**You can quickly see the Pepsodent effects. This ten-day test reveals them. And the book we send explains all the reasons for them.**

**The film is albuminous matter. So Pepsodent is based on pepsin, the digestant of albumin. Its object is to dissolve the film, then to day by day combat it.**

**This method long seemed impossible. Pepsin must be activated, and the usual agent is an acid harmful to the teeth. But science has discovered a harmless activating method. And now millions of people every day combat the film in this way.**

**Pepsodent combines three new methods to meet modern dental requirements. We urge you to try it. See what these new methods mean, both to you and yours. Cut out the coupon so you won't forget.**

**Pepsodent** PAT. OFF. REG. U. S.

***The new-day dentifrice***

***Now advised by leading dentists***

***Druggists everywhere are supplied with large tubes***

### Look in 10 days

**Send this coupon for a 10-day tube. Note how clean the teeth feel after using. Mark the absence of the viscous film. See how they whiten as the film coat disappears. It will be a revelation.**

# MONARCH LATHES

IN the great automobile factories, with production speeded up to the highest point to meet the ever increasing demand, Monarch Lathes are found delivering production finished with the minutest accuracy.

At the great small tool factories where every finished item must be machined to the closest limits, Monarch Lathes are found delivering a maximum production and long time service.

Where lathes are used, Monarch Lathes are found consistently backing up the guarantee of the maker, "Satisfaction to the user." And bearing this same guarantee there are more Monarch Lathes built and sold each year than are produced by any other manufacturer of high grade lathes.

**BESSEMER OIL ENGINES**

are supplied almost exclusively by the large mines, the profiteer, if he exists, is usually the small miner and his victim is the small user of coal.

Undoubtedly a factor in the price of coal is the large export demand. The mines of northern France once supplied a large part of her coal. These mines were flooded by the Germans and even so long after the armistice only one or two mines have been able to get into operation. The recent Allied demand indicates that the German mines are not being operated at capacity. England needs all of her coal and to meet reconstruction needs is importing more. As a result the United States is meeting an entirely new export demand. High prices can be obtained for this coal. It is said that in Paris coal is selling as high as $100 a ton.

Already there is a movement on foot to place a Governmental embargo on exportations. Undoubtedly such a step would improve domestic conditions, both as to supply and price of coal.

It has also been charged that coal cars which were diverted from their usual routes last winter to meet unusual conditions have never been returned and are being used to haul other materials.

On the whole there appears to exist a tension in the coal industry, based on the fear that "something is going to happen," rather than anxiety over present conditions. But it is almost the universal opinion of New York coal buyers that there will be no coal famine next winter unless some link of the chain breaks under the strain.

## An Engineering Bulwark

(*Continued from page 176*)

pated; such a budget will eventually effect economies in governmental activities that will be reflected in decreased taxation in which each citizen is vitally interested.

The creation of The Federated American Engineering Societies and its governing board, the American Engineering Council, is a matter of public interest, in that a trained body of several hundred thousand men will be available for the service of the public in those questions which affect the economic position of this country in the world as regards the economic administration not only of the government but of the state and of the community.

As an example of the service such an organization can render it may be stated that at the conference between the members of Engineering Council and Vice-President Marshall of the Senate and Speaker Gillette of the House of Representatives, Engineering Council proffered its services on matters upon which engineering advice of a disinterested character might be helpful, and Vice-President Marshall, in accepting, stated that this unusual and generous offer would be referred in writing to the Drafting Bureau, a new bureau of the Senate which has charge of the preparation of legislation.

The Federated American Engineering Societies will speak for a group of citizens which, by reason of special training and knowledge, represents a high order of intelligence and will provide a medium by which the talents that these citizens possess can be applied individually and collectively and unselfishly for the common weal.

## Record Weather

(*Continued from page 180*)

earth, and frequently reports temperatures near the 110 degree mark.

A couple of hundred of miles or so northwest of Calcutta, India, is a place called Cherra Punji, which is the very wettest spot in all the world. Here the annual rainfall averages about 38 feet—458 inches. The wet season there is during the summer months when nearly 300 inches of rain falls every year. The summer average is approximately three inches per day. During some of the particularly heavy cloudbursts they have in that region, there are records that show that as much as 30 inches of water have fallen from the clouds in 24 hours. June 14, 1876, holds the record for wetness, for on that day just 41 inches of precipitation was recorded. The year 1861 was the wettest year on record in that locality—900 inches of rain fell during the twelve months beginning with January, 1861.

Just as a matter of comparison it might be well to state that the average annual rainfall of our own metropolis of New York City, which we consider sufficient for all good purposes, is about 45 inches. There have been other remarkable rainfalls in this country and in other parts of the world.

At Vera Cruz, Mexico, nearly 200 inches of rain fell during a twelve months period a few years ago. At Neah Bay, Washington State, 140 inches of moisture fell from June, 1865, to June, 1866. At Upper Mattole, Cal., 41.63 inches was recorded during the month of January, 1888. At Alexandria, La., 21.4 inches fell on June 15, 1886.

A remarkable downpour of rain took place at Washington, D. C., on July 26, 1885, when .96 of an inch fell in the space of six minutes. This deluge descended from a heavy thunderstorm.

The extreme southern end of Florida and the southern California coast are the only sections of the United States where snow has never been known to fall. There have been slight flurries at various times in every other part of this country. At Punta Rassa, Florida, only a hundred miles north of Key West, snow fell for a few minutes on December 1, 1876. At San Diego, Cal., snow flurries occurred in January, 1882. But snow never lays on the ground south of the thirty-third parallel of latitude—which passes through the central portions of Georgia, Alabama, Mississippi, Texas and southern Arizona and New Mexico.

Heavy snowfalls have occurred in many parts of the Rocky Mountains—at Circo, in the mountains of northern California, 20 feet and 11 inches of snow fell during the month of March, 1882. In Wyoming and Idaho and Colorado there have been some remarkably heavy falls of snow during the winter and early spring months. It is not at all unusual for portions of those States to be buried under two or three feet of snow from a single storm lasting perhaps for a day or two. It takes several months of warm weather to melt the great masses of snow that cover the ground in some of these western and northwestern States.

Heavy falls of snow occur also in the Alps of Italy and Switzerland and other mountainous regions.

Summer snowfalls are unusual, and only a few have ever been officially recorded in the eastern part of the United States. In high altitudes and in the Far North they are not uncommon, but in this region they are.

At Colebrook, New Hampshire, in July, 1883, there was considerable of a snow flurry, lasting for five or ten minutes.

At Lynchburg, Virginia, there was a slight fall of snow on June 12, 1887. As recently as June, 1907, snow was reported to have fallen at Fredericksburg, Virginia—but there is no Weather Bureau observer at that place and no official report was made of this occurrence.

On July 12, 1888, it snowed quite heavily in the region of Mount Washington, N. H., and during the month of July of that same year snow fell in small quantities over parts of England and Scotland.

Weather records show many freaks and unusual meteorological conditions that have been recorded from various parts of the world that are most interesting and remarkable. Forecasting and studying the weather is most fascinating and absorbing, and scientists have made great progress along these lines during the past 30 years. That any degree close to perfection may be reached in making weather

GARCO ASBESTOS BRAKE LINING

forecasts is doubtful, for there are always certain elements and atmospheric conditions that may suddenly and unexpectedly arise that will change entirely the course of a storm or the movement of a cold wave. As an example that can be easily understood,—many storms form in the region of the Gulf of Mexico, and move northeastwardly to the south Atlantic coast, when they may continue in a northeast direction along the coast or they may pass out into the Atlantic Ocean, without causing any precipitation or winds along the coast. Sometimes, when conditions seem to favor the storm's passing out to sea, it will continue its northeastward movement and shoot up the coast—or vice versa, as the case may be. It is an even bet as to just what course these storms will take and it is doubtful if the weather experts will ever reach such a state of perfection that they can unfailingly predict which way these southern storms will move. However, there can be no doubt or question raised as to the splendid work performed by the Weather Bureau, and its value to the business and agricultural interests of this country.

### The Romance of Invention—XVI

(*Continued from page 182*)

allowed to rush from nozzles against buckets, the clearance may be amply sufficient to permit any degree of expansion of metal no matter how hurried—a quarter of an inch clearance is entirely practical. At one step, then, the Curtis type gets rid of many difficult details of construction. Again, in the Parsons type of turbine, what is known as a "dummy ring" must form a part of the turbine, this being a steam-tight joint between drum and casing, in which steam is kept from escaping along the shaft by a series of rings, each fitting in a slot of peculiar shape on the end of the shaft and requiring accurate end adjustment. There is no necessity for such a device upon the Curtis, because the steam does its work by expanding at the nozzle and the leakage of steam between the several chambers in which are the several rotating elements is not sufficient to make any material difference in the efficiency of the whole.

Control of speed in a turbine is as important as control of speed in any other form of steam engine. Here the Curtis is highly efficient, because speed is controlled, not by throttling down the amount of steam which enters the working chamber from the steam line, but by cutting off the supply of steam from one or two or more nozzles. Those nozzles which remain in action operate at full efficiency, but when two nozzles are presented with the problem of developing the work usually done with four nozzles, they accomplish of course, but half as much. Were the steam left in all four nozzles ("two" and "four" are used here diagrammatically, there may be many more in an actual turbine) but reduced in pressure by the throttle, none of them would work efficiently, and while speed would be reduced, cost of operation would not be reduced in proportion. The maximum Curtis turbine efficiency is found when the full force of the steam pressure is allowed to rush from nozzles against buckets. The maximum Parsons efficiency is found when the full force of the steam pressure enters the high pressure chamber. To reduce a Parsons turbine in speed, the pressure must be reduced. To reduce a Curtis turbine in speed the number of nozzles in use are reduced but the pressure in any nozzle remains the same.

It is difficult to say whether the Curtis turbine has been a greater success on land or at sea. Some five million Curtis turbine horse-power are in use in the British Navy, as much more in our own. Altogether there is over twenty million Curtis turbine horse-power in ships at sea or now building. The amount of Curtis turbine horse-power at work on land in the United States alone is over fifteen

AN inexperienced man needs good tools more than an expert does.

A good carpenter could get better results with a poor saw than the average householder, but *he* wouldn't use a poor saw. He would use a Disston.

When you do the little repair jobs around the house, you shouldn't cripple yourself by using a poor, blunt saw that sticks and binds in the softest wood and simply will not make a clean, true cut.

Get a Disston Saw! Note the keen, balanced blade of Disston-Made Steel, the well-set teeth that instantly bite into the hardest wood; get the "feel" of the handle that really fits the hand.

In doing your own work there's a lot of personal satisfaction that means more than the money saved.

Any work involving sawing is half done when you start with a Disston. The burden of the work falls on the saw, where it belongs, and not on the muscles of your arms and back.

Send for our booklet on the proper selection, care, and use of Disston Saws.

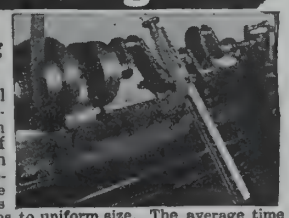
## Weber Crank-Pin Re-Turning Tool

**No Filing**
**No Offsetting**
**No Jigs**



This Weber Tool turns all pins absolutely round from one setting of Crank Shaft, on centers. A micrometer dial enables the operator to gauge his cuts and turn all pins to uniform size. The average time required for trueing up one pin is from 5 to 10 minutes. The 4 pins can easily be finished in 30 minutes, and the entire shaft is completed with only one setting.

**The Weber Tool is guaranteed** to turn crank-pins within as close limits of accuracy as any other known method. It will soon save its cost in any Tractor or Automobile Repair Shop. An assortment of cutting tools are furnished. These will fit the pins of most of the popular automobiles, trucks and tractors. Write for Circular and Prices.

# A NEW TRANSPORTATION ERA-
## BUT WHAT KIND OF PNEUMATIC TRUCK TIRES

NINE years ago, there were only about 25,000 motor trucks in the country. That was when *the first pneumatic truck tire ever built* came out of one of the U. S. Tire factories.

How changed today. More than 700,000 trucks. Over 5,000 truck *lines*, paralleling the service of the railroads. More starting daily.

The United States Rubber Company has long been preparing for this new transportation era. Looking ahead—realizing the part the *right kind of pneumatic truck tires* should play. Thinking of the *food* situation, the *industrial* situation—*every* phase of commercial transportation.

Its years of experience—longest of any truck tire manufacturer—have been devoted to this one objective: the construction of a *Truck* Pneumatic built for *Truck* service. With the result that it has been able to incorporate, in each U. S. Nobby Cord Pneumatic Truck Tire, a structural strength beyond anything ever attempted—as may be seen from the way its beads are *anchored*, its breaker strips *multiplied*, its flap *moulded*, its side cushions *bulwarked*, its holding to the road *made sure*.

* * *

The United States Rubber Company is providing truck owners *today* with the pneumatic truck tire performance they will be looking for when the *bulk* of the nation's freight business is being done by motor truck.

# Rainbow Sand Blast Hose

## Lasts Longer Than the Iron Nozzle

IN twenty-four hours a day service, under eighty pounds working pressure, Rainbow Sand Blast Hose showed a daily cost of fifteen and a fraction cents per length. Ordinary sand blast hose, at the same plant and under identical conditions, showed a daily cost of sixty-seven cents per length.

*Rainbow Sand Blast Hose* has repeatedly outworn heavy iron nozzles. Its special pure gum tube resists injury and abrasion from sand far better than any other tube.

A flexible four-ply body safeguards Rainbow Sand Blast Hose against sharp bends, kinks and the distortion of the tube—preventing severe wear at the bends.

The complete line of United States Hose includes a type and style of hose especially designed for every service.

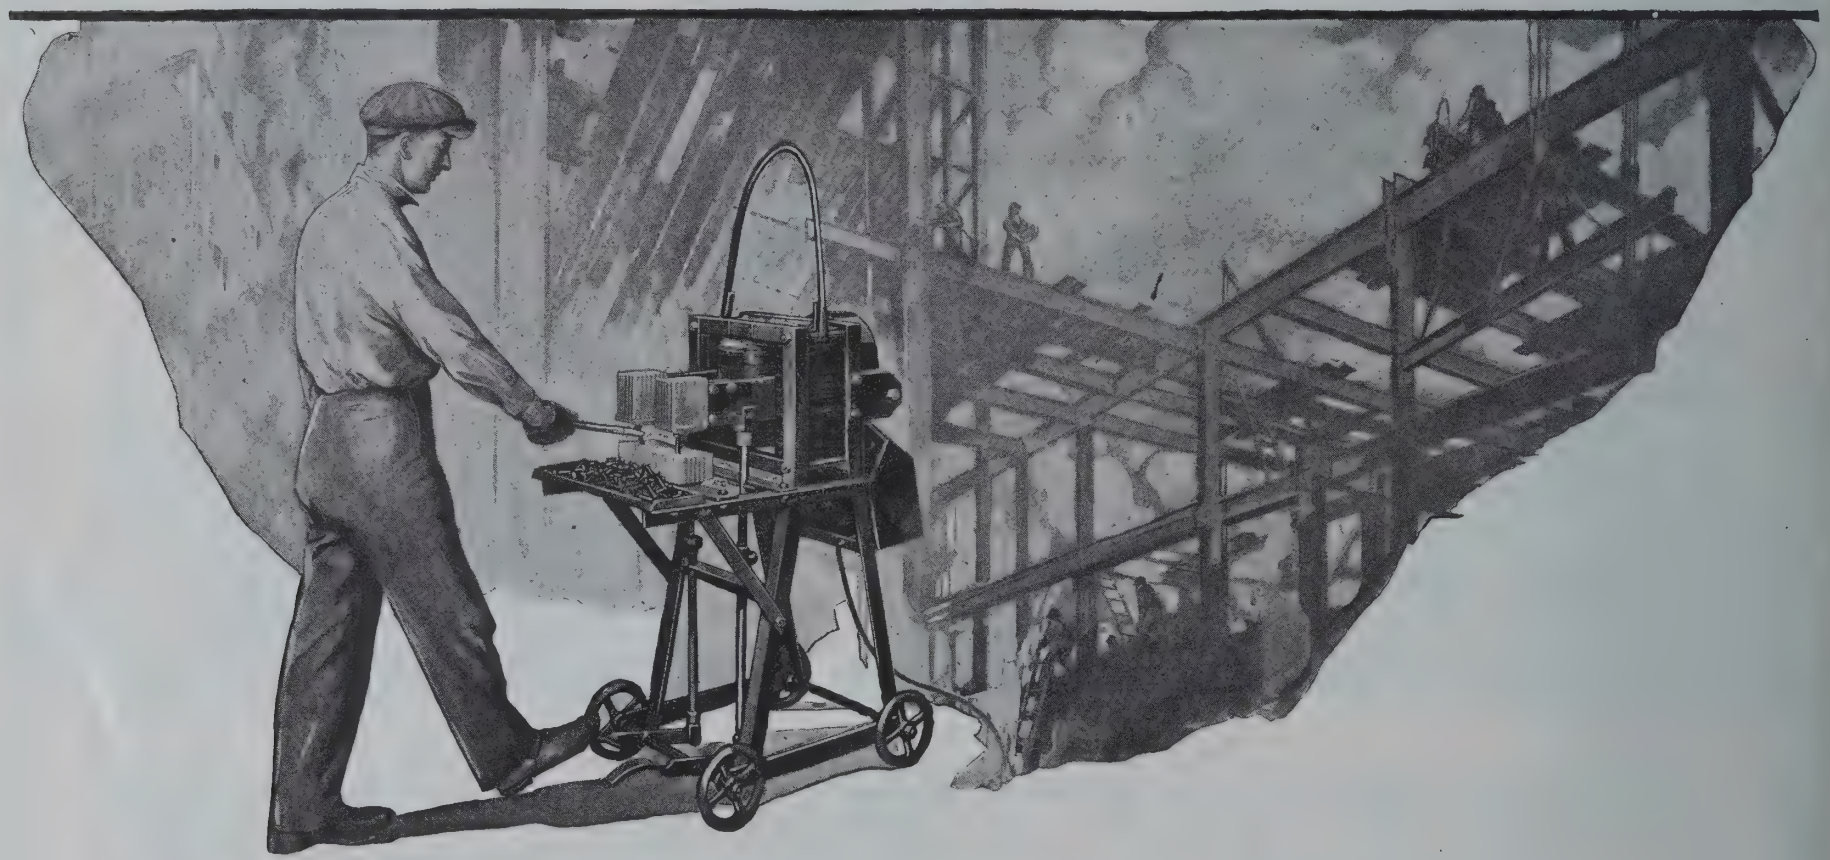
US RUBBER SYSTEM — UNITED STATES RUBBER COMPANY AND ASSOCIATED COMPANIES

THE SCIENTIFIC AMERICAN. August 28, 1920. Volume 123, Number 9. Published weekly by Scientific American Publishing Company at 233 Broadway, New York, N. Y. Subscription price, $5.00 per year.
Entered as second-class matter June 18, 1879, at the post office at New York, N. Y., under the act of March 3, 1879.

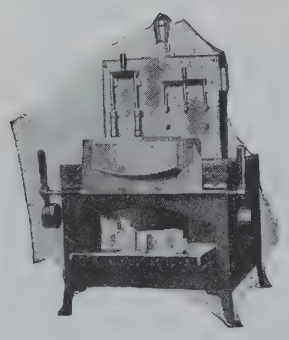
*Among the many benefits derived from forced production of war time, there is none more lasting or more promising than electric heat*



# 800 Red Hot Rivets per Hour

*Soldering iron muffle furnace*

*Electric soldering iron*



*Muffle type heat treating furnace*

WHILE the nation's shipbuilding program was in full swing, every day demanded rivets, more rivets and still more rivets. And the electric rivet heater helped shipbuilders to establish records that are now history.

This portable heater was carried to every corner of the ship, connected to a wire, and in a few seconds red hot rivets were supplied at a rate as high as 800 per hour, depending upon the size. No coal, no dirt, no cinders to bother with, no smoke and gas to irritate the workers — just a steady, uniform heat that works from the inside out, making the rivet shank hotter than the head, with the minimum of scale, fewer spoiled rivets and *current consumed only when rivets are in the jaws.* No wonder this ingenious device has won such wide-spread recognition in such a short time.

Performance of this kind is typical of the G-E electric heating equipment in a variety of industries. From the big electric ovens which bake the enamel on an automobile body with perfect results, down to the electric soldering iron which allows the man of the house to mend a leaky saucepan, the usefulness of electric heat is making itself felt in practically every place that heat is required.

The fact that electric heat is so simple to control, so accurate, so quick, and so safe under all conditions, makes it a vital necessity in some fields and a much desired improvement in others, regardless of its initial cost. This, together with the almost boundless resources of the General Electric Company in research as well as experience, insures the prospective user absolute reliability if he calls upon G-E to satisfy his heating requirements, large or small.

*Self-regulating solder pot*

*Compound melting pot*

**Details of the radio pilot cable which is to be laid along the route of New York's incoming and outgoing shipping**

## New York's Radio Pilot Cable

**By George Gaulois**

MUCH has been written about the electric cables used during the war for the purpose of piloting ships in and out of harbors at night. Indeed, it now appears as though this system of navigation is one of the greatest benefits derived from the war, and one that is just as important in peacetime as in war. However, with the installation of such a system in New York Harbor by the United States Navy, it is now possible to give exact details of how the radio pilot cable operates.

In brief, the principle of the radio pilot cable, as it is called, is to employ a cable through which flows alternating current. Ships intending to use the cable while passing in or out of waterways are provided with a pair of coils which intercept the electromagnetic waves emanating from the cable. By noting the relative strength of the waves reaching each coil, it is possible for the ship's navigator to determine when he is astride the cable. Once riding astride the cable, it is relatively easy to follow it along and thus steer a correct course. In certain installations two cables are laid, each carrying a current of a given frequency. Ship navigators can tell which is the incoming and which is the outgoing cable by making careful note of the sound of the waves. In this manner a route is provided for ships going in either direction, and the chances of collision are reduced to a minimum.

In the New York Harbor installation, which will follow the Ambrose Channel, one type of cable has been specified. This cable consists of seven strands of No. 16 tinned copper wire insulated with a layer of 30 per cent Para rubber 3/16-inch thick, over which is wrapped a layer of tape and jute, impregnated with a water-proof insulating compound. Over this layer of jute is an armor which consists of a wrapping of No. 12 galvanized steel wire. The overall diameter of this cable is approximately one inch. Some 87,000 feet of cable will be required.

There will be two anchors secured to the extreme end of the cable and only one anchor will be used at each of the three other points along the cable.

A one-killowatt motor-generator will be used for supplying 500-cycle alternating current to the cable. The voltage may be either 125 or 250 volts. Provision will have to be made for driving this generator from local source of current supply so as to maintain the motor-generator set at a constant speed. It is obvious that a fluctuation in the speed of the generator results in a change of note, which is apt to cause much confusion when using the cable. The amount of current flowing in the cable will be under control at all times and will range from one to eight amperes. A telegraph key is to be installed for the purpose of

## To Preserve a Beautiful and Historic Work

THREE-QUARTERS of a century ago a great American engineer, J. B. Jervis, built across the Harlem River, as part of the original Croton Water Supply, a handsome masonry aqueduct which stands today as one of the few remaining fine examples of the engineering work of its time. The High Bridge viaduct was built to carry the Croton aqueduct across the deep gap near the northern limits of the city through which flows the Harlem River. It consists of a series of round arches supported upon massive piers, two of which stand squarely in the navigable channel of the river. In that early day, the traffic through the Harlem River was light; but the river piers have come to form a very material obstruction—so great, indeed, that the United States War Department has demanded their removal.

With the construction of the new aqueduct which passes beneath the river by a large syphon, the old aqueduct has ceased to have any immediate use; and various plans have been suggested to deal with the resulting situation. The city's Department of Plant and Structures advocated the complete removal of the bridge; but the Department of Water Supply urged that the bridge be preserved as an emergency reserve.

Now the aqueduct is historically valuable as being a fine example of the early work of American engineers. John B. Jervis, who built it, was the chief engineer of the Croton aqueduct at that time and his claim to recognition and remembrance is enhanced by the fact that it is he who was the constructive engineer of two other great engineering projects, the Erie Canal and the Hudson River Railroad. Artistically considered, the Croton Aqueduct has always been regarded as one of the ornamental structures of magnitude in a city which possesses all too few works of this character.

We are glad to know that the American Institute of Consulting Engineers has taken this matter in hand and that they have drawn up a plan which aims to combine the new and the old parts of the structure in a way that will preserve the harmonious beauty of the whole. It contemplates the removal of two of the piers and the replacing of the three arches by a single arch of a flattened, semi-circular outline, with a clear height equal to that of the other round arches and a clear span of 231 feet. The interior of the structure will be built of reinforced concrete; its exterior will be clothed with the dressed stone removed from the old arches and piers which are to be replaced. As a consequence of this the face of the finished structure will match the rest of the bridge in the weather-stained appearance of its masonry and will harmonize perfectly with the tone and color of the whole bridge. Furthermore, an illustration of the reconstructed bridge shows that this central arch of wide span will relieve the monotony due to the constant repetition in the old bridge of arches of equal or approximately equal span, and that it will add greatly to the dignity and general architectural fitness of the whole work.

This meritorious suggestion should command the hearty approval not only of the authorities but of every citizen of greater New York. For not only will it preserve to the city a reserve aqueduct which, in case of emergency, might prove to be of greatest value, but the engineers have found that they can widen the top roadway and utilize it as an additional automobile driveway between Manhattan and the Borough of the Bronx, at a point where for over a mile there is no street connection between the two sides of the river. In its plea for the perpetuation of this structure by changes which will add to rather than detract from its beauty, the committee reminds us that the design of the aqueduct places it in the same class as the famous Roman aqueducts, the remains of which are among the chief attractions of the old world.

## "By Their Fruits Ye Shall Know Them"

WILL the day ever come when a discerning public will accord to the civil engineer the tribute of gratitude and perpetual remembrance which is surely his due when he conceives and puts through masterpieces of engineering construction? Is it not a reflection upon human nature that only in the rare cases when the engineer happens to be also the financier of a great undertaking, does posterity associate his name with his work? Too often the master mind which conceives a noble engineering project, solves its many problems as they develop, carries the burden of its multiplied anxieties, and transmutes his great dream into a splendid reality—too often he passes out of the public mind, and his name and fame are known only to the comparatively limited number who grace his own profession. Henceforth his masterpiece is associated with the name of the promoter and the financier, and to them accrue the rewards and financial profits.

A notable case in point is that of the distinguished engineer, J. B. Jervis, whose name, honored in the records of the civil engineering profession, is probably forgotten, if it were ever known, by the great world that for three-quarters of a century has enjoyed the benefits of his work. To think of the Erie Canal, of the Croton Water Supply, of the Hudson River Railroad, is to think of Governor Clinton and of that unique genius, Commodore Vanderbilt, not of Jervis. Mention of the Suez Canal brings to mind and always will De Lesseps; but De Lesseps was financier as well as engineer. The Panama Canal, to be sure, will be associated with the name of General Goethals, but he himself, doubtless, will tell you that, backed by the influence and wealth of the United States Government, he merely applied great organizing ability to the carrying out of a plan that was formulated and developed by men whose names have already, so far as the Canal is concerned, passed into obscurity. Foremost among great engineering works is our original New York subway system, the work of William Barclay Parsons; but, except for a commemorative plate in one of the least-used of the local stations, there is little to remind us how greatly we are indebted to this engineer for solving the problem of rapid transit at a time when the city was threatened with unparalleled congestion.

There are, of course, notable exceptions, prominent among which is the beautiful suspension bridge across the East River—to think of the Brooklyn Bridge is to think of Roebling. But among the millions who have crossed and will continue to cross the great Forth Bridge in Scotland, how many recall the fact that the construction of this majestic work was due to the fine vision and daring of Benjamin Baker. True it is that, following an admirable precedent, Baker was rewarded with a baronetcy, a practice which is common among the older civilizations. Our prejudices prohibit the granting of such rewards; but we cannot but feel that in some other way a means might be found to perpetuate in the minds of a so greatly enriched posterity the memory of the men who, in the routine of their honorable profession, have the imagination to conceive, the courage to suggest, and the ability to carry through works of the first magnitude.

## The Scope of Common Law Trade-Marks

THERE are two features of American trade-mark law which are not adequately understood by the majority of trade-mark users. One of these is that trade-marks are not property in the sense that we ordinarily give the term. The right to use a trade-mark is something that can be established in this country only by its exercise; the source of the trade-mark right lies ultimately in the use of the mark, and not at all in the official document that certifies this use to be a matter of public record.

The second point to which we would advert is that trade-marks are not under the entire control of the Federal Government. Acting under the provisions of the Federal Constitution which delegate to that Government exclusive control over all matters affecting foreign and interstate commerce, Congress has passed certain acts applying to trade-marks. But trade-marks are as old as the common law. Small manufacturers, who to all intents and purposes restrict their business to the State in which they are located, may adopt trade-marks, and having by using these marks established their right to use them, may through the State courts protect these rights in the State.

But there are in the English language a limited number of words. It is certain that cases will arise in which identical or similar marks will be originated and used independently by different persons. Usually these marks will be used on entirely different articles. But the long arm of coincidence knows no limits; small concerns doing similar local businesses in different parts of the country now and then hit upon the same word or other mark to identify their goods. This is all well enough so long as these businesses stay put in their original limits; but when one or both expand, there is the possibility of their coming in contact.

In practice this actually happens. John Jones, of some Connecticut town, the local apothecary and known to all his constituents by the affectionate diminutive, has a wonderful cure-all descended from his great-grandmother which he dispenses over his prescription counter. At length he puts it up in little packages and builds up a small business in the neighboring counties, having branded the article as Jack's Infallible Nostrum. The business eventually spills over the State line, and finally arrives in the northeastern corner of Ohio. There it strikes a snag.

It appears that some ten years after the mark Jack's was first applied to Mr. Jones medicament, or perhaps ten years before, a Cuyahoga County gentleman by the name of Jackson had invented a very successful cure for the distressing symptoms of the morning after. In recognition of the fact that his acquaintances found two syllables too much of a mouthful in pronouncing his name, he identified this to the local drug trade under the name of Dr. Jack's Miraculous Remedy; and it has had a considerable sale ever since.

It may seem that these are rather trivial and unsatisfactory grounds on which to base the selection of a trade-mark; but a vast majority of the marks in existence have their origin in some equally trivial fact or incident. As the case stands, there is no suggestion and no belief by either party that the other has consciously imitated his mark. Yet one or the other is sure to feel that his rights are invaded. Either the Jones remedy must be barred from Ohio, or the Jackson panacea must be subjected to competition in the established field of its sale by another article of a name similar enough to lead to confusion.

A case recently decided in the Supreme Court was along substantially these lines, the good faith of the two users of the same mark being mutually admitted. The Court laid down the principle that the date of original adoption by either party, and the particular territory in which they now meet, are of no moment. And it then enunciates the eminently sensible doctrine that if either of these "Jacks" had ever wished to protect his mark in interstate commerce, the Federal laws provided him with the opportunity to do so. That neither of them availed himself of this opportunity is evidence that each has been negligent in allowing certain inchoate rights to lapse. So the Connecticut Jack may sell under this mark in the territory where he was first established, and the Ohio Jack may do likewise. Each Jack retains all the rights in his mark which he has previously exercised and no more.

Every small business can profit by the tale thus anonymously and parabolically told. The very first sale in interstate commerce of any marked article can, and should, be made the ocasion of application for a Federal trade-mark. Then if there is any reason why such application cannot be granted this fact will become known in time to prevent the building up of any considerable business under a mark that is open to infringement; and if there is no such reason, permanent trade-mark protection is attained.

# Gas Engine Versus Steam Engine

## The Rôle Which the Motor Truck Can Play in Transportation, as Indicated by California's Experience

By H. A. Crafts

IS the gas engine destined to displace the locomotive? Is the auto-stage to take the place of the passenger coach? Is the auto-truck to supplant the freight car? These are questions that are agitating thinking minds.

These questions are of interest everywhere, but nowhere more so than in California, because California has so long been under the domination of the railroads. Nor is the subject merely speculative. The possible change seems to be on the way. And such inroads are the motor truck lines making upon the revenue of the railroads that the latter are up in arms about it.

One of the important civic institutions of California is the State Railroad Commission. This body has wide plenary power, and does things. It fixes rates to be charged by every common carrier whether it be a railroad or a line of motor trucks. It gives audience to all sides and carefully notes all important evidence. It has power to raise or lower tariffs, as its best judgment may dictate. One of its functions is to grant licenses and franchises for various kinds of transportation lines.

Just the other day the California State Railroad Commission was sitting in the city of Oakland. G. F. Nesson and A. C. Woodward had put in an application for a franchise for a motor truck line to run from Oakland to San Jose, fifty miles south. The railroad folks were there to oppose the granting of this franchise.

The feeling in railroad circles as to the motor truck lines was indicated by the strong language employed by Edward Entelman, assistant superintendent of the Railroad Administration, in his testimony before the board. He referred to the motor truck lines as "robbers of the highway," and charged that they were "not dependable." Then he went on to say:

"Profits that the Southern Pacific Railway Company are making on the line between Oakland and San Jose are very small. On the average the haul from San Jose amounts to only about three carloads per day."

Similar views were expressed by J. L. Allen, traveling agent for the American Railroad Express Company.

In rebuttal of this testimony W. J. Harris, wholesale produce merchant of Oakland, testified that the railroad service between Oakland and southern points was inadequate, particularly in the handling of perishable goods. Slowness of delivery on the part of the railroads was the chief complaint made by Harris. Produce from the South, he said, was not delivered early enough in the day to permit prompt distribution.

"If the produce is not at the store at 5 o'clock in the morning," said Mr. Harris, "the railroad may as well keep it until the next day. As a matter of fact the railroad company seldom makes deliveries before 8 o'clock in the morning." In consequence of this defective delivery on the part of the railroads, Mr. Harris further testified, the commission merchants of Oakland had been compelled to install their own truck lines. But it is not necessary to take the testimony of the railroad people nor of the motor truck men to get an idea of the expansion of the "ship-by-truck" business in California. That which we see every day on the city streets and country highways is sufficient to convince anyone of the revolution that is going on in transportation circles. The motor truck is in evidence everywhere.

From the country districts it is bringing in great loads of milk, butter, eggs, poultry, fruit, vegetables, hay, grain, and other farm products. Often the truck hauls a train of trailers, all heavily laden, yet whirling along the highway at a lively clip. The old-fashioned early milk train on many railroads has become almost obsolete, the big dairies having installed an efficient motor truck service on their own account. The poultry and egg people have followed suit, and with their trucks make four collections and as many deliveries in a day. Outward bound trucks laden with merchandise, household furniture, etc., are in equal evidence. Public motor-truck and auto-stage lines multiply daily and radiate from the larger centers in every direction.

In San Francisco there are 26 regularly organized motor-truck lines that run on regular schedule time. These lines cover routes all the way from five to two hundred miles in length, reaching such points as San Jose, Stockton and Sacramento. Oakland has a motor truck system of almost equal size. The auto-stage lines are also numerous, and their routes extend as far as Los Angeles.

These lines are establishing neat and comfortable passenger stations in the central part of the city. Their time-cards are all worked out to a nicety and occupy prominent places in public view. They appear to be doing a flourishing business, and are most attentive to the needs and comforts of their patrons.

The whole business presents an aspect of extreme democracy. A condition of cordial good fellowship seems to exist between agent and passenger, and between passengers themselves. The latter, in their departures, their arrivals, and their progress along the highway appear more like parties of joy riders than mere wayfarers. These lines make a point of having ample rolling stock and operatives on hand in order that all travel may be handled promptly, and on schedule time.

Both the auto-stage lines and the motor-truck lines appear to bringing the city people and the country people into closer relationship, socially as well as industrially. The two forces are not only revolutionizing established lines of communication, but are developing new fields, remote sections hitherto isolated from the world.

I have it upon the authority of leading automobile experts that there are today in California more than 900 towns and cities containing an aggregate population of 89,000, which are absolutely dependent upon highway transportation. These out-of-the-way places are being brought into closer touch with the centers of popula-

### Taking the Guess Out of Photography

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of March 13th last, in the page devoted to "Inventions New and Interesting," I notice under the above heading that a New York press photographer has invented a novel way of focussing hand cameras by means of a telescope, the objective of which is of the same focal length as the lens used in the camera. I am afraid this photographer must content himself with the credit due to a re-inventor, as the device is over thirty years old.

In the "Optics of Photography and Photographic Lenses," by Mr. J. Traill Taylor, published in 1892, a whole chapter is devoted to this very method. The author discusses the question fully, first mentioning a demonstration of the arrangement in 1886, and then dealing with the inadequacy of ground glass screens: aerial images; the nature of the focussing telescope and its adjustment to the camera; the use of the system, and the adjustment of dissimilar lenses to effect any requisite correction of the telescope objective in respect of focal length.

The book could probably be seen in any technical public library, and the chapter in question (No. 29) appears in page 170 of the edition of the work published in London in 1892. Mr. Taylor's name is of course well known as a writer on photographic matters and as a former editor of various photographic papers, including, at some period, the *Photographic Times* of New York. "T. H. P."

Toronto, Ont.

### Who Will Buy Dutch Factories?

To the Editor of the SCIENTIFIC AMERICAN:

At the moment there are for sale in Holland various works, factories and engines, whose present proprietors are without funds to continue their businesses. We are taking the liberty to bring this state of affairs to your attention, and hope that you may be able to give the matter publicity. We should think that American business men might profitably take advantage of the opportunity to buy these items, in view of the fact that the present exchange rates would enable them to buy at very favorable prices. In Germany, too, there would be wide opportunities of this sort, and here the difference in exchange would operate even more in your favor. We should be pleased to handle any inquiries covering this matter.

Arnhem, Netherlands. GEBR. OOSTERHUIS.

### First Naval Electric Drive

To the Editor of the SCIENTIFIC AMERICAN:

May I venture to correct your naval contributor in a statement which appears on page 712 of the June 26th issue just to hand. He states that the U. S. S. "Jupiter" is the first naval vessel of any nation to be fitted with electric drive. If you look up reliable books of reference you will find that the German submarine salvage ship "Vulkan" was the first (1907).

FRANK C. BOWDEN,

London, Eng. Captain, Royal Marines, Retd.

### Further Data on Mexican Oils

To the Editor of the SCIENTIFIC AMERICAN:

Your unexpectedly early publication of my article, "Our Future Oil Supply," forestalled me in certain corrections which have become in order since the original preparation of the manuscript, and which I had intended to ask you to make before you set this matter up. I should appreciate it if you would find space somewhere for them now.

American operations were carried on in the Mexican fields before the date, 1904, which I mentioned; but it was in that year that work was first attempted in earnest.

If I were writing today of the Juan Casiano well, I should have to employ the past tense and speak of its total output rather than its production to date. Just the other day this splendid producer suffered the fate which had already overtaken the Portrero del Llano, being drowned out by salt water.

In speaking of the third field of Mexican oil operations, that of the extreme south, I would like to make the point that in portions of this field, especially in Tabasco, shallow sands are encountered, principally at depths of 400, 800 and 1,200 feet, which are believed to have great possibilities and which have already shown excellent results. Oil seepages here have been known by the Indians for years and the fluid used for medicinal and other purposes.

A. HOOTON BLACKISTON.

### The Life Gun On the Ship

To the Editor of the SCIENTIFIC AMERICAN:

I was very much interested in the letter that appeared in your issue dated June 19th, written by Capt. Edward G. Bancord regarding line-throwing gun, and wish to add a correction and a suggestion.

The Captain quotes the Steamboat Inspection rules as they were. These rules were amended on February 21, 1919, to read:

"All steam vessels of 150 ton gross or over navigating the ocean shall be equipped with at least three line-carrying projectiles and means of propelling them, of a type and character which have been officially approved by the Board of Supervising Inspectors."

Being the inventor of the gun illustrated on cover of your issue of January 31, 1919, and having given this particular subject much of my time and attention for the past two years, I feel that I am qualified to speak on the subject, and note that the Captain speaks only of getting a connection between a ship that is stranded and the shore for the purpose of rigging up a breeches buoy. Will he not agree with me (and every seafaring man that I have spoken to on the subject) that its usefulness extends far beyond aiding stranded vessels, especially in getting a hawser to a ship at sea that has broken down and sent out a call for help?

For every case where a vessel goes on to the beach, there are fifty breakdowns at sea in which instance the vessel loses her steering way and is wallowing in most instances in the trough of a heavy sea, making it impossible for the rescue ship to approach too near on either the windward or the leeward side without assuming too great a risk. Right here is where the line-throwing gun can be used to advantage in getting a hawser to (or from) the crippled vessel with which to get her head to sea, or for towing her into port.

New York. MAX RINDSKOPF.

# A Neat Problem in Hydraulics

## How the Delaware River Was Held at Bay During the Construction of the Naval Drydock at Philadelphia

By J. F. Springer

IT is more or less notorious that engineering work involves unknown factors. On a big job it is frequently the case that no one knows what great problem lies ahead. Suddenly, the unforeseen or the unforeseeable happens. The thing that has taken place or the facts that have been discovered may affect the whole general plan and effect a revolution in the method of attack. Men are trying to eliminate uncertainties, trying to ascertain in advance precisely what conditions will have to be encountered at every stop. And a good deal of progress has been made along this line. It is now considered quite the thing to put down exploratory bore-holes over a site where some important work is to be located, the purpose being to find out precisely what the excavation and construction problems are going to be. A good deal of expense is thus incurred; but the money spent is well spent. But, do what he will, nature has so many and so various things at her disposal that she is still able to provide man with surprises.

The big dry dock now under construction for the United States Navy at the Philadelphia yard offers an illustration of the occurrence of the unexpected. A considerable number of bore-holes were put down. These revealed the character, thickness and relative position vertically of the strata covering the site. It was ascertained that a thick stratum of tough red clay covered the site at a level suited to provide a strong impervious footing upon which to construct the floor. The clay was encountered at about 52 feet below the water level. Above it was a comparatively thin stratum of fine hard white sand, which was overlaid by a stratum not much thicker, composed of cemented gravel. Next above was a thick stratum of graded sand. Finally, a great layer of river silt overlay this sand and all the strata beneath. A good deal of this was pretty well known beforehand, so that as these strata appeared during the actual excavation they probably occasioned no surprise. But what was *not* known was the serious results that would ensue upon excavating through the sand and gravel overlying the red clay.

It had been expected to construct a dry dock similar to the new one building at Portsmouth, Va. The side walls of the structure were to be cellular. Pretty much all the excavation was to be done by means of a suction dredge. That is, the dredge was to excavate over the site down to about the desired level, a cofferdam having been put across the entrance to the dock. An earthen cofferdam had been partially constructed and some 460,000 cubic yards of material had been taken out. In fact, the floor of the whole excavation had been pushed down to 27 or 30 feet below low water. What happened then was that, when the dredge operated, the banks would slide in as rapidly as the bottom could be cleared. No side slopes of a reasonable character could be maintained. So the dredge was removed. The cofferdam was now finished and the site unwatered. It was then seen that the cutter of the dredge after penetrating through the river silt had entered strata that were heavily water-bearing. The continued falling in of the banks had resulted from the great flow of water.

After the dredging operations had come to an end, new bore-holes were put down with a view of correcting and confirming the earlier holes. The later holes showed that the stratum of red clay was continuous over the site and that it had an average thickness of about 18 feet. Underneath the clay was found a layer of fine sand well compacted, whose thickness varied somewhat. The finer sand was succeeded by coarser. The holes were continued on down to about 75 or 80 feet below low water, when it was seen that there was enough pressure on the water entering them to cause it to flow freely out of the tubes forming the casing of the holes. The heads of the casing tubes were about the level of the floor of the excavation as left by the dredge. The holes, or some of them, were pushed down 5 feet farther, when the water actually spurted out of the casing heads. The pressure back of these jets was ascertained by means of pressure gages. It was found to be 10.5 pounds per square inch. Now a hydraulic head increases at the rate of 0.434 pounds per square inch per vertical foot. Dividing 10.5 by this number, one gets 24 feet for the effective head acting on the water. The actual head would probably be something greater, as some loss is to be taken into account. The result of the discovery that there was a 10.5-pound pressure on the water was the inference that the Delaware River itself was the source of the water. This meant that the sand under the clay connected pretty directly with the river bottom not far away. In view of this line of reasoning it became important to preserve intact the clay overlying this deep sand. It was necessary to make sure now before proceeding farther, that a sufficient depth of clay would be left over the deepest areas required in the excavation. Furthermore, it was determined to avoid opening up any very large areas at any one time. One vertical foot of clay would balance, by its weight alone, two feet or more of hydraulic head. The under surface of the dock was to be at such levels, however, that at places not a great deal of the clay would be left in place to produce its restraining effect. Nevertheless, by working cautiously at such locations and by putting the concrete in at once the danger could be minimized. This was, accordingly, the general plan.

In order that the excavation might be properly carried down to the full depths required, and these extended to fairly low levels in certain parts of the bottom, steel sheet piling was driven to form a cofferdam all round the bottom excavation. The steel sheeting was driven well into the red clay. The length of the piles varied from 26 to 44 feet, depending upon the depth of the excavation required nearby. The side walls of the steel cofferdam were some 162 feet apart. The wall of sheeting completely enveloped the head end. It was thought desirable, too, to run transverse

## How a State May Grow a Timber Supply

By George H. Dacy

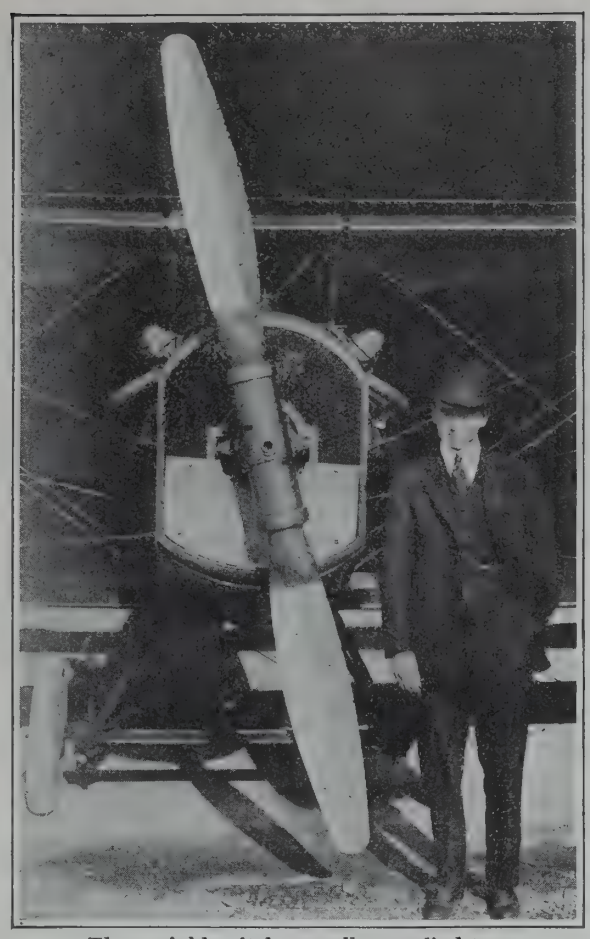
WITH all kinds of lumber in demand at higher prices than ever previously have obtained for building material of this description, the commercial possibilities of planting productive forests for potential utilization are beginning to appeal more attractively to those who, heretofore, have displayed little interest in reforestation projects. The most unique legislation now pending anywhere in the country in this regard is, at present, on the official gridiron at Springfield, Massachusetts. The lumbering resources of Massachusetts are rapidly being exhausted and official statements are to the effect that within the next score of years the State will have to import all the lumber it annually consumes from the Pacific Northwest. Such importations naturally will entail huge expenditures for freightage from the mills where the logs are sawed.

The business, lumbering and industrial interests of Massachusetts got together for a portentous pow-wow over the lumber situation. The result of this meeting was the submittal to the State Legislature of a practical and profitable plan for remedying the potential timber crisis in that State. It was ascertained definitely that there were about 1,000,000 acres of rough and scrub growth land suitable only for reforestation—so far as profitable production was concerned. The bill ultimately drafted proposed that the State purchase 250,000 acres of this land which could be bought for $5 an acre and seed down the entire tract to white pine trees. This work of planting would cost about $15 an acre while the maintenance charges including taxes would aggregate 70 cents an acre annually.

The bill proposes that the State issue and sell bonds to finance the project. It takes about 50 years for pine trees to reach maturity so that the bonds would be issued for that period. At the end of a half century, the value of the land per acre with the interest at four per cent compounded semi-annually would be $368.91. According to expert lumbermen, white pine of this character would yield about 30,000 feet of lumber an acre so that the stumpage value of the lumber at the end of 50 years would be approximately $600 estimating the pine at $20 a thousand feet on the stump, which is a conservative figure.

Thirty-one thousand voters have recently petitioned the Massachusetts State Legislature to pass this bill and at present are working to have a special election called to decide upon the issuance of the bonds. The consensus of opinion is that this project would be a good business venture for the State to embark in while it also would influence to keep the boys on the farms in the regions where the State forests were laid out. Under existent conditions, farm work is slack in the section under discussion during the winter months so that the farm boys have to go to towns and cities to secure jobs. The State forests would alleviate this condition as they would provide plenty of work for men and teams during the winter season when the pressure of farm work was lowest.

A State system of forests such as is outlined in this article would ultimately develop a permanent supplementary lumbering industry which would justify the year-around operations of the sawmills and the construction of small and permanent towns for the lumbermen and their families. And in addition to providing plenty of permanent work for the logging crews it also would occupy the idle labor of the adjacent farms throughout the year in such work as laying roads and trails, thinning the trees, patroling and protecting the forests against fire outbreaks. The permanent establishment of a large scale lumbering industry will develop a home market for all the surplus farm produce which the farmers desire to sell.



The variable pitch propeller applied to a standard airplane

## Varying the Airplane Propeller Pitch

By M. A. Henry

AT last the airplane has been fitted with "three speeds foreward and reverse." Government tests of the Hart variable pitch propeller recently made at McCook Field, Dayton, indicate that this device will accomplish for aircraft exactly what a gear set does for the automobile, greatly improving the efficiency of the machine.

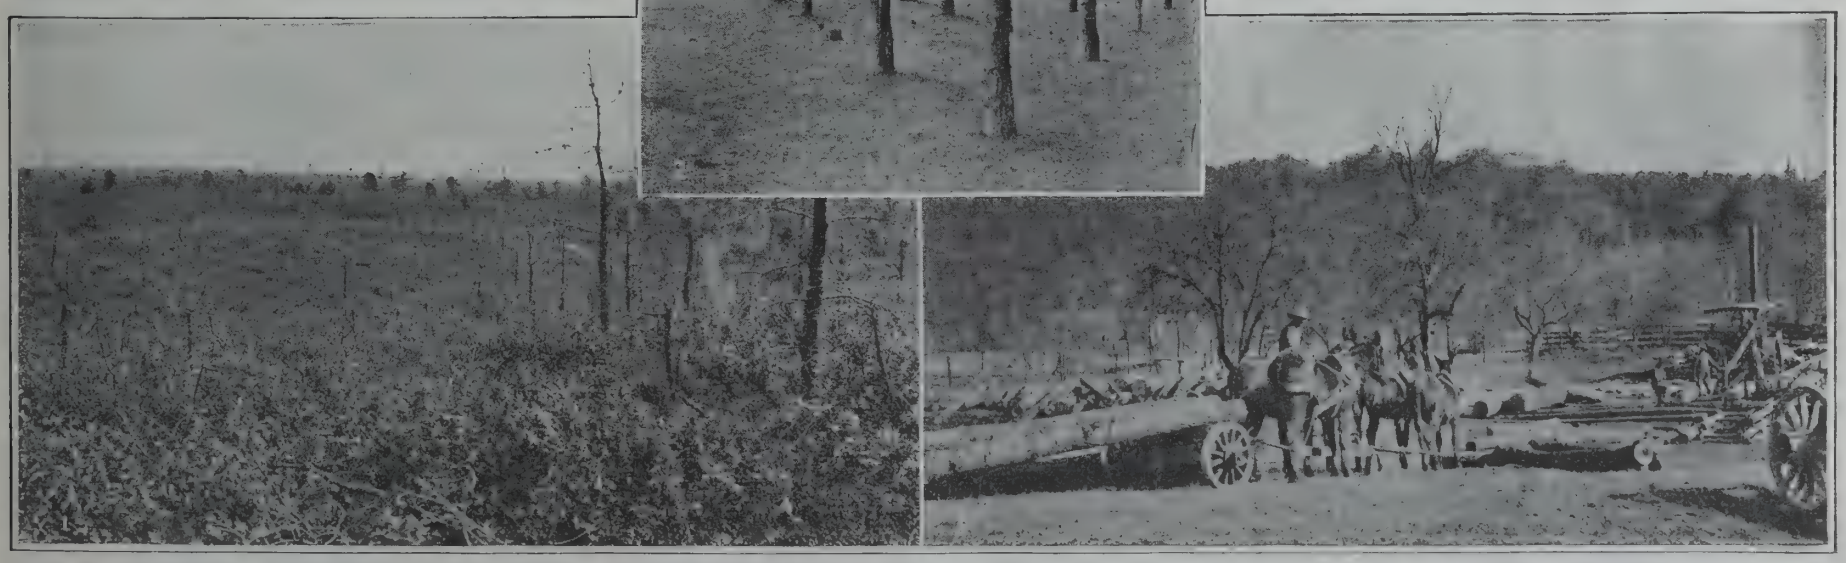
The new propeller permits the pilot to adjust the angle or pitch of the propeller while in flight by the simple movement of a lever. This permits maximum efficiency from both propeller and engine under all conditions, a thing heretofore impossible.

Thus in high altitudes, where the air is thin, the pitch is increased. This prevents the "racing" of propeller and engine. In long cruises, too, the propeller angle is increased and the motor throttled down. This effects a great saving in fuel and saves engine wear. In "taking off" a very narrow angle is used and it has been found that the machine can get off the ground quicker. Equipped with a variable pitch propeller a machine can climb faster and higher. In landing the pitch of the propeller is actually reversed and it becomes a brake, stopping the machine very quickly, once it touches the ground.

While the device was developed for military purposes, it is expected to be a big factor in commercial aviation, since it effects large savings in operating expense. The inventor is Seth Hart of Los Angeles, who brought his invention to McCook Field after some encouraging preliminary tests in the West which were described at the time in these columns. Word comes from France to the effect that excellent results have been obtained with airplanes fitted with variable pitch propellers. It appears that this idea is steadily gaining ground and must soon become a regular feature of aviation.

## Joseph Norman Lockyer, K. C. B.

THE cable announces the death in London, on the 16th inst., of Sir Norman Lockyer, one of the more prominent British astronomers. Sir Norman is a conspicuous instance of the amateur graduating into professionalism, having been in the first instance a clerk in the War Office, devoting his leisure to astronomical pursuits for which an education pursued at British and Continental universities amply qualified him. After a more or less unofficial commission under the auspices of the Duke of Devonshire, he was finally transferred, in 1875, after eighteen years of service at the War Office, to the Science and Art Department at South Kensington. Upon the foundation of the Royal College of Science he became director of the solar physics observatory and professor of astronomical physics. His greatest activity has always been in connection with solar eclipses, eight of the big British expeditions for the observation of these having been conducted by him between 1870 and 1905. In addition he has to his credit successful work in the spectroscopic observation of sunspots and the radial velocities of the gaseous prominences; and for many years he has been one of the leading investigators of the chemistry of the sun. In the latter connection he is the author of several books, both explanatory and speculative. Professor Lockyer passed his eighty-fourth birthday in May, and had naturally, of late years, permitted himself an increasing measure of retirement from active professional duties.



1. Land of this description worth $5.00 an acre and valuable only for lumbering is the kind Massachusetts aspires to purchase. 2. A white pine plantation 22 years old produced on barren sandy land which otherwise would be non-productive. 3. Such a State lumbering project would provide much work for farm labor and teams at periods of slack farm work

**Some pictorial aspects of the Massachusetts scheme for reforesting the barren lands of the Bay State**

# What Has Been Said About Einstein

## A Review of the More Important Popular and Semi-Popular Books and Articles in English

By the Einstein Prize Essay Editor

NUMEROUS prospective competitors for the five-thousand-dollar prize have written us, asking more or less baldly where they may inform themselves upon the subject of the Einstein theories. We have no serious expectations that Mr. Higgins' money is going to be won by anybody whose knowledge of and interest in the doctrines of relativity is of such recent growth that he has to ask this question. Nevertheless, the thing is possible; and since we have no desire to exclude anybody from the competition, the query as to sources is one that must be answered.

At the same time it may be helpful to some of the better informed among the competitors to have their own judgment of the leading discussions supplemented by that of another. And, too, the average intelligent reader—who will look forward to the winning essay and its close rivals to give him an understanding which he has not yet got of the Einstein business—will probably be more than willing to have his way paved toward profitable reading of these essays. So it seems in order from every viewpoint to say a few words here in review of the best of the books and articles which have appeared in English on the subject.

The first book which we shall mention is that of Dr. Eddington. Before reading this we knew that the author was entitled to rank as the leading authority on the subject, probably among English-speaking people and certainly in Great Britain. After we had read it, we knew why. His book bears the imprint of the Cambridge University Press; it bears the title, "Space Time and Gravitation"—just like that. We do not know whether the mark that is missing between the words "Space" and "Time" exists in the author's mind as a comma or a hyphen; either would of course be entirely appropriate. But no doubts regarding the punctuation of the title can cast the least question upon the outstanding merit of the book.

Compared with other volumes upon the subject which have been presented for popular or semi-popular consumption, Dr. Eddington's is fairly large. Compared with some of the strictly mathematical discussions of relativity which have appeared in other languages rather more freely than in English, it is not so imposing. And in fact, on examination it falls on the same middle ground which this casual inspection of its bulk might indicate. It is not for the advanced student of relativity, nor is it for the person who is entirely ignorant of the modern mathematics. Nevertheless, it will be read with appreciation by a very wide and varied audience.

We may, however, without contradiction, qualify this statement to the extent of making it plain that the book will be read in its entirety with complete understanding by few persons indeed. There are parts which assume more than a rudimentary knowledge of differential equations, to which many very competent students of mathematics never attain; and there are parts that call for no mathematical training at all. The larger part of the book lies between these extremes, and will be intelligible to anybody who knows what coordinate systems and equations of transformation are, and who is willing to adopt a few new terms and assimilate a few new ideas as he goes. At the same time there are parts that call for a great deal more facility in handling the concepts of experimental and theoretical physics than either the layman or the mathematician can reasonably be expected to possess; and there are other passages that demand a fluency in the methods of thought peculiar to abstract philosophy greater than we should expect to find in layman, mathematician or physicist. Then there are places where a physicist, a mathematician, or a philosopher would be thoroughly at home in the subject matter, but would probably take exception to the distance which the author has gone in the direction of humanizing his treatment. In a word, the book is written by a man who seems to constitute a rather remarkable combination of mathematician, physicist, philosopher, and plain human being; and only a reader who himself approaches such a combination will get through it without encountering some serious difficulty. The reviewer, for instance, tries to be a mathematician and a human being, but freely admits that as a physicist he scores an absolute zero, and that as a philosopher he is on a level little if any higher than this. But few indeed who possess any inclination to attack the book at all will not be able to read large portions of it with great pleasure and extreme profit.

For the man who has a good general knowledge of what relativity is about and how it operates, this is the book of all books to act as a clarifier of mental processes. We found no alarming quantity of material in it that was absolutely new to us; yet we felt after completing the book that our grasp of the subject had been largely improved. Dr. Eddington has a knack of exposing and illuminating obscure points of whose very existence one had not been explicitly aware; of bringing out with great force the inter-bearings of the various aspects of the subject; of interpreting in terms of the perceptual world about us the abstractions of the mathematical theory. Anybody who believes himself capable in his present condition of writing effectively upon relativity should be able to write more effectively after digesting what Dr. Eddington has to say.

We must not pass from this volume without quoting from the preface a passage which embodies admirably the spirit of the whole book. "By his theory of relativity," we are told, "Albert Einstein has provoked a revolution of thought in physical science. The achievement consists essentially in this: Einstein has succeeded in separating far more completely than hitherto the share of the observer and the share of external nature in the things we see happen. The perception of an object by an observer depends on his own situation and circumstances; for example, distance will make it appear smaller and dimmer. We make allowance for this almost unconsciously in interpreting what we see. But it now appears that the allowance made for the *motion* of the observer has hitherto been too crude—a fact overlooked because in practice all observers share nearly the same motion [when compared to the extreme of possible motion, which turns out to be the 186,000-mile-per-second velocity of light]. Physical space and time are found to be closely bound up with this motion of the observer; and only an amorphous combination of the two is left inherent in the external world [when we have isolated that external world from everything that inheres in the observer]. When space and time are relegated to their proper source—the observer—the world of nature which remains appears strangely unfamiliar; but it is in reality simplified, and the underlying unity of the principal phenomena is now clearly revealed. . . . It is my aim to give an account of this without introducing anything very technical in the way of mathematics, physics, or philosophy. The new view of space and time, so opposed to our habits of thought, must in any case demand unusual mental exercise. The results appear strange; and the incongruity is not without its humorous side. . . ." This is altogether the best passage we have seen anywhere in discussion of the new theories; and the viewpoint here laid down is carried with extreme clarity throughout the book.

If Dr. Eddington's book is the work par excellence for the serious student of relativity in search of an outline for his guidance and inspiration, Dr. Slosson's Easy Lessons in Einstein (New York) occupies almost an equally paramount position with reference to the wants of the person who admits before he starts that he doesn't know anything about the subject and doesn't want to pursue it too deeply. It is the misfortune alike of the relativity theory and of the world that this theory is not easily clothed in terms with which we are familiar. Indeed, it is still an open question whether it is yet possible so to clothe it fully. The above quotation from Dr. Eddington should make it clear why this is so. Einstein shows us that the external world as we have always seen it is an elaborate interweaving of that world as it actually is and as it has been conceived to be through our imperfect observations and the imperfect conclusions to which they have led us. A better example of just what this means and how it works has perhaps not been given than the one set forth by the present writer in an editorial in these columns under date of December 20th last. The ancients, it was here pointed out, in default of any knowledge of how gravity acts in other locations than at the earth's surface, or of the insignificant position which the earth really holds in the cosmic mechanism, or of the true shape of the globe on which we live, must have supposed "up" and "down" to be directions inherent in nature, universally the same. Eventually, with the realization that down was merely the direction toward the center of the body on which the *observer* happened to be located, the concepts "up" and "down" lost any universal significance which they might have been supposed to have; the part which they play in the external world about us was shown to inhere in the observer, rather than in that world itself. It was doubtless with some difficulty that the public at large, in ancient and medieval times, grew into ultimate understanding of this. It is with still more difficulty that we shall come to the parallel but more elusive understanding that the distinction always heretofore made between time and space, and the notion that time runs on forever in a straight line divorced from all dependence upon space, are likewise the contribution of the observer to the world of perception; that the facts inherent in the external world and independent of the observer are quite different.

The very circumstance that all this is so means that when Einstein effects his further separation between the observer's conception and the external fact, what he finds still inherent in the outside world is something new and strange, of which we have no mental picture immediately ready, for which we have no words and even no accurate analogies. This does not trouble the mathematician greatly, because he puts it all into a differential equation, and says that this equation characterizes the space-time which he has just found to be the true one of the external world, whereas a different equation characterizes a space-time of the sort we have had in our minds for the past few thousand years. Strange and incredible as it may seem to the non-mathematician, these differential equations, which on account of the uncouth symbols that appear in them he cannot even read, actually possess meaning to the mathematician and to him seem a sufficient expression and interpretation of what he is talking about. But the layman has got to get a whole new stock of ideas and perhaps even of words in which to clothe these before he can make much of the new doctrine.

Dr. Slosson presents a wealth of material in which such of the old familiar ideas and the old familiar words as come closest to portraying the new concepts are displayed with considerable skill. He exhibits a particularly happy inspiration in pointing out that the doctrines of relativity, in so far as they involve the recognition of a four-dimensional manifold of time and space combined, are not nearly so terrible as the mathematical jargon in which they are couched would make it seem. In a very definite sense, once we realize just what is meant by the term four-dimensional, this manifold is nothing new at all—"unless we are idiots we all think that way" and always have. It is merely the explicit recognition of this, and some of the details that such recognition carries with it, that are

(*Continued on page 212*)

*IN spite of several very candid opinions which have been expressed to the contrary, we cling to the belief that the Einstein competition is going to produce results that will stamp it as distinctly worth while. This, of course, implies that we expect some of the competing essays to surpass in actual subject matter and in the clarity with which this is set forth, anything that has yet appeared of comparable character in English. But this involves a comparison with what has appeared; and equally that this comparison may be made by others as well as by ourselves, and for the several other reasons mentioned in the text, we are moved to present this brief statement of what we have found best in the popular expositions of the Einstein theories. The list of books and articles which we find sufficiently good to mention here by title is indeed deplorably brief, and seems to show the inherent soundness of the donor's belief that there was room for further achievement in this direction.*—THE EDITOR.

## The Airplane in Mine Rescue Work

TO the constantly expanding uses to which the airplane is being adapted—patrolling forest fires, making timber and crop surveys, conveying census blanks in isolated regions, detecting the boll-weevil infested areas in Southern cotton fields, and eliminating distance between the doctor and his patient—is to be added another experimental effort. The assignment of airplanes as rescue workers in mine disasters is the hitherto untried development to be given practical application.

Negotiations are under way between officials of the United States Bureau of Mines and the Aircraft Service of the Army whereby airplanes will be given trial assignments in the mines of Illinois and Indiana. According to preliminary arrangements, in the event of a mine disaster, a plane from the nearest air-service station would be detailed to the headquarters of the district engineer of the Bureau of Mines. Here the air-going machine would be equipped with eight 40-pound oxygen tanks and dispatched promptly to the scene of impending trouble. Geophones, and a rescue car with its trained crew, could likewise be transported by the air route.

The United States officials have pledged co-operation when certain stipulations have been observed by the Bureau of Mines: Provide landing fields, with dimensions of at least 1,800 feet square, at each end of the journey; supply gas and oil at both terminals; and furnish the aviators maps of the route to be traversed. The equipment of desirable landing fields in much of the mining districts seems to be the difficult undertaking—not easy to be complied with in not easily accessible mining regions.—*S. R. Winters.*

## Thicker Aerofoils

A REPORT upon the aerodynamic properties of thick aerofoils suitable for internal bracing deals with the results of a series of tests conducted at the Massachusetts Institute of Technology wind tunnel, with a view to developing aerofoil sections thick enough to permit of internal bracing and the use of cantilever wings without any external bracing of the airplane wing truss. The sections tested were based on the Durand 13, and were varied in section form, in thickness along the span, and in chord along the span. Tapering both in thickness and in chord was found to be highly beneficial to efficiency, and some of the wings developed gave L-D ratios practically as high at angles corresponding to very high speeds of flight as the best of the wing sections for normal type, together with very much higher maximum lift co-efficients. In particular, it was found that the substitution of a thick tapered wing for R. A. F. 6 on a 3600-pound fighting biplane with Liberty engine would increase the maximum speed by 18 miles per hour, due to the saving in parasite resistance by entire elimination of the interplane bracing. A copy of this report may be obtained upon request from the National Advisory Committee for Aeronautics, Washington, D. C.

## Silver Fox Farms in Japan from Canadian Stock

ONE of the strangest and most interesting wild animal shipments left Vancouver, Canada on the steamship "Empress of Asia" the last week in February. The shipment consisted of six silver foxes from one of the largest fox farms in Prince Edward Island, eastern Canada, and was bound for Japan, where a syndicate is about to undertake fur farming. The foxes were valued at $5,000 per head, and were from a long line of domesticated stock, carrying a pedigree as notable as any famous horse or dog. The Japanese spirit of enterprise and their alertness to try any western form of business which promises good returns is most strikingly evidenced in their attempting to raise this producer of expensive fur in their own land. The climate of some parts of Japan, the representative of the syndicate claims, is sufficiently like the natural one of the Canadian foxes as to make the venture feasible. The animals while en route dined on chicken, choice raw beef, lamb and pork.—*By Francis Dickie.*

## British Tidal-Power Plans

IT is understood that a bill will be introduced into Parliament for the purpose of obtaining authority for harnessing a number of Scottish streams, investigations having revealed that the aggregate of available power is larger than had been anticipated.

With respect to the harnessing of the tides, it is reported that "work is about to begin both on the Dee and the Severn, where power can be produced—according to estimates of a group of engineers—at two-thirds the cost of electric power generated by coal. More than this, a number of estuaries on the west coast of England have been surveyed, where the cost of installation would be considerably lower."

The basic principle underlying most of the inventions for harnessing the tides is the working of a turbine by tidal ebb and flow. The tide makes the power at both its inflow and its outflow, only ceasing for a comparatively short time during the period of half tide. In one Cheshire and Lancashire district the great variation in the hour of the tide at neighboring estuaries makes possible, through an ingenious discovery, the production of maximum energy during an almost continuous period.

The plan for harnessing the tides devised by Lewis Woodhead, of Worcestershire, calls for the building of a cheap and efficient wall out in the sea or tidal river, in which turbines are placed. Mr. Woodhead claims that 10-foot turbines would be most economical where suitable, each of which would generate over 300 horsepower with a 5-foot head. Thus a mile of sea wall would be capable of generating 120,000 horse-power. The position of such a wall would be 4 to 6 miles from shore. The greatest difficulty, he stated, that has to be overcome is the possibility of obtaining a space 110 by 30 feet on the sea bed dry, but he claims to have discovered a method of insuring this, so that the wall can be well anchored in the sea bed.

## Glycerine

THE diversified uses to which glycerine is put indicate its importance in commerce. Most of the distilled glycerine finds its way into the manufacture of explosives, such as nitroglycerine, dynamite, and the more recently developed high explosives. These are generally a combination of nitroglycerine with guncotton or nitrocellulose, and the resulting product is known by a great variety of names. Commercially pure glycerine is a well-known reagent in pharmacy and medicine, where nitroglycerine itself is sometimes employed. Glycerine enters into a number of technical processes, such as the manufacture of soaps, inks, water-proof paper, and for the production of such plastic masses as printing rollers and other masses used in the art of reproduction. Glycerine is also used in gas meters and tubes which must withstand great cold, and for filling hydraulic jacks. It is one of the important items in sizing textiles and in that treatment of wine, beer, and vinegar known as "scheelizing."

## Disinfecting Barrels and Casks with Ultra-Violet Light

ULTRA-violet rays have long been employed for sterilizing drinking water, milk, and other liquids, but a new application of them in Germany reported in *Chemische Apparatur* (Leipzig) is for the disinfection of barrels and casks, particularly beer casks. For this purpose quartz lamps are lowered into the cask to be sterilized and the light turned on for fifteen to thirty seconds. It has been found inadvisable to continue the illumination for a longer time in ordinary casks coated with pitch, since the resultant rise of temperature causes the formation of fumes of pitch. The lamps vary in size according to the dimensions of the casks. In small and average size casks the time mentioned is sufficient to secure complete sterility. Some difficulty is met with in using this method for very large pitch-coated barrels, even when there is a corresponding increase of size in the quartz lamp and a suitable tension, for the reason that so long an illumination is required that the aforesaid fumes are produced. The method is not to be advised therefore except for barrels which are not coated with pitch.

## An Apple-Shipper's Makeshift

SHORTAGE of refrigerator cars has stimulated apple shippers of the Northwest to interesting makeshifts. In one recent season, a considerable portion of the British Columbia apple crop went to market in box cars equipped with stoves and stove-pipes. The shippers supplied men to care for the apples in transit, keeping the cars heated, and the apples arrived at destination in good condition.

A Chelan Falls, Wash., fruit shipper was confronted with a somewhat different problem this spring when he had 26,000 boxes of apples to market, and couldn't obtain refrigerator cars. He could not tell what kind of weather the apples would encounter en route to Cleveland, Ohio, where he planned to market them, but average seasonal weather would involve danger from heat rather than from cold, and he made his plans on that basis.

He obtained box cars and had a false floor placed in each. Beneath this false floor was sawdust, soaked with water to provide the apples with moisture. He accompanied the train of 28 cars, and saw to it that each night the car doors were opened to allow the apples to cool off.

Happily, no unfavorable vicissitudes of weather were met with. In Montana, the temperature got down around 25 degrees and froze the water in the sawdust. This tended to keep the apples cool throughout the remainder of the trip.

The train went through to Cleveland in nine days, much less than the usual running time. When the apples were unpacked, they were found in excellent condition. On the average, for the season, the makeshift was well calculated to be successful, but the shipper admits that a bad cold wave would have been serious. He had to take a risk somewhere.

## The New Floral Clock

SINCE Linnaeus worked out his floral clock the list of available subjects has been very much increased. This is due to the introduction of fresh kinds of plants and also owing to the fact that new varieties of the old ones frequently show a variation in the time of opening their blooms.

The chief difficulty in putting together the list of subjects for the floral clock has been that they must all flower at the same time of the year, preferably in the summer months of June and July. Also the twelve species selected must expand their blossoms in successive hours from six in the morning to five in the evening. After a large amount of experimenting the following selection of plants has been put together and this is claimed to be the most perfect list for the floral clock up to date. Slight variations in the times of opening might occur in different localities, but it is remarkable how closely the various plants adhere to the times of opening. The times of the expanding of the buds are in all cases put before the name of the plant: 6 a.m., Yellow Hawkweed (Hieracium aurantiaca); 7 a.m., Marigold (Calendula pluvialis); 8 a.m., Venus' Looking Glass (Specularia speculum); 9 a.m., Corn Marigold (Calendula arvensis); 10 a.m. Clovewort; 11 a.m., Mountain Dandelion (Taraxacum montanum); 12 a.m., Fig Marigold (Mesembryanthemum); 1 p.m., Single Pinks (Dianthus); 2 p.m., Pyrethrum corymbosum; 3 p.m., Red Hawkweed; 4 p.m., Lady of the Night (Mirabilis dichotoma); 5 p.m., Catchfly (Silene noctiflora).—By *S. Leonard Bartin.*

## Air Conditioning

IT is only lately that the proper conditioning of air has been recognized as a subject of fundamental importance in many industries. The possibilities of overcoming unhealthful air conditions are of course extensive and a secondary consideration is the aid to manufacturing processes which satisfactory atmospheric conditions give.

In the production of gelatine products, low temperatures and constant low moisture conditions must be maintained. In confectionery establishments cool, dry air becomes a requirement. In the baking industry a high humidity with proper temperature maintained constant, eliminates important variables in the raising of dough and enables the baker to standardize time. In the photographic industry the proper conditioning of air has been practised for some time, for otherwise there would be many days too hot or too damp for the production of satisfactory material. Even the printing art requires the conditioning of air, where several colors are used in the production of illustrations, for the perfect registration necessary for success cannot be expected under greatly varying atmospheric conditions. The silk industry has practised conditioning for a long time, but we have not yet been able to extend this work into the wool and cotton field. In modern textile mills, however, apparatus is being installed by means of which the condition of the air can be satisfactorily controlled.

## A New Cyanide

THE development of a process for obtaining cyanide from cyanamid was recently reported before the New York Section of the American Electrochemical Society. It marks another accomplishment in the field of American electro-chemistry. The work has progressed rapidly, and the statement is made that in a few months more was accomplished than had been achieved abroad in fifteen years. Three months after starting designs for the plant, four tons of equivalent sodium cyanide were being produced each day, the grade being unusually high. Within a year a single small electric furnace of the continuous type was producing a very satisfactory cyanide at an unusually high efficiency.

The product is said to be uniform in quality, to possess desirable physical characteristics, and to be competing with the pure high-grade cyanides for markets where the latter has long been intrenched. The material is adapted for case-hardening, may be employed in the electro-plating industry, in connection with precious metals, and the preparation of pigments and prussic acid.

# Fire Without Firemen

## How the Coal Is Fed Mechanically to the Huge Grates Beneath the Modern Boiler

By H. A. Mount

WE are all worshippers of the colossal. The biggest steamship, the tallest building, the longest bridge never fail to interest. And in our admiration of big things we ofttimes forget the little things which make them possible.

Imagine, for instance, ye who have fumed over the family furnace on a cold day trying to fire by hand, one of the great modern steam boilers, with a fire grate 27 feet wide, that consumes more than six tons of coal every hour!

We hear very little of the mechanical stoker and yet it is one of the biggest "little" things of modern industry. Without it our whole scheme of power generation would have to be revised. The mechanical stoker was originated, not so long ago, to replace the grimy workman, whose sweat-gleaming torso, lighted by the furnace glare as he heaved shovelful after shovelful of coal, furnished one of the oftenest-pictured features of industry. But today the mechanical stoker finds a much wider usefulness.

Boilers which a few years ago were hand-fired are machine-stoked today with an increased efficiency of from 25 to 50 per cent. The amount of power used in this country has been increasing in recent years at a terrific rate. The mechanical stoker has made it possible to meet this increase, not by multiplying the number of boiler units, but by increasing their size.

The capacity of a boiler obviously depends directly on the amount of coal that can be burned under it. This in turn is governed by two factors; the area of the grates and the amount of coal which can be burned per hour on each square foot of grate surface. Mechanical stokers make possible the use of huge grates which would be impossible to fire by hand, and at the same time allow the coal to be burned with maximum efficiency.

Undoubtedly, had the mechanical stoker not been invented, we would have seen fuel oil and gas used to a much greater extent than at present. The stoker gives the same even, continuous fire with a low grade of coal, as can be had with either of these fuels, which cost approximately three times as much to burn.

There are available a number of types of automatic stokers, each of which has its sponsors. Two of these will be described here and they are representative, in a general way, of the whole field.

The simplest of these, and the type most generally used, consists of a fuel magazine or retort inside the furnace, to which leads a conveyor pipe. In the conveyor pipe is a screw or worm conveyor which constantly pushes a supply of fuel into the bottom of the pot. The fuel is ignited on top and the fire bed is formed on the upper edge of this magazine. The rising fuel from below causes the fire to overflow from the retort to sloping grates on each side.

As the coal moves upward through the fire-box and approaches the fire it is slowly roasted and coked. The released gases, mingled with a controlled supply of fresh air, ignite and burn as they pass through the blazing bed of coke above. The coal is delivered to the grates as coke and the continuous feeding gives a breathing motion to the coke bed, keeping it open and free for the circulation of draft. The coal is fed into a hopper on the outside of the furnace, either by hand or by machinery.

One of the prime essentials of the device is a method of producing a forced draught through the fuel bed, which can be closely controlled. The air is furnished by a blower or fan, operated by steam from the boiler or by electricity. The air is conducted to a wind box located beneath the retort and is distributed through tuyeres communicating with it. The distribution of air is regulated by a wind gate at the mouth of the wind chamber. The tuyeres are the only parts subject to destruction by heat and these are detachable so they can be quickly and cheaply replaced.

Due to complete combustion through the coking process, low grade coal can be used. The fact that it is seldom necessary to open the fire doors while the stoker is in operation effects another saving, estimated in some plants as high as 20 per cent. Ordinarily the fire doors may be kept closed for periods from six to eight hours. The largest saving, however, is due to the air control.

When it is considered that about fifteen pounds of air are required to burn one pound of coal, and that of this four-fifths is inert nitrogen which must be raised to furnace temperature but which does no work, the importance of using only the precise amount of air needed is realized.

The stoker forces the coal upward and into the fire and over the tuyeres. The tuyeres discharge the air into the coal at the points where the gases are liberated during the coking process. The gases ignite and pass off through the incandescent coal bed without smoke. The air is introduced under pressure to enable it to penetrate the coal bed where it is thickest, where it requires the most air and where there is the most resistence to a natural draft.

The forced draft equipment is a very important part of an underfeed stoker. A sufficient volume of air must be forced through the fires to burn the maximum amount of coal intended, and this naturally depends on the size and design of the ducts and the amount and kind of coal which it is proposed to burn.

A variation of the type of stoker just described injects the coal into the retort by a reciprocating plunger, which is actuated by a steam-driven piston in front of the boiler. The plunger has mounted on it several pushers which carry the fuel along with them on a forward movement, but slide through the coal in the reverse direction. This type of stoker also is usually equipped with grates with moving fire bars. As the coal rises in the retort it is distributed to the sides of the grate by the moving bars. Every other bar in the grate is made movable by mounting one end on a rocker rod, which is actuated by the same piston which moves the fuel injector. In very large boilers as many as three of these units may be mounted side by side. The ash is drawn off from trays between and at the sides of the units.

Automatic control may be provided for these stokers so that the only duty of the fireman is to dump the ash trays occasionally.

The second type of stoker is radically different in construction from those just described. In it, the fire grates take the form of a slow-moving endless belt, on which the coal is carried through the combustion chamber, being gradually consumed as it moves, and being dumped as ashes at the rear. This type of stoker is particularly adapted to very large boilers which have to meet sudden overloads, as those in large powerhouses.

Forced draft is also provided here and by varying the volume of air drawn through the fire the speed of combustion can be closely controlled. By raising or lowering a gate under which the coal passes from a hopper on entering the combustion chamber the amount of coal can be quickly regulated. The draft and amount of coal must be so regulated that the coal is completely burned and only ash and not live coals is dumped at the rear. The grates may be driven by steam motors or turbines, using power from the boiler, or by electric motors.

The grates are made porous to allow the passage of air from beneath. One advantage of this type of stoker is that all of the burned material is dumped at each revolution of the grates and there is no trouble from clinkers or obstruction of the fire by ashes.

Not only have automatic stokers replaced hand firing in nearly every important power house, but they are very important equipment in some of our big industries. They are used for instance in many annealing furnaces and in the big forges where steel ignots weighing tons are heated. It is desirable in

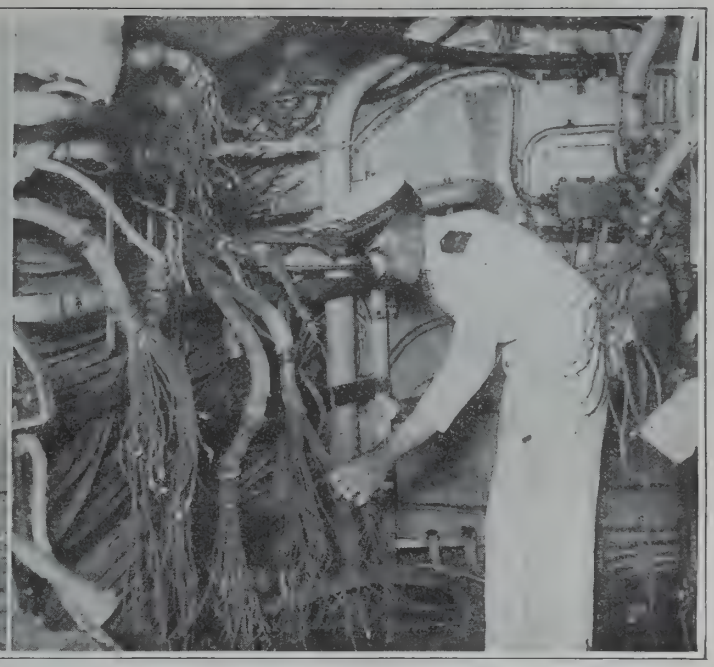
**The surrendered German dreadnought "Ostfriesland" as she steamed into New York harbor. She will first be carefully studied and then shot up in target practice**



**This shows how the Germans wrecked the electrical wiring—the nerve system of the ship**

## The Surrendered German Battleship

IF anyone asks why the surrendered German warships have little or no value for the United States Navy, one suggestive answer can be found in the characteristic picture which we publish, showing the destruction wrought by German hands on these ships before they were surrendered. What they did to the electric wiring (which may be called the "nerve system" of a battleship) was matched by other destructive work to the fire-control mechanism, gun telescopes, range finders, compasses and a hundred other of the important details of battleship equipment.

The "Ostfriesland" formed one of the second group of dreadnoughts built for the German navy. Her sister ships were the "Thuringen," "Helgoland" and "Oldenburg" In designing them, the Germans repeated the tactical mistake which they made in the previous, or Westfalen, class; for they placed the six two-gun turrets in such a way that at no time, and on no line of bearing, can more than eight out of her twelve twelve-inch guns be brought to bear upon the enemy. These ships were laid down in 1908 to 1909, and it was not until five or six years later, when the Germans built the "König" class, that they placed all of the turrets on the central line of the ship—a practice which we have followed in our navy since 1906, when we laid down our first dreadnoughts, the "South Carolina" and "Michigan."

The "Ostfriesland" is a ship of about 23,000 tons displacement, with an eleven and three-quarter-inch main belt, reducing to six inches at the bow and four inches aft. The turrets are protected with eleven and twelve inches of armor, and the six-inch battery, which musters fourteen guns, has six and a quarter inches of protection. The ship has the great beam of 93¼ feet—this in order to allow for wide anti-torpedo spaces between the outside of the hull and the vitals of the ship. She is a triple-screw ship designed to be driven at twenty knots with 25,000 horse-power. Like all German battleships which were designed merely for the North Seas, her steaming radius is so limited that she would be useless for the world-wide activities demanded of ships of our own and the British navy.

## Oil as a Locomotive Fuel

**By Charles N. Winter**

OF the many readjustments necessary to meet the changed conditions throughout the entire world, none is more important than the subject of fuel for locomotives, particularly in places remote from the sources of coal—the most commonly used fuel. The greatly increased cost of mining coal and transporting it long distances has raised the price to a point making its use as a locomotive fuel prohibitive in many parts of the world. This has a direct and far-reaching effect on the ultimate cost to the consumer of every necessity of life, hence concerns not only those who own and operate the railroads, but every person in every station of life.

Many experiments have been resorted to—burning of wood, maize, etc., but for general utility and economy oil has proved to be the most satisfactory substitute for coal as a locomotive fuel, and its use is increasing.

The coal shortage in Argentina led to a great increase in the use of wood, but due to its great bulk and the increasing difficulty of replenishing the supply, the hauling of wood became a great volume of the railroad traffic and threatened to become a monumental task. It soon was realized that more suitable fuel must be procured. Illustrative of the extremities resorted to in Argentina is the reported burning of maize as locomotive fuel. The fuel problem in that country has been partially met by equipping locomotives with oil-burning appliances and agents are now in the United States investigating the most economical methods of using oil fuel.

Pulverized coal is being burned successfully and experiments are being made with colloidal fuel—a mixture of pulverized coal and oil—but these methods require a somewhat complex apparatus and they cannot, as yet, be said to be generally applicable.

Another method being given consideration by some combustion engineers is the generation on the locomotive tender of producer gas which would permit the utilization of inferior grades of fuel now useless as locomotive fuel.

Oil-burning locomotives are by no means new, having been used in some parts of the United States and in other parts of the world for many years, but where coal has been available it has generally been used.

It will be interesting to those not directly concerned in railroad operation to learn of some of the means employed to burn oil as locomotive fuel. There are many different means employed to feed the oil into the locomotive firebox, but the general construction of such apparatus is substantially constant. Briefly the cycle of operation is as follows: The oil is fed by gravity from the oil tank, on the tender, through the oil heater and piping, to the burner, where it is vaporized and blown by a steam jet or a steam-and-air jet into the firebox and ignited by a piece of burning waste thrown in through the firedoor.

Two most important parts of oil-burning apparatus are the oil heater and the oil burner. One heater consists of a cylindrical chamber through which the oil flows on its way to the burner, and is heated by steam passing through the pipes contained in the cylinder. Another type reverses this procedure, the chamber containing the steam and the oil passing through the pipes. Still another type consists of two concentric tubes enclosed in a cylinder, the oil flowing between the surfaces of the inner and outer tubes and being heated by steam, which occupies the space inside of the inner tube and outside of the outer tube.

The use of the heater is resorted to in order to reduce the viscosity of the oil and at the same time to raise its temperature to a point just below vaporization before blowing it into the firebox.

Numerous designs of oil burners have been used successfully, but they may be grouped into two general classes; those in which the oil and steam, or steam and air, mix and vaporize the oil inside of the burner; and those burners with which the mixing and vaporization takes place outside. Some burners of the outside-vaporizing type have a projecting corrugated lip which assists in atomizing the oil as the steam impinges on the corrugations. Usually in the inside-mixing type, the oil flows through the top chamber and meets a jet of steam and air which vaporizes the oil just inside of the outlet to the firebox.

The conversion of locomotives from coal burning to oil burning is comparatively simple and inexpensive. The oil tank can be installed in the coal space of almost any locomotive tender and the oil-burning apparatus installed in the locomotive itself with very little alteration to the firebox. This is already being done on certain divisions of a number of railroads in the United States. The Seaboard Air Line recently installed oil burners on all locomotives on a southern division of the road and has contracted for an immense supply of oil for a long period. The Santa Fe System, the Southern Pacific and other railroads of our Southwest have many oil-burning locomotives and are planning an increase in such equipment.

For months past the railways of France and Spain and other European countries have had engineers in America gathering data on the subject of oil as a locomotive fuel and the equipment of a great part of their locomotives with oil-burning apparatus is begun.

Fuel oil is found in many parts of the United States, in Mexico, in Argentina and other parts of South America, in Rumania, Russia and elsewhere, and as it may be handled with much greater facility than coal it is destined to come into more extended use as a fuel.

A conservative estimate of the relative heating value of oil is that three and one-half barrels of oil are equal to one ton of coal, which, at the prices of the two fuels, would effect a saving of from 20 to 40 per cent in fuel cost, to say nothing of the lower cost of handling oil as well as other operating economies. Thus, the ease with which the fireman can manipulate the oil-burning controls makes it possible to secure a very high degree of economy in the use of oil.

# Wood That Is Stronger Than Steel

## How Thin Veneers and Water-Proof Glue Have Conspired to Build a New Industry

By Robert H. Moulton

THE weakness of wood is in its grain—the fact it is made up of a bundle of fibers. Each of these by itself will stand a considerable pull, but each fiber in the bundle is held loosely to its neighbors on all sides. To make a wood that is capable of standing strain in all directions, it is necessary to combine several layers cut at various angles to the grain. Thus is made "plywood," said to be literally "stronger than steel." It is revolutionizing airplane construction, and it will enter conspicuously into postwar industry. It is even possible that as a wall-covering the thinner varieties will compete with wallpaper; they possess all the beauty and durability of heavy wood paneling, for their composite nature prevents them from warping. Thin plywood has been found, in toughness and flexibility, to compete favorably with textile fabrics in the manufacture of airplane wings.

If anyone should say offhand that, weight for weight, wood was stronger than steel, he would be laughed at. However, the Forest Products Laboratory at Madison, Wis., which is responsible for our knowledge of plywood and the various uses to which it may be put, has devised a testing machine which proves this very thing; only, of course, the strength of the wood is estimated by the pull it will stand running with and not against the grain. For example, a toothpick of pine wood placed in this machine and weights applied, with the idea of pulling the toothpick apart in the middle, will usually stand a pressure of from 75 to 100 pounds before it gives way. As against this, a 3-inch length of steel wire, of the same *weight* (not the same daimeter) as the toothpick, generally gives way when the tension reaches about 30 pounds. Various tests with this machine have shown that all of the denser woods can beat steel by from three hundred to six hundred per cent. When tested across the grain, however, the best of wood shows only from one-fourth to one-half the strength of steel. That's why plywood was invented.

The panels used in the manufacture of plywood vary in thickness according to the article to be made of it. In the case of material for airplane wings, for example, they are only .01 inch in thickness. Gluing thin veneer into a very thin panel of plywood has always been an extremely difficult matter for the manufacturer. The principal cause of trouble has been the excessive swelling and shrinking of the thin plies due to their absorption of water from the wet glue, which causes overlaps and a considerable amount of wrinkling. A second source of trouble is in the handling of the very thin material when it has been coated with a wet glue, since it is very fragile and easily ruined when handled wet.

To overcome these difficulties the Forest Products Laboratory has evolved a process which consists of making a sheet of glue by coating thin sheets of tissue paper with blood glue, allowing it to dry, and using the coated paper as the glue layer for plywood. The process of making the panel then consists merely in laying alternately as many sheets of thin veneer and sheets of this glue tissue as may be required to build up the panel desired. These sheets are then pressed in a steam-heated press which activates the glue. The result is an extremely thin panel in which the moisture content has been changed not more than one or two per cent. This simple method eliminates the troubles resulting from the use of a wet glue, and makes the handling of the thin material an easy matter.

The extremely thin plywood secured in this manner and tested on airplane wings built especially for the purpose proved surprisingly strong. It was found that it gave between six and eight per cent added lifting power over the linen ordinarily used, by reason of the fact that the "flap" of the cloth is entirely eliminated. Weight for weight, its strength proved to be approximately the same, and it is quite likely that in the future all wings may be covered with this material.

When plywood was first thought of in connection with airplanes, an apparently insurmountable difficulty presented itself. A machine that had to be out in all kinds of weather and spend much of its time in a dense fog and in thick clouds—often approaching 100 per cent humidity for long periods—must not be held together in any way by glue that water would dissolve. To overcome this difficulty two new glues were evolved

(*Continued on page 212*)

**Fifteen stumps a day without dynamite**

## The Tripod Stump-Puller

THE direct application of the power to uproot the stump vertically instead of at an angle, so that the useful component of the force exerted is practically that entire force instead of half or less thereof, and the virtual absence of a hole to be filled where the growth is displaced, are among the virtues claimed for a tripod stump puller which we illustrate herewith. The machine is powerful and is capable of lifting huge stumps without the assistance of dynamite, although the use of the latter is a valuable ally in cracking the securely intrenched tree growth.

The tripod pullers, with respect to types, are threefold in number, screw, windlass, and lever machines, the last-named being more widely used. No anchor stump is necessary in using the lever pattern, the puller being set immediately over the stump and the machine is moved for each succeeding performance. The stump is displaced by chains encircling one of the larger roots.

The tripod stump puller has proven its efficiency in uprooting huge white and Norway pine stumps growing in the sandy soil of Michigan, and has a limited use in the Mountain and Pacific Coast States as well as the South. Four men and an equal number of horses constitute an efficient working unit, the Office of Farm Management, U. S. Department of Agriculture, having assembled data indicating that on five tracts of land crews averaged 79 stumps a day for over 140 days. The tripod machines cost from $125 to $200.—By *S. R. Winters.*

## A Big Lifting Barge

THE accompanying picture shows the largest derrick barge on the Pacific doing a rather novel stunt—lifting a building tower at the shipyards, and moving the tower a distance of about one block. The tower weighs about 65 tons, is 65 feet in height, and carries two derricks on its deck, one of these being 100 feet in height.

A number of cables were connected to various parts of the building tower and the derrick barge walked off with it easily. Had it not been for this barge it would have been necessary to take the tower apart, which would have required much time and entailed quite an expense.

The new barge recently performed another novel job. It lifted a 150-ton deckhouse from topside of a steamer and with great ease deposited it on a nearby wharf. The task under the old system would have consumed several days and the labor of a gang of men. The work was done by cutting the deckhouse in half and transporting each 75-ton half.

A short time ago the derrick barge succeeded in pulling a new steel tanker from the mud after a number of powerful tugs had worked three days and failed. The owners were preparing to dredge around the tanker, which was on the mud a distance of about 50 feet. The top lift line and the heavy load line of the barge were connected to the tanker and she was pulled back into the water in half an hour.

The steel derrick, it is estimated, will be able to lift the stern of a big vessel well out of the water so as to enable the workmen to replace a propeller, and the vessel would not have to go into dry dock. Above the wooden hull towers a triangular girder frame of steel 85 feet high. The boom is a lattice girder of steel 100 feet long and is designed to take 100 tons at a 50-foot radius and an 18-ton weight on its maximum working radius. Complete electric outfit is provided and a large air-compressor for working drills and other tools, or for supplying air to pontoons, or for forcing water out of wrecked hulls. Living accommodations are provided for a large crew of men and the barge carries sufficient fuel and fresh water to remain outside on a wrecking job for several weeks at a time. A feature of this barge is the hydraulic weighing machine. This device records the object lifted to the minimum of a pound.—By *C. W. Geiger.*

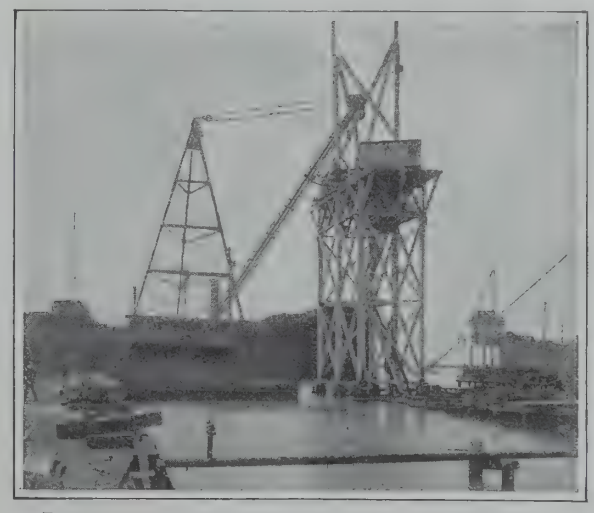
## Barrel Rigged to Haul Water

OFTEN the farmer needs to carry water about the premises in larger quantities than could be carried in a bucket by hand. Even if a water system is employed he does not care to install an extra conduit to such places as the temporary hog watering trough, the concrete mixing vat, the garden to water crops during an extended drouth, etc. The photograph herewith shows how one farmer rigged a 50-gallon kerosene barrel to be easily carried full of water by rolling it on the ground to any desired place on his farm Description of how this outfit is put together is superfluous.

The barrel is filled by removing the bung plug or stopper and then replacing it till arriving where the water is desired when it can be removed to draw out the water; the man whose outfit we illustrate has a faucet screwed into a hole bored in one of the heads to draw the water as needed, taking it out and putting in a short wooden stopper in its stead that will pass the shaft pieces when the barrel is rolling. The lag

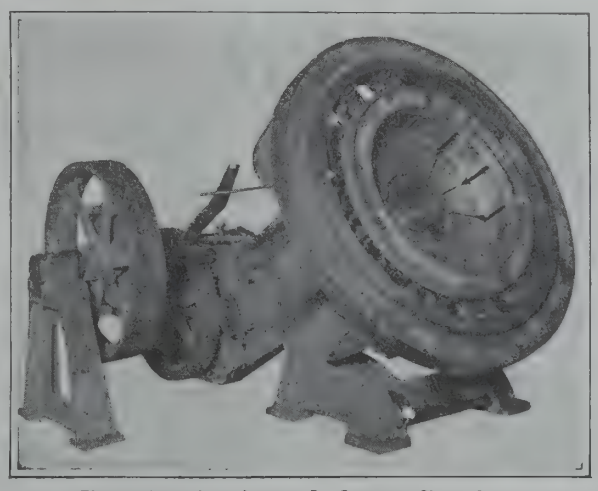
**A "lawn" of concrete and green paint**

screws form spindles for the rear ends of the shafts to turn on and the load can be carried up considerable grades without much effort. One might think it would not be a paying idea to consume the necessary time

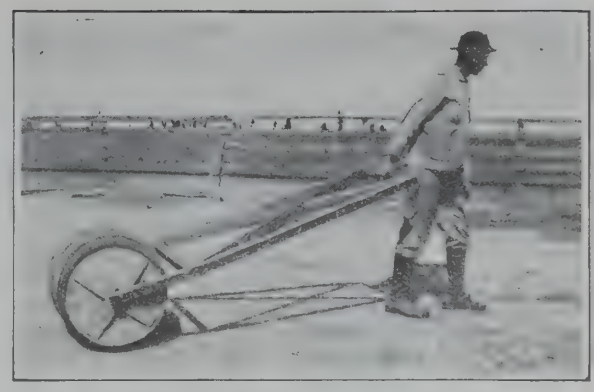


**Barge-mounted derrick that gives good service in San Francisco waters**

to prepare this rigging but it is to be considered that when a haul is made with this barrel you have fifty gallons where it is needed, whereas you would perhaps not have more than two with a bucket. Nothing



**Upsetting rims instead of expanding them**



**A handy substitute for the water bucket**

needs to be done to the barrel more than to bore a hole in one of the heads to draw off the water as desired if you prefer it to the bung hole in the side and there is but a trifle of expense to buy the material needed, only a few nails, two lag screws, a few scantling, etc.—By *L. M. Jordan.*

## The Concrete Lawn

THE waterless, mowerless, weedless, gopherless lawn has made its appearance in Los Angeles, according to a recent item in one of the local papers. Everything about this lawn is according to the usual specifications governing be-grassed and be-flowered front yards, with the single rather important exception that the "lawn" is of concrete, painted green. At a distance it doubtless looks pretty much like a grass lawn, though at close quarters we should think it might leave something to be desired, unless the proprietor (and inventor) has gone to the trouble of painting in individual blades of grass. The idea, of course, is to have a lawn that will stay fixed without any fixing—no mowing or cutting, no seeding, no rolling, no bare places, no trouble of any sort. Just how many people who care enough for the open to live in a neighborhood where the lawn problem exists, would be satisfied with this counterfeit presentment of a sure-enough lawn we do not know, but for all such, here is the idea.—By *Frank B. Howe.*

## Mounting Pictures Smooth and Flat

HOW many times have you pasted down a paper or mounted a print to find that when it dried it had buckled disappointingly? Ordinarily the paste is applied on the mount, the difficulty being that the exact limits to be thus covered is a matter of guesswork to meet the uncertain expansion of the print which is immersed in water before mounting; with the result that the print often exceeds the predetermined limits of the amount of the area covered with paste to receive it; on the other hand the print frequently falls within this area, leaving a margin of irremovable paste. The following method is free from such objections and difficulties: Keep the mount flat and with a small wad of cotton wetted in clean water, slightly dampen the approximate area to be covered by the print. Cover the back of the print with paste—preferably arabol—smooth and thin. Apply the print to the mount and with aid of a paper blotter and a small roller, smooth the print from its center outward. No paste will appear outside the limits of the print; any dampness exceeding these limits will evaporate. Any paper shreds left by the blotter, etc., may be wiped clean from the print's surface with the same damp wad of cotton.

## Tire-Rim Upsetting Machine

IN welding tire rims the method commonly used has been to weld the rim with the diameter less than the size required, and afterward expand the rim while cold to the correct diameter. For this purpose a tire-expanding machine was used and a low carbon steel is required as high carbon steel is more liable to break in the stretching process. In order to use the upsetting principle to obtain the correct diameters a new machine has been developed by a Chicago manufacturer. This machine contracts a tire rim to the correct size instead of expanding it. It differs from the usual tire setting type of machine in being motor driven instead of employing hydraulic power and the rim is held nearly vertical instead of in a horizontal position while being contracted. A toggle motion controls the jaws or dies and a combined movement of 3¼ inches across the diameter of the circle is obtained. The machine in operation runs continuously and makes eight strokes per minute. A wedge adjustment operated by a handwheel is provided to take up wear or to suit special conditions.—By *Allen P. Child.*

# Items In Brief

*A Department Devoted to Current News in All Fields of Pure and Applied Science*

## *Power and Fuels*

**The Gasoline Situation.**—There is no mystery in the existing shortage of gasoline on the Pacific Coast. It is not a case of diminished supply—the Far West has never had so much gasoline as this year—but one of increased consumption. The refineries of California are this year manufacturing a greater volume of gasoline than last year, and great quantities are being brought to the Far West from Mid-Western fields and Mexico. Yet, this larger supply does not satisfy the enormous demands of the scores of thousands of additional automobiles, trucks, farm tractors, gas engines, pumps and other equipment dependent upon gasoline for power.

**A New Heating System.**—Building superintendents and heating engineers will be interested in a piping layout for a heating system that provides a closed-loop circuit, whereby the water of condensation from the radiators is returned directly to the boiler. With the system is used a duplex boiler feeder, according to *Power*, which permits a continuous flow of condensation into the boiler. The condensation is held under pressure and is delivered into the boiler at a temperature only one or two degrees below that of the steam, corresponding to the pressure carried on the heating system. These results are obtained without the use of a receiving tank. There are no vents open to the atmosphere and practically no heat loss.

**Cleaning the Air** for internal combustion engines without materially reducing the engine power is a problem that has received considerable study, and a number of devices for the purpose have resulted. One of the more recent of these deposits the dust on the walls of a winding passage kept wet with oil. The upper portion of a disk which revolves at about ten revolutions per minute, intercepts the air, and as the revolution continues, the dust is washed off and settles in the oil bath, from which it is removed as required. Cleaning the device is said to be an easy matter. It is claimed that power loss due to the cleaner is greatly reduced because the air is not required to pass through the oil and the air flow is therefore not strangled.

**Natalite—A New Motor Fuel.**—It is reported by the London Automobile Association and the daily press that natalite, the new motor fuel (so called by reason of its discovery in Natal, South Africa), has been in use in that country for some time past, is well spoken of, and has had many favorable reports upon its practicability as a gasoline substitute. It is said to be a by-product of the Natal sugar industry, and is reported to be a mixture of power alcohol and ether, capable of great development, in view of the large tracts of waste vegetation available in South Africa. A British research committee is now engaged in making regulations respecting the use of this fuel, especially the necessity of denaturing the liquid to prevent its possible use as an intoxicant.

## *Transportation*

**The U. S. Navy's Swiftest Vessel.**—Steaming at the rate of 38.257 knots, the U. S. "Satterlee" in her recent official trials broke all American speed records. The best previous record made by an American war vessel was 37.04 knots. The "Satterlee" is driven by two 14,000-horse-power Westinghouse compound turbines which developed 31,223 horse-power and broke all records for vessels of this, the destroyer, class.

**The Very Necessary Horse.**—The regular dealers in New York City who make a business of purchasing high-class draft horses and assembling them in pairs report that they have never had such a demand for good draft horses and that prices have never been as high as during the months of March, April and May of the present year. The reason for this is that horses and mules are still the chief source of motive power in agriculture and draying. They have been read out of existence a good many times in the world's history. Nevertheless, the United States Census for 1910 revealed 19,833,000 horses and 4,210,000 mules on farms, and the estimates of the Department of Agriculture for January 1, 1920, show 21,109,000 horses and 4,995,000 mules on farms, an increase of 1,276,000 horses and 785,000 mules in the last decade. In addition to this, we exported in the nine-year period ended June 30, 1919, 1,149,763 horses and 376,836 mules.

**Growth of American Shipping.**—On June 30, 1920, the close of the fiscal year, the shipping registered, enrolled or licensed under the American flag, according to the official returns of the Bureau of Navigation, Department of Commerce, comprised 28,150 vessels of 16,350,000 gross tons. Final returns of smaller vessels built, lost, or abandoned will change slightly these figures one way or the other, but probably not to the extent of 100 vessels and 12,000 gross tons. Since January 1, 1919, closely following the armistice, American shipping in round numbers has increased 5,000,000 gross tons, and during the fiscal year just ended the increase has been 3,400,000 gross tons, of which 3,100,000 gross tons are documented in the name of the Government, represented by the Shipping Board.

**Again, the Hydraulic Propeller.**—The principles of operation of the Hotchkiss hydraulic propeller are, briefly, the formation of a vortex in a drum or casing, by the rotation of an impeller, the vortex discharging tangentially to give the thrust, and being fed in the direction of rotation by two converging streams which meet immediately over the discharge stream. By rotation of the drum casing the discharge stream may be moved so as to flow through a reversing port, and thus maneuvering can be carried out independently of the direction of rotation of the engine. The drum casing is carried in an outer drum or casing containing the reversing port; a further movement of the control lever rotates the inner drum until both the inlet ports and the discharge cutting are masked by the outer casing. The propeller is, therefore, converted into a sealed drum, with neither inlets nor outlets, and since pumping ceases, all of the load other than frictional is taken off the engine, and a hydraulic clutch is the result.

## *Engineering*

**Fitting the Roof to the Factory.**—Too little attention is generally given to the roof of the factory by the architect, when, as a matter of fact, the roof is just as important as the floor plan. Indeed, there are several types of roof available today for factory purposes, and the plans of any factory should always take into consideration the type of roof best suited to the requirements.

**Making Money By Destruction.**—Owing to the high cost of building materials, about one-third of the materials from a house-wrecking operation may be used again for building purposes. Formerly the house wrecker's chief concern was to take down the construction in the least possible time and at the least expense to himself; but today he also figures on ways and means of removing said construction with such care as to secure much valuable building material. It is well within the memory of most of us when salvaged bricks sold for $1.00 a load with 2,000 bricks to a load. Today salvaged bricks bring $10.00 and in some instances as high as $15.00 a thousand.

**Sea Bathing in Paris,** which, as everyone knows, is an inland city, is soon to be realized. Water from the sea is to be conveyed to the French capital by a long pipe line which has been planned by M. Alvarez of the Department of Roads and Bridges, as corollary to the scheme for bringing "mazout" or heavy oils from Havre to Paris by means of pipe lines three feet in diameter. Two such pipe lines are to be built, and a third line is planned for conveying sea water to a huge reservoir near Paris, where tired workers might rebuild their vigor and health over Sunday. The great cost of the pumping installation has stood in the way of the project, but it has now been suggested that the pumps be reversed during winter months for the purpose of pumping water from the Seine to the sea, in this manner reducing the danger of floods.

**Points on Roads.**—As loads are transmitted from the wearing course to the foundation and from there distributed to the subgrade, the bearing power of the soil composing the subgrade is an important factor in the design of the highway. It is well known that the bearing power of soils in many instances is materially increased by efficient drainage. The roadway, therefore, should be drained so that the maximum wearing power of the subgrade is developed, according to A. H. Blanchard, S.A.E. While a poorly drained roadway might support a light rural traffic, it will be rapidly destroyed if subjected to commercial motor transport including, for example, several five-ton trucks. The greatest improvement noted in American foundation practice is the use of cement-concrete foundations, or stone foundations of equivalent strength, on State trunk highway systems.

**Organic Impurities and Concrete.**—Tests made in the Structural Materials Research Laboratory with the coöperation of Lewis Institute and the Portland Cement Association show that the long recognized injurious effect on concrete of organic ingredients is a fact. The following conclusions were reached: The strength of concrete was reduced for all percentages of tannic acid, for all mixes and ages covered by these tests. Less than 0.01 per cent of tannic acid in terms of the weight of the aggregate may reduce the strength of the concrete to one-half its normal value. Lean mixtures are more affected by tannic acid than rich ones. The mixtures from the finer aggregates are less affected by tannic acid than those from the coarser aggregates. All of the effects mentioned may be summed up by saying that the reduction in strength of concrete is a function of the concentration of tannic acid in the mixing water.

**What Makes Rails Wear Out?**—It is pointed out by an authority that the ordinary car traffic is not entirely responsible for rail wear. The constant traffic of ordinary road vehicles has a considerable wearing influence. In a general way rail wear is dependent on the operating speed of the car, weight of equipment, density of traffic, use of brakes, frequency of stops, grades, alinement with respect to curvature, design of rails, design of wheels, upkeep of wheels, use of sand, cleanliness of streets, and manufacture and composition of the rails. Curves prepared by this authority indicate that a traffic of 216,000 cars at a speed of 18 miles per hour produced in three years the same wear as a traffic of 320,000 cars at a speed of 9 miles per hour in four years. In a single-track line the wear is seldom greater, and is frequently less, than in a double-track line: an apparent paradox which is probably explained by the reversal of direction of traffic, which tends to neutralize cold-rolling actions in the surface of the rail-head.

## *Industrial Progress*

**Belgium's Diamond Industry.**—The number of union workers in the diamond industry in Belgium reported to be out of work is 6,500 out of a total of 12,000. Owing to a falling off of the demand for cut stones, employers are seeking to decrease wages 35 per cent. The diamond workers' union has objected to this, and is unwilling to accept a diminution of more than 15 per cent. The matter is being arbitrated. In the meantime hundreds of employes are seeking other work.

**Italy's Mining Industry.**—Among the Italian industries which progressed most during the war was the mining industry. In 1914 it comprised 1,062 mines, employed 46,412 workmen, and the output was valued at 96,500,000 lire. As regards amount of mineral extracted, the sulfur industry came first with 2,371,705 tons of ore, followed by coal and lignite, with 781,358 tons of product; iron ore, with 706,246 tons of product; iron pyrites, with 335,531 tons; and asphalt, zinc and mercury. Since 1914 Italian mining activity has been directed with more or less success toward the following ores: Iron, manganese, copper, lead, zinc, gold, antimony, mercury, tin and mixed ores; also toward iron pyrites, anthracite and lignite, ichthyolitic and bituminous schists, sulfur, rock salt, salts from springs, petroleum, carburetted hydrogen gas, mineral waters, asphaltic and bituminous rock, raw bitumen, aluminite, boric acid, and graphite.

**Spitzbergen's Natural Wealth** is again brought to our attention by the *Times Trade Supplement*. It is said that a totally new and, until the last few years, quite unsuspected source of fuel oil exists in Spitzbergen. The existence of oil-bearing shales in this far-off land has been known for some years. It is not

generally known, however, that a discovery of much greater portent than the existence of shale was made there last year. Samples of gas which bubbled to the surface of muddy pools have, on analysis, proved to contain an exceedingly high percentage of petroleum elements. Arrangements have been made by the owners of the territory thoroughly to prospect the region at once. There is great scope for industrial development in the islands, for, continues the *Times*, though only a small portion of their area has so far been prospected, during the past few years they have been proved to contain much mineral wealth.

**Cologne's Permanent Exposition.**—Cologne is planning to inaugurate a permanent exhibition, known as "Musterschau," mainly for raw material and half-manufactured goods. It is intended that special exhibitions will be held periodically. For the use of the exhibition two large halls of iron construction, 4,000 and 7,000 square meters, respectively, are already in the course of erection, to which smaller buildings will be added according to requirements.

**Italy's Floating Sample Fair.**—The success of the sample fair held both at Milan and at Padua seems to have been sufficient to stimulate further interest in this plan of developing sales. It is claimed that at the Milan fair actual orders amounting to 500,000,000 lire were taken. Figures for the Padua fair are not yet available. The latest project of this kind is that of a floating fair on board the steamship "Trinacria," which will cover the principal cities of the Western Mediterranean in the interests of Italian manufacturers. The length of the stay in each port will vary in accordance with its importance, from four to seven days. The cost to exhibitors will be 5,000 lire, in which all expenses are included.

**Signing Foreign Correspondence.**—Those who are familiar with commercial practices abroad understand that all correspondence addressed to foreign business houses should be signed by some one in authority—a member of the firm in the case of a partnership, or an officer of the company, or at least the export manager in the case of a corporation. It appears, however, that there are many American firms who use a rubber stamp, or the signing is done by some clerk occupying no position of authority. In a number of cases this has been unfavorably commented upon by European business men, who, quite naturally, wish to deal directly with the principals, and to be assured that the firms with which they are dealing are prepared to stand by the statements made in their letters.

## *Automotive Progress*

**Wood Disk Wheel.**—An automobile disk wheel made of wood has recently made its appearance after a series of tests both on the road and in the laboratory, according to *Automotive Industries*. The construction, which resembles in appearance the steel disk wheel, is of thin, rotary cut slices of wood, glued together under heavy pressure. The laminations are so built up that the grain of each piece runs in a different direction from that of the next piece, thus producing a result that is claimed by the makers to be strong, non-warpable, and thoroughly waterproof. Road shocks, it is declared, are distributed evenly.

**Steam Wagons.**—Europe, and England in particular, has long stood by the road locomotive which resembles nothing more than our steam road rollers. Now there is being developed in England a steam wagon which follows the general lines of the conventional gasoline truck. However, the steam power plant makes use of a regular boiler and firebox for coal. The framing of the wagon chassis is of pressed steel instead of the more usual channel iron, thus permitting of a lighter structure and one better proportioned to the stresses it has to carry. The final drive from the engine to the road wheels is by means of a pitch chain, as usual in vehicles of this type.

**French Automobile Manufacturers** are considering the United States as a market for their cars, according to a recent dispatch from Paris. Mr. Pierre Bassett, representative of the Syndicat Français des Constructeurs d'Automobiles, will leave France shortly to investigate conditions here and on the basis of his report will map out their sales campaign. Due to the French exchange situation and the low cost of freight space on ships returning to the United States, Mr. Bassett expects to place French trucks on sale here at prices which will compare favorably with local prices. Moreover, many of the large French concerns have developed considerable technique in fast construction. Their appeal will be directed toward customers in this country who are willing to pay the higher price for "something different."

**Magneto or Battery Ignition?**—Considerable interest has been expressed by engineers as to the relative power output of engines equipped with magneto and battery ignition, respectively. A test was recently made at McCook Field, Dayton, Ohio, for the purpose of comparing the results obtained with both types of ignition. A 180-horse-power Hispano-Suiza was equipped with a magneto for part of the test, and then with special battery ignition. The difference in performance was very slight. Practically the same power was obtained using either system. The gasoline consumption remained about the same in each case. However, as regards weight, the two magnetos, weighing 14½ pounds each, one starting magneto of six pounds and one switch of one pound, made a total of 32 pounds, while the battery ignition, calling for the motor units, distributors, breakers, coils, and so on weighed altogether 30 pounds, the ignition battery 10 pounds, the switch and regulator 2 pounds, giving a total of 42 pounds.

## *Communication*

**The Chinese Wireless Station** at the Temple of Heaven, Peking, is open for service. All the telegraph offices in the city are accepting radiograms at the same rates as those charged for land-line messages for transmission to Kalgan, Wuchang, Woosung, Shanghai, and Foochow. Special rates apply to radiograms sent to ship and aviation stations. This service gives Peking improved communication with some of the most important commercial centers in China.

**The Rome Wireless Station.**—It was in 1917 that the Italian Government planned the wireless station at Basilica of San Paolo, near Rome. It was decided on account of the necessity of rapid construction to use continuous waves, and for similar reasons the Poulsen arc system was adopted. The antenna chosen was one having the shape of an equilateral triangle supported by three cables more than 200 meters high, with down leads coming from one of the sides. The station is quite capable of receiving messages from American high power stations, but its transmitter does not maintain continuous touch with the American stations.

**Marconi's Wireless Telephone.**—In his recent experiments Marconi used a 15-kilowatt, 500-volt, 200-cycle generator supplying current to a 20,000-volt transformer, tapped at the secondary middle point. Two rectifying valves cause a condenser to be charged to half the total secondary voltage uni-directionally once every half-cycle, maintaining the condenser charge at about 10,000 volts for the supply of the transmitting and low frequency magnifying valves. To eliminate the distortion of the harmonics in the speech waves, and to obtain the best quality of speed it has been found that the best method is to absorb the energy in the aerial in accordance with the speech wave formed. This is effected by stepping up the microphone current to produce voltage curve similar in shape to that produced by the varying current caused by speech by means of a two-stage low frequency amplifier. The voltage variations are thus magnified and are impressed on the grids of the absorption valves. As is well known, the resistance of a three-electrode valve varies with the voltage impressed on the grid, so that in this case the conducting power of the absorption valve varies with the voltage curve produced by speech.

## *Electrical*

**Production of Electric Lamps.**—For the year 1919 sales of all kinds of lamps in the United States amounted to 183,000,000, and although this is 3,000,000 less than in 1918, the diminution is not substantial. An interesting feature is the diminution in the percentage of carbon filament lamps made. This has fallen from 11 per cent to 7 per cent in 1919. It is also interesting to note the increase in the use of gas-filled lamps, of which 24,000,000 were sold in 1918, as compared with 27,000,000 in 1919—a rise of 12½ per cent. Most interesting of all, no doubt, is the fact that the average candle power of lamps is steadily increasing.

**National Electrical Safety Code.**—The present edition of the *National Electrical Safety Code* was issued in 1916 for examination, trial and constructive criticism. It was realized that the code was not a perfected document and that experience should be obtained with it before the rules were made mandatory. War conditions delayed the expected trial, and although revision has been almost continuously under way, it was not until the present year that sufficient information and consideration of the rules could be obtained to warrant the publication of a new edition.

**Electro-Pneumatic Welding Machine.**—In operating spot-welding machines of the usual type the pressure required for the weld is produced by a foot pedal. This is tiring to the operator, especially as he may have to make 15,000 welds per day. The electro-pneumatic welding machines now being built in Germany are equipped with a compressed-air cylinder controlled by a foot pedal, which requires very small effort to depress. The motion may also be regulated by a small motor that actuates the mechanism a given number of times at the required intervals. By this device the capacity of the welding machine may be increased by 50 per cent.

**Electrification of Japan's Railroads.**—According to the provisions of the bill introduced in the Diet for the complete electrification of the railroads of Japan, the Government would invest 50,000,000 yen in a semi-governmental electric power company, which would be capitalized at 100,000,000 yen, the other half of the capital stock to be subscribed by Japanese citizens or bodies incorporated under the laws of Japan. It is further understood that the Japanese Government contemplates erecting the largest hydro-electric plant in Japan on the River Shinanogawa near Tokio, which would probably be supplemented by a large steam plant also near Tokio.

**Remotely Controlled Electric Locomotives.**—In a recent issue of the *Electric Journal* there appears an interesting account of a remotely controlled electric locomotive. The motorman first brings the locomotive with eight empty cars and spots the first car under the loading chutes at the screen station of the coke plant. The motorman then throws a switch and places the locomotive under the control of the operator in the screen station and leaves the locomotive. The operator then slowly moves the train forward, stopping or reversing it as conditions may require, thereby securing an evenly and completely loaded car. When the cars are loaded the motorman returns to the locomotive and draws the cars to the classification yards, returns for empty cars and the cycle is completed.

## *Chemical and Metallurgical*

**Alloyed Aluminum.**—Much progress has been made of late in the development of new aluminum alloys, especially for use in the automotive industry. The most sensational step, according to a leading authority on this subject, is the evolution of a forging alloy which promises to accomplish much in automobile engine design, in the way of cutting down the reciprocating weight and in reducing rotating masses and bearing pressures. The physical properties which have so far been secured in the forging alloy are said to be 55,000 to 65,000 pounds per square inch tensile strength, with 18 to 22 per cent elongation and 38 to 40 per cent reduction in area.

**Use of Manganese.**—Approximately 95 per cent of the manganese consumed in the United States is used in making steel not only to deoxidize and recarburize the molten metal, thereby making possible the production of cleaner and sounder ingots containing the desired amount of carbon, but also to impart certain qualities to the finished product. Small proportions of manganese, 0.5 to 0.8 per cent, make the steel easier to work and stronger in service. At the same time slight proportions of impurities remaining in the steel are taken into combination and rendered less harmful. Relatively small quantities of so-called "manganese" steel are made which contain 11 to 14 per cent or more of manganese and possess special qualities of hardness and strength.

**Electrolytic Purification of Clays.**—The electrolysis of colloidal solutions has led to the application of this principle to the purification of china and other clays. If clay is mixed with water and certain alkalis are then added to the solution, the mixture settles and becomes more liquid. If, now, an electric current is passed through the solution, the particles of clay connect at the anode, while the impurities (mica, felspar, quartz, iron compounds) either are precipitated or migrate to the cathode. On an industrial scale the process is carried out in a large vat, in which slowly rotates a metal cylinder forming the anode, and near which the cathode is placed, continues *L'Industria*. The clay paste, after the electrolyte is added, is left to clarify in other tanks, being then passed into the electrolyzing vat for final purification, when it is collected by special rakes. In addition to being pure, clay thus treated has a lower temperature of agglomeration, molds more easily, and is more plastic and refractory.

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*

**Speaking into this telephone, the guard projects his voice through several loud-speaking telephones**

## An Electrified Voice for the Subway Guard

RELIEF from the inarticulate sounds emanating from the guards in announcing subway stations is in sight. It is to come in the form of a loud-speaking telephone developed by E. E. Trafton, telephone engineer of the Brooklyn Rapid Transit system of Brooklyn, N. Y.

It is claimed that the operation of the new loud-speaking telephone entails little effort on the part of the guard, who speaks in an ordinary voice through a transmitter located at the central panel which contains the push-buttons controlling the doors of the car. Loud-speaking units are installed on the ceilings of the car, so that the voice of the guard is greatly amplified and distributed throughout the car. The transmitter, into which the guard speaks, is provided with a button for throwing it in and out of circuit, as well as a peculiarly-shaped mouth piece with four petals instead of the usual cone shape.

## Speeding Up the French Fried Potatoes

THOSE French fried potatoes which many of us ordered when porterhouse steak was within the reach of us all, are not easily prepared unless some special device is used for the cutting. Here is one that has been invented recently and that seems to put speed into the preparation of this much favored item of the menu card. Mounted on the top of a nickel plated hollow base is a square surface across which numerous cutting blades are strung. By pushing the potato through the cutting squares they fall below ready to be cooked.

**Pushing the potato down on this device paves the way for French fried potatoes**

## For Handling the Camper's Baked Potatoes

THOSE of you who are camping or who are planning a trip out into the great out-of-doors in the future will find this newly-designed cooking utensil useful. It is called a pusher fork. By manipulating the spring handle, corn or hot baked potatoes can be picked up and served on a plate without burning the fingers. Our illustration shows the potato being pushed from the fork. By releasing the thumb on the spring handle the small "pusher," which slips along the tines to the end, will fall back into position near the point where the tines join. The "pusher" cannot go beyond the end of the tines.

**There need be no burnt fingers when handling potatoes with this pusher fork**

## More Heat from Less Coal

THE older houses and apartments in the Malmo section of Sweden are provided with very simple cast-iron cooking stoves. The newer buildings, however, are equipped with gas cooking apparatus almost exclusively. Gas is available in nearly all cities in southern Sweden, and is more generally used for cooking than for light. Buildings constructed more than 10 years ago have few furnaces, but are heated by high tiled stoves, which are characteristic of all Scandinavian countries. These tiled stoves can be opened so as to produce a fire-place effect. The new houses, villas, and apartments are provided with furnaces burning coal or coke. Hot-water heaters are more frequently found than any other kind. The coils and radiators are quite modern in design and compare favorably with those in use in other progressive European countries.

Most of the heating and cooking apparatus is produced locally in the industrial region of central Sweden. The principal imports before the war came from Germany. The Germans shipped more gas cooking stoves to southern Sweden than other kinds. The German stoves are more modern than those produced in Sweden. Imports from other countries were small.

## Agricultural Exposition to Be Held in Belgium

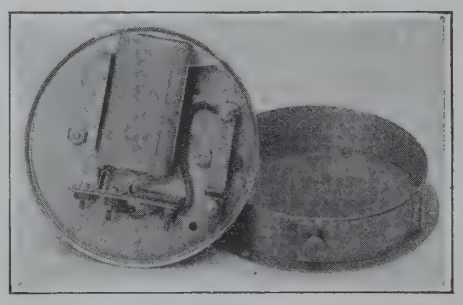
THE legation of Belgium at Washington has announced that an exposition of agriculture and agricultural husbandry will be organized at Laken-Brussels in September, 1920, under the patronage of the Ministry of Agriculture of Belgium. The object of the undertaking is to bring together the implements most useful to agriculture—machinery, furniture, experimentation, and instruction.

The Minister of Agriculture of Belgium has expressed a wish that the exposition be made known to the industrial and scientific special centers which in the United States are most interested in the furniture, apparatus, and implements, and also the methods and arrangements by which labor can be saved on the farm and in the rural household.

Firms interested in an exposition of this kind can communicate with Mr. De Vuyst, Director General of the Ministry of Agriculture, Place Quételet, at Brussels, with a view to sending to the exposition all novelties and specialties that come under the head as above outlined. Exhibits which the owners would be willing to leave to the superior normal institute of agricultural husbandry after the exposition would be used in the museum that would be periodically opened to the public.

## Bringing Buzzer and Battery Together

A NEW design of electric buzzer has appeared that does not require a dry cell outside of the bell itself. The buzzer uses a flash-light battery which is concealed within the casing of the bell. It is so made that it can be operated at some distance or by using the push buttons installed on the buzzers. The binding posts on the right and left of the push button can have proper wire connections for some outside use of the buzzer. In the bottom of the metal case, upon which the bell is mounted, is a small door. By opening this a worn flash-light battery can be removed and another pushed into its place. The coils of the electromagnets are wound for about 8.5 ohm. where a 2-cell battery is employed. Buzzers are all made for the 2-cell battery, with a 2½ gong.

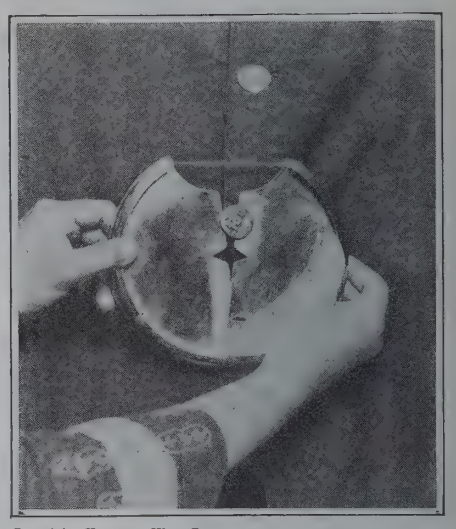


**This buzzer is entirely a self-contained unit, having its own battery**

## Polishing Brass Buttons Without Spotting the Uniform

IT has come to be a popular belief that women are not inventive. Yet time and again we find some ingenious idea conceived by a woman; and the truth of the matter seems to be that women, unlike men, do not invent unless they are driven to it, so to speak. In other words, women will invent through sheer necessity.

Such is the case with Mrs. Hannah Schachne of New York City, the wife of a policeman, who has invented a new and less tedious method of cleaning buttons on all uniforms. Mrs. Schachne has been cleaning her husband's brass buttons for years and great care has had to be exercised not to spoil or ruin the cloth around the buttons. So in her search for a better way to do this work, she invented the simple shield shown in the accompanying illustration. The action of the shield is self-explanatory.



Copyright, Keystone View Co.

**This simple shield protects the uniform while the buttons are being polished**

## A New Partnership: Phonograph and Alarm Clock

IT may be that the war has something to do with it; so many of our young men have learned to get up in the morning to the tune of the "Reveille" that it is hard to get along with the more conventional alarm clock. At any rate, Oscar Lindholm, a machinist of Chicago, Ill., has invented the alarm clock-phonograph, shown in the accompanying illustration. In this device use is made of a standard alarm clock for the purpose of starting the turntable of a standard phonograph. The clock can be set for any desired time. When the clock "goes off" it starts the turntable of the phonograph. In this manner it is possible to vary one's rising call. One day it may be a good cornet solo; again it may be a popular song of the moment; still again, it may be a crashing military march. Or if one desires a personal tone in the summons to arise, it may be a man's or woman's voice. At any rate, the phonograph has another useful mission to perform.

**The alarm clock starts the phonograph which plays any desired music to get one out of bed**

# FAIRBANKS-MORSE

## Dependable service has established "Z" engine dominance

The American farmer today is using more than two hundred and fifty thousand Fairbanks-Morse "Z" engines.

He lights his home with the electricity it provides, operates with it his separator, churn, feed-grinder and ensilage cutter. His sprayer is likely to be powered with a "Z" engine. In the South it loads his sugar cane and performs a host of other labor-saving tasks.

The ease with which the "Z" does these farm chores has created for it also a widespread demand for industrial uses.

In the machine shop, the mill and the printing office, "Z" engines are delivering consistent day-by-day service. Out in the open they are pumping water, operating concrete mixers and furnishing power for hoists and other construction machinery.

The successful service of the "Z" engine in agriculture and industry is another step toward the goal reflected in the Fairbanks-Morse Quality Mark.

Our products include Fairbanks Scales—oil engines—pumps—electric motors and generators—railway appliances and coaling stations—farm power machinery, such as "Z" engines, lighting plants, water systems.

# Stale Air Out Fresh Air In

YOU can't get fresh air **in** unless you get stale air **out.**

Generally the stale air rises at first, because it's warmer than the fresh outside air. Give it free exit near the ceiling, at the same time opening inlets near the floor, and the stale air slips quietly out while fresh air takes its place.

But if the stale air is kept indooors it presently cools, descends, and mixes with the lower air. Thereafter the stale air cannot be separated from the fresh air unless there is a wind blowing across.

With properly-placed **upper and lower** ventilators, even a wide building will have fresh air. But how many buildings do you see that have only one row of ventilators, located about midway of the sash height? Such a building cannot be adequately ventilated without a cross wind.

The building here shown is an example of good design, using Lupton Pivoted Factory Sash with connected upper and lower ventilators. We are always glad to advise intending builders regarding the best choice and arrangement of sash for their special needs.

We have published an interesting booklet, "Air, Light and Efficiency." It's free on request.

## New York's Radio Pilot Cable

(*Continued from page 195*)

breaking the cable current in order to transmit signals; in fact, an automatic sending apparatus may be installed so as to send out given signals over and over again when necessary.

So much for the cable. Now the receiving end aboard ship is quite as simple. Two coils are required, each four feet square and wound with 400 turns of No. 24 S.C.C. copper magnet wire. Care should be exercised in making these coils so that each coil will have the same resistance and inductance values. Much depends upon this precaution as the signal strength received by each coil is the function of the resistance of each coil, and should their resistance be different, a signal strength of different intensity will be received by each coil when at the same distance from the cable. The best shape for the coils is the pancake. The wire can be wound in pancake form four feet square, with a winding space of one inch. The coils are impregnated in paraffin and then placed in wooden boxes with more paraffin in order to protect them from abrasion.

The coils should be placed over the side of the ship approximately amidship, one coil on one side and the other coil on the opposite side, below the surface of the water or slightly above the water line.

## Gas Engine Versus Steam Engine

(*Continued from page 197*)

tion by means of these two modern vehicles, which, coupled with the good-roads movement in California, are re-forming the whole social and industrial world.

California is one of the foremost States in the Union in the voting of bonds for the construction of good roads. The work was begun in 1909 when the State Highway Appropriation Act provided for a State bond issue of $18,000,000 for the construction of highways. The work of construction was begun as soon as this fund was available. But the enterprise loomed so large, as the work went on, that the fund provided appeared entirely inadequate. Accordingly on November 7th, 1916, another bond issue of $15,000,000 was voted by the State to further prosecute the work of good road building. Then there came an actual craze for good roads in California, and eventually a special election was held and a third bond issue of $40,000,000 authorized.

This building of good roads has only stimulated the use of the public motor truck and auto stage. "Ship-by-truck" has become a popular slogan in California, and the truck and tire interests are boosting the movement with the greatest spirit and vigor.

The problem of the short haul by truck appears to be working out automatically and to be far on the road to solution. The truck as an individual carrier has asserted itself, and nothing appears to threaten its permanency. The truck as a common carrier is still in its experimental stage. But the thing has such great promise, is the subject of so much enthusiastic effort and is surrounded by so much freedom of action that it seems to have a brilliant future.

## A Neat Problem in Hydraulics

(*Continued from page 198*)

walls of steel sheeting at intervals of, say, 300 or 400 feet. The piling was one of the standard forms of rolled sheeting. That is, each pile is a single "plank" of steel without rivets or bolts. The edges are given such forms as to enable each pile to interlock with its companions on the two sides. There are several such varieties of steel sheet piling in use. They are American triumphs in the art of rolling steel. When assembled, the particular size of piling here used provides a covering 14 inches wide per pile.

# *The Men who Distribute the new Leland-built Lincoln Car*

Those who know motor cars, know that high character and soundness in the organizations which produce them, should be paralleled by like character and soundness in the organizations which distribute them—the men who form the connecting links or points of contact between the car owner and the manufacturer.

The distributing organizations of the Lincoln Motor Co. are in fifteen cities, including a factory sales branch in Detroit.

As production increases, additional distributors will be selected from the nearly 2,000 applicants already in waiting. Many of these, even now, have lists of priority orders and orders conditional upon their appointment.

In the fourteen cities where sales franchises have been granted, selections were made from among 416 applicants.

In not one single instance was it a matter of soliciting a distributor, nor of accepting whomsoever could be obtained. In every case it was one of our own choosing—of selecting those who we believed to measure up to the standards we had established, and whose high standing in their respective cities had been abundantly tested.

Nor was this a simple procedure, because most of the applicants were distributors well established, of high repute, and already handling cars of the better class. They were men who have made it their business to know motor cars and motor car builders.

With this type of applicants it was a matter of carefully choosing those best qualified.

LELAND-BUILT
LINCOLN

Most of them have had sales franchises continually thrust upon them for consideration, and could obtain almost any franchise merely for the asking.

We have selected organizations and men accustomed to contact with the highest type of citizens —the class to whom the Leland-built Lincoln car will naturally appeal.

They are men cognizant of their responsibilities; men who are not unmindful that upon delivery of a car to the purchaser, their duty has just begun.

These men have shown the faith that is in them by cooly and deliberately obligating themselves to merchandise millions of dollars worth of motor cars—cars of whose features, and details, and price they were wholly without information.

And their faith is further evinced, in most of the cities, by the erection of modern and adequate structures, quite in keeping with the product and with the clientele.

Their faith in the car, and in the organization which produces it, is confirmed by the faith of more than one thousand of the best citizens who, likewise without definite knowledge of the car, its features, its details, or its price, insisted upon filing priority orders—without encouragement from the factory, and seldom with encouragement from the distributor.

Their faith too, is not without judgment. They know the organization behind the car. They know the character and the accomplishments of the men behind that organization; they know their works and their record; they know their ideals in motor car engineering and motor car construction; they know their forward vision.

Above all, they know the Leland determination and Leland ability to achieve—and to surpass.

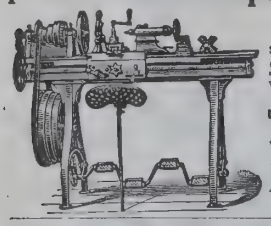
TEMPERATURE INSTRUMENTS
INDICATING • RECORDING • CONTROLLING

SPECIALIZATION

WE have continuously striven toward one objective: the solution of temperature problems. Today there are *Tycos* Temperature Instruments — Indicating, Recording, Controlling—for every industry. And each instrument fits a specific need.
We have proven apt in solving individual temperature problems. Let us assist you.
*Taylor Instrument Companies*
Rochester, N.Y.
*There's a Tycos or Taylor Thermometer for Every Purpose*

We Will Make It
Anything in a metal stamping or novelty produced from any metal and finished in any color.
Waterbury Button Co., Waterbury, Conn.

For Gunsmiths, Tool Makers, Experimental & Repair Work, etc.



From 9-in. to 18-in. swing. Arranged for Steam or Foot Power, Velocipede or Stand-up Treadle.
W. F. & J. Barnes Co.
Established 1872.
1999 Ruby Street
Rockford, Ill.

UNISOL BOILER PRESERVER
Warranted without reserve, to remove boiler scale, prevent pitting and scale formation.
Pamphlet on request. Money back guarantee.
UNISOL-MFG. CO. Jersey City, N. J.

ASBESTOS

We are miners and shippers of Crude Asbestos in any quantity. We produce all grades at our world famous BELL ASBESTOS MINES in Canada. We also carry Abres, spin yarns, weave cloths, and make all sorts of fisbestos products.

## A Neat Problem in Hydraulics

(*Continued from page 210*)

Naturally, the actual width of each pile is something in excess. Altogether, the number of lineal feet of piling used for this dock amounts to nearly 75,000. The weight of steel was some 3,100,000 pounds.

It will be remembered perhaps that it was pointed out that strata of hard white sand and cemented gravel overlie the red clay. The driving of the piles through these layers proved very difficult indeed. Some of the piles went down very well; but a large percentage of the total resisted strenuously the efforts of the pile driver. The piling was heavy and strong, weighing about 41 pounds per lineal foot; and yet much of it was later on found to have suffered a good deal from bending and tearing apart. Steel sheeting is ordinarily driven by blows delivered upon its head, usually through an interposed cap. Its stiffness, strength and edge thinness are relied on to secure penetration. As a rule, the pile goes down, cutting its way through the soil and even through buried trees and old lumber. But, here at the Navy Yard, not only was there the combination of the two difficult strata already mentioned, but also big boulders would at times be encountered. Under the almost resistless drive of the pile driver, the steel pile would at times be diverted by a boulder and curl up as if it were a wooden shaving made by a hand plane.

The dock is an enormous box of concrete, and a representative cross-section is not unlike a similar section of a lock. There is the heavy floor of concrete, and the massive side walls of the same material. At Panama the pouring of concrete in the locks was a problem that received more than one solution. At Gatun, the concrete on the very side was handled by cableways stretched transversely across the locks between movable towers shifting lengthwise the site. On the Pacific side, berm cranes serving towers on the center line were employed in at least two pairs of locks. Here in Philadelphia a giant crane not dissimilar to those used with ordinary locomotive crane units was mounted upon a wide-gaged track laid lengthwise of the dock on the one side. One pair of rails was laid on top of the side wall and the other on a concrete stringer supported by bents of bearing piles. This was the arrangement on the west side where the summit of the wall is narrow. On the east side the wall is quite broad. The great boom had a maximum reach of nearly 130 feet at which radius a load of 15 tons could be handled. At a radius of 92½ feet 50 gross tons was a possible load.

## What Has Been Said About Einstein

(*Continued from page 200*)

new and startling when put before us so bluntly as they have been since last December.

He might be a little clearer on some points—notably with regard to the circumstance that the element with which the four-dimensional manifold of space-time is concerned is not the "thing" as he so often has it, but rather the "event." But we would not be understood as criticizing Dr. Slosson's book too severely. It would be extraordinary if no suspicion of technical error were to be found in a discussion so completely and successfully toned down to the popular level. Of its kind this discussion is admirable, and its style is inimitable beyond all adverbial qualification. Our one regret after reading it is that we passed through the mill of Columbia too early to have attended Dr. Slosson's lectures. If he can talk as he writes he must have constant need of a "Standing Room Only" sign such as Dr. Eddington may be pictured as employing when the line of Cambridge students waiting to get into the hall where he was to lecture on Einstein mussed up the entire college grounds. And we may return to the Eddington volume right here to recommend the reading of the delightful three-cornered Socratic conversation between the physicist, the relativist and the mathematician, with which it opens, as an admirable prolog or epilog to the Slosson book.

Other books which have appeared in English for popular or semi-popular consumption might seem to call for attention here. But the fact is we can say nothing good of any of these, and in charity to the publishers who have trustingly supplied us with copies for review it seems unnecessary to say anything bad about any specific one of them. They may reasonably go by default, so far as this review is concerned, hiding their all-too-meager lights under a bushel. A word about magazine articles, however, may not be out of place here. Again it is to be understood that we make no effort to catalog everything that has been published, mentioning only those whose reading seems profitable in connection either with the preparation of an essay for this contest or with the preparation for reading such of these essays as may be published.

Dr. Eddington's article on Einstein in the *Contemporary Review* for December, 1919, is the best that has appeared in English, in our regard. It is fully covered by his book, however, so that one would not care to read the article after having perused or before perusing the book. His article on gravitation in the SCIENTIFIC AMERICAN SUPPLEMENT of July 6th and 13th, 1918, is perhaps a little more out of the track of subsequent discussions, and might well be read by a student of the Einstein doctrines. Of American articles, we prefer those by Dr. Stewart in our own columns under date of January 3rd last, by Mr. Lotka in *Harper's Magazine* for one of the spring months of 1920—the exigencies of going to press do not permit of exact determination of the date—and by Professor Cohen in the *New Republic*. The last named treatment is of value in that it emphasizes as we have seen emphasized in no other place the fact that the present accepted body of Einstein theory is really a composite of three independently promulgated researches—the first and the second, or the restricted and the generalized principles of relativity, and the theory of gravitation. As Professor Cohen says, a great deal of misunderstanding has been created through the overlooking of this circumstance in popular articles by semi-competent writers. But Professor Cohen himself transgresses rather seriously when he comes to discuss the geometric character of the space-time manifold, for he here states as an uncontroverted fact several conclusions on which Dr. Eddington himself was at last accounts not yet ready to express a final opinion.

Einstein himself is responsible for two articles which have been translated from the German in which he wrote them for popular consumption, and which have appeared quite generally in English These are not intelligible to a layman and not of any significance to an informed mathematician. It would appear that the great man is not at home when he tries to stoop to the level of common folk—a common enough phenomenon and one which should never be surprising.

## Fire Without Firemen

(*Continued from page 202*)

such installations that a steady fire, readily under control, be available. With hand firing of coal this would be impossible and fuel oil or gas would have to be used at greater cost.

Just as important as the stoker is the machinery for bringing the coal to the furnace and removing the ashes. At first thought it would seem that this is a simple conveyor problem that might easily be solved in any one of a number of ways. And so it is, in the case of the coal. In many of the large power houses the coal is fed from huge hoppers over the boilers, into which the coal is dumped directly from the cars. Or any one of the standard conveyor systems will prove satisfactory if conditions do not permit the simpler arrangement.

But ash handling presents a more difficult problem for solution. It was once a common practice to use the same conveyor system for both coal and ash but in practically all of the important installations now separate or "divorced" systems are used.

This is because the ashes are never "plain ashes." They are either dripping wet, red-hot, dry and dusty or full of big clinkers. If the ashes are handled wet they pack in conveyor cars and cake there. If they are handled dry a system must be used that will not spread the dust to all parts of the plant. The equipment must be heavy enough to withstand warping from the heat; there must be no exposed bearing or joints to be cut out by the abrasive action of the ash; and above all the conveyor must not consume too much power. In addition there is a safety problem for enclosed ash dust occasionally explodes with disastrous results. The severe conditions which ash conveyors must overcome may be realized from the fact that while the depreciation in ordinary conveying machinery is usually figured at 10 per cent, the depreciation for ash conveyors often is as high as 30 or 40 per cent.

There are six general schemes of ash conveying in general use, each best suited to a peculiar set of conditions. The machine handling of fuel from the car to the ash pile has introduced a multiplicity of problems that must be carefully considered before an installation is made. And so, along with the stoker and conveyor has grown a new profession—that of combustion engineer. Every important boiler plant is now designed by a combustion engineer to fit the peculiar conditions present. He considers the space available, value of the land, the kind of fuel available, boiler capacity, expected overloads, etc. The well-designed plant is a harmonious unit, through which the fuel passes without the expenditure of any manual labor and only the supervision of one or two trained men.

The result is not nearly so picturesque as the glaring furnace door and the half-stripped stoker, but it is much more efficient.

## Wood That Is Stronger Than Steel

(*Continued from page 204*)

by the laboratory experts; one made from the blood of animals and one derived from casein—obtained from milk. Panels were glued together with these and tested in boiling water for eight hours. At the expiration of this time none of the pieces showed any separation of the plies. Soaking in cold water for ten days gave the same results. Finally, tests with a shearing machine, which applied force in such manner as to push one ply from another, were made, and it was demonstrated that a pressure of from two hundred and fifty to seven hundred pounds to the square inch of glue surface was required to separate the layers, so strong were the new glues. As a matter of fact, it was, in most cases, not the glue, but the wood fibers themselves, that gave way.

In considering the application of this new water-proof glue and plywood to industry in our reconstruction period, it becomes evident that an entirely new field has opened for progressive manufacturers of wood articles. Who, till now, has put on the market a standard door that will not warp? Plywood panels cannot warp after they are finished, for one ply holds the next rigidly. What manufacturer has got out a table or chair with glued joints that will not fall to pieces in a damp atmosphere? Furniture made with casein glue will hold together far better.

# FIRST *in* Construction Hauling

IN the whole field of truck operation there is no more drastic demand upon power, efficiency and endurance than in hauling crushed stone, sand, brick, cement, lumber, structural steel and machinery.

Tons of material are literally dumped into the trucks from buckets, chutes or derricks. These loads are carried over torn-up ground, into and out of excavations, to places where the trucks must break their own path. Materials must be kept moving. Deliveries are vital. Trucks work day and night.

For years White Trucks have had a predominant position in this field. They are the mainstay of contractors, of road and bridge builders, of dealers in lumber and building supplies.

They not only stand up and keep going day in and day out, year after year; they pay dividends long after the investment is written off the books. White Trucks are distinctly a balance sheet proposition; their earning power is *sustained.*

White Trucks are used by contractors in 156 cities. They are used by 431 lumber dealers; by 218 dealers in building supplies and by 224 miscellaneous concerns in the building and contracting field; 365 states, counties and municipalities use White Trucks on road construction and maintenance work.

These owners know from their cost records that White Trucks not only do the *most* work, but they do it for the *least* money.

THE WHITE COMPANY, *Cleveland*

# WHITE TRUCKS

# *A fire department you never heard of*

HERE it is—posing for its picture. No clanging bells or shrieking sirens. No red lined coats. Nothing spectacular.

Just a few skilled workmen—yet these men save the ladder and the engine crews many a trip by making roofs fire-safe with Asbestos. For the time to put out fires is before they start. And there is no better way to prevent roof communicated fires than by covering roofs with Asbestos.

Moreover, it is not only through fire protection that Asbestos makes roofs safe, but also through weatherproof durability. In fact, Asbestos seems ordained by nature to be a roofing material. This wonderful fibrous mineral is not only absolutely fire-proof, but in roofing form it is immune to the disintegrating effects of sun, snow, hail, ice, rain, smoke and acid fumes.

On the big flat roofs of industrial plants and other buildings you will find Johns-Manville roofers applying permanent fire prevention with Johns-Manville Asbestos Roofing.*

And on thousands of smaller buildings the owners themselves, or their employees, are doing the same. For the many different types of Johns-Manville Asbestos Roofing give everyone the opportunity to protect what is ordinarily the most defenseless part of his building—the roof—with one of these roofings.

*Asbestos Roll Roofing, Johns-Manville Standard and Colorblende Asbestos Shingles, Johns-Manville Asbestos Ready Roofing, Johns-Manville Corrugated Asbestos Roofing, Johns-Manville Built-Up Asbestos Roofings.*

*Johns-Manville Asbestos Roofings are approved by the Underwriters' Laboratories, Inc.*

*All Johns-Manville Asbestos Roofing is backed by Johns-Manville Service and Responsibility. Through our Roofing Registration Service we are able to keep in touch with Johns-Manville Roofing in Service. This is your assurance that it will give the service claimed for it.*

# What makes engineering authority

VISIT the busy freight receiving platform of any railroad. Of the score or more motor trucks loading, there will be half a dozen assorted sizes doing practically the same work.

Why so many sizes for the same job? Which size is *right*? Who said so?

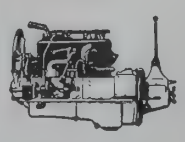
* * *

The business man can select his motor trucks either of two ways. He can trust to rule of thumb "commercial practice." Taking it for granted that the truck is right—that its parts are what they ought to be—and that his "saving" in first cost is a genuine economy.

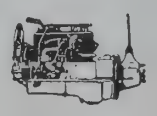
Or he can go straight to the truck vouched for by *engineering authority*. Designed for the work it has to do. Each part designed in relation to every other part—and built under rigid supervision. *Sure saving in cost of transportation.*

In all industrial America there is no higher example of engineering carried intensively into a product than the Packard Truck.

The 44 definite factors of superiority in the Packard Truck are the direct outcome of Packard intensive engineering.



Each size of Packard Truck designed for a specific transportation need.



Each size designed as a unit around its *engine* as a basis.

Rear-end, clutch, gears—each size the proper design for its own engine.

Packard unity of design overcoming that common difficulty—an engine too big for the rear-end, or driving mechanism too heavy for the engine.

One reason why Packard Trucks handle greater loads economically per hundred pounds of truck.

The design of the Truck—and of its parts. The selection of material. The new and advanced processes developed. Special machine equipment invented.

Packard standards in the finished truck ensured by holding one inspector responsible for the work of each twenty men throughout the Packard plant.

All leading up to the unequalled strength of the Packard truck parts and the high performance of the Packard Truck.

Packard engineering puts *economy on the road* ahead of cheapening production in the factory.

Low transportation costs shown by Packard Trucks—dependable performance—long life—all matters of record.

Records and the "44 factors" available to business men at local Packard headquarters.

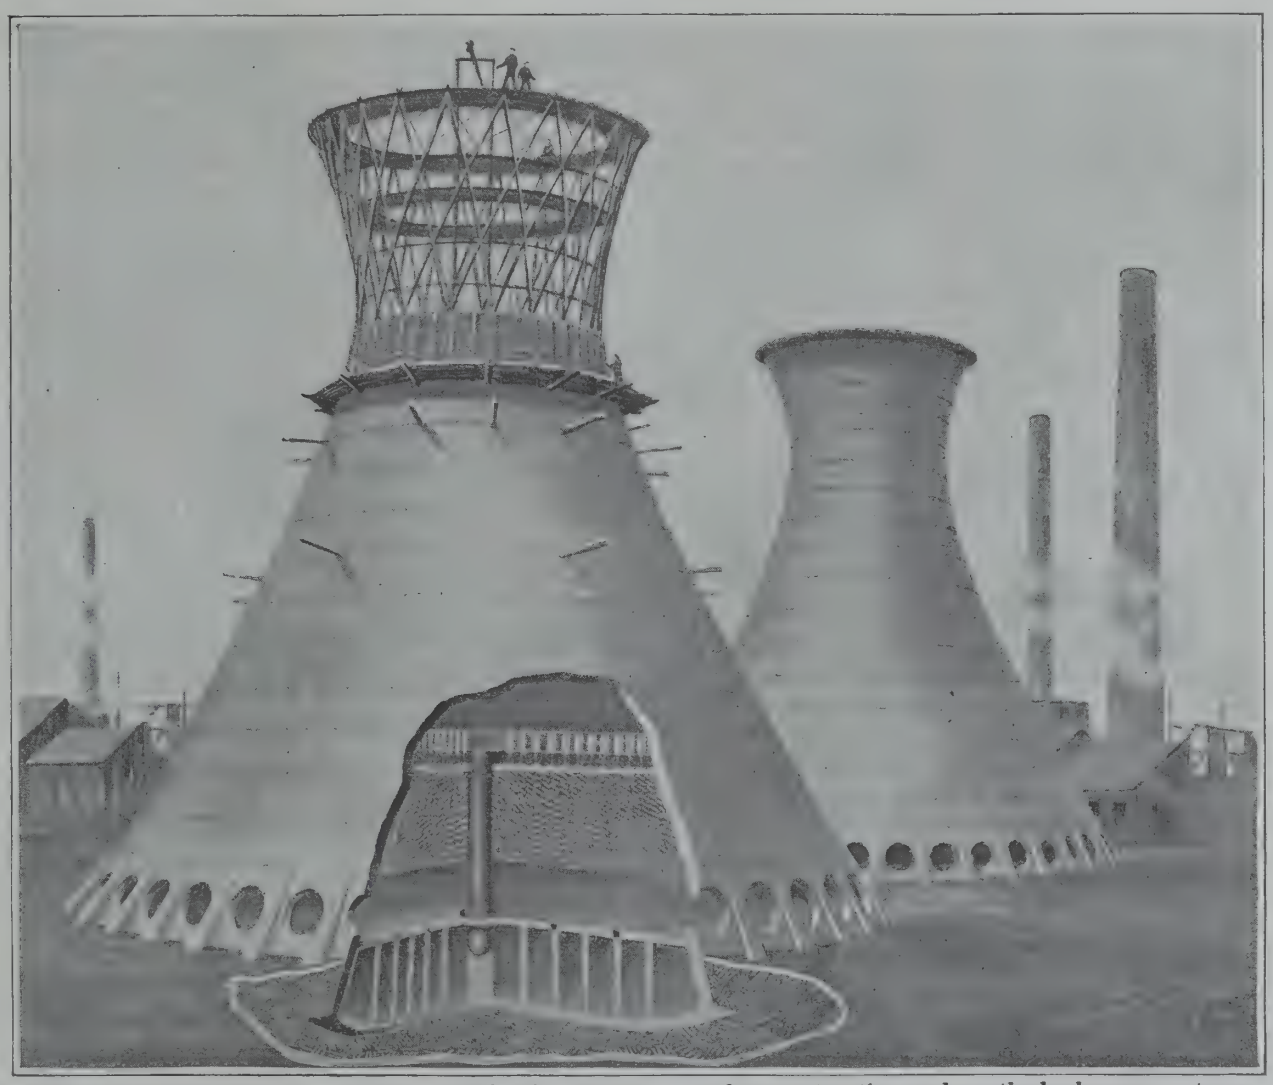
## Dutch Cooling Towers of Concrete

WHERE the electrical generating station is without an adequate supply of natural fresh cooling water, cooling towers, playing the same part in the station economy that the radiator plays in the operation of the automobile, are an essential. So vital to economical operation is successful cooling that a Dutch authority, writing in *The Electrician* (London) estimates that for every degree Fahrenheit drop in the temperature of the water ejected from the towers into the cooling system of the plant, steam consumption is reduced by one-third of one per cent. This makes it clear that the initial cost of cooling towers is a matter of small moment, since the attainment of high efficiency means that any cost likely to be incurred in construction will be regained through operating economies well within the life of the towers.

But notwithstanding long experience there is still a great difference in the efficiency of existing cooling towers, and the guarantees given by the builders are often not attained and are sometimes unattainable for physical reasons. A thorough investigation into the performance of a cooling tower is instructive, for faults are often detected, and in many cases improvements can be suggested. As the conservation of coal is of the utmost importance, in these days attention may well be given to this subject.

Our drawing shows the cooling towers at the central station of the Dutch State Collieries at Heerlen. Their construction and internal arrangement were the result of investigations made with several cooling towers of first class firms. The wooden laths are not drawn to scale, because their smallness would make them difficult to discern. This design of tower is an attempt to balance resistance to air flow and maximum cooling surface. The sketch shows how by a suitable arrangement of the lath the air passages were made as free as possible. The dry and wet bulb thermometers show that the air emerges almost saturated and sufficiently heated to cause a good draught. Many other cooling towers give too much resistance. The saturation with water-vapor and the heating of the air not immediately in touch with the falling water, are caused by diffusion and by the whirling of the air. The splashing water and the passages through the laths make it an easy matter to moisten and heat the air throughout. But it is very difficult to get an almost even temperature of the air on any spot above the timber hurdles.



**The latest cooling towers of concrete, showing one tower under construction and partly broken away to reveal the interior structure, and another completed**

As it was not possible to make the stream lines of air equal in length, uniformity in the conditions of the heated moist air over the whole surface of the cooling-stack was obtained by increasing the density of the spray from the center to the periphery. The radially placed gutters are slightly inclined, and the pitch of the spray nozzles is made smaller at the outer rings than at the middle rings.

The maximum cooling capacity is acquired only by adjusting carefully the dispersion of the sprinklers. Some inequality is unavoidable in heavy gales. But in this respect the cooling tower of circular section behaved well enough, and it was found that with large towers the best results were obtained when the radial screens, which as first designed divided the tower into sections, were removed. A cooling tower requires frequent and regular supervision. This must be effected by means of the dry and wet bulb thermometer. A water softener of ample dimensions must be installed when only hard water is available, and the collecting tank must be emptied and the water renewed at least once a year. The lath work of many cooling towers has collapsed through becoming covered with deposit.

A cooling tower is an hydraulic apparatus, and therefore it cannot be much overloaded. The cooling towers described in this article are each rated 6,000 kw., or 550,000 gallons per hour. The gutters are normally filled to about two-thirds of their depth, and as the water level rises with the square of the discharge through the nozzles the cooling tower can only be overloaded 25 per cent before the gutters overflow. The maximum capacity of the tower represented is about 700,000 gallons per hour. It is quite possible to overcharge a cooling tower much more than this, but the overflowing of the gutters is very bad for the efficiency.

As wooden cooling towers have a lifetime of only 15 years, and even in this space of time require many repairs, and as the initial costs and the expenditure on the upkeep of steel towers are prohibitive, the only material appropriate for cooling towers is reinforced concrete. The cooling towers represented in the illustration are constructed on the principle of an eggshell. Instead of supporting the dead weight and providing for resistance against the pressure of the wind by means of separate supports on the outside or the inside of the walls, or by beams, buttresses or other reinforcements, the wall is of double curvature, which withstands the pressure of the wind and supports the dead-weight by itself. The reinforcing rods are placed according to the straight describing lines of the hyperboloid and therefore require no bending. The construction although built with a minimum of material is of unexpected rigidity and strength, and therefore hardly more expensive than a wooden tower of about the same principal dimensions.

## New Plant Foods

DURING a recent meeting of editors of agricultural journals, held in Washington, the Department of Agriculture placed on exhibition specimens of edible plants which the department has introduced into this country and which have now passed from the experimental stage of culture to a permanent position among American crops. The fruits and vegetables exhibited, all of them grown in the United States at Government stations, included cassava root, dasheen tubers, udo shoots, passion fruit, white sapote fruit, chayotes, and a number of highly colored and extremely fragrant varieties of mango. A majority of these plants can be grown only in the South, but should make their way into northern and western markets. The department states that the udo, a celery-like shoot from Japan, is now grown successfully as far north as Nova Scotia. It is a salad vegetable, quite novel in taste and texture to Americans. The Department's activities in extending the range of crops must in the long run be of extreme value.

## How Many Miles to the Gallon?

WITH the gasoline situation that exists today, it is surely not too much to ask that every driver, if not for his own sake then for that of others, take all reasonable precautions to bring his gasoline mileage up to par, or even a little above par. The question of the operating economy as it affects the pocket-book of the individual owner in many cases seems an object hardly worth striving for. But quite aside from this is the effect on the general situation. It seems no remote cry to the day of gasoline rationing, when each car-owner may be told that he can have just so much gas and no more—that day has already found temporary place in the California calendar. Alike as a matter of valuable practice against the possible day of rationing, and as a means of postponing that day, everybody ought to seek the summit of gasoline mileage for his car.

Without disfiguring this page with unprovable assumptions and dry arithmetic, it can be calculated on an eminently reasonable basis that if every driver increased his mileage by a mere ten per cent, there would be enough gasoline saved to run about two-thirds of a million cars throughout the year. Twenty-five or fifty or even a hundred gallons unnecessarily burned in the course of a year by the individual driver is not going to make or break anybody, even at forty or fifty cents a gallon; but gas enough for two-thirds of a million cars might well make or break the automobiling community. That the good performance cuts the gasoline bill is immaterial—what we are driving at is to cut the demand for gasoline. There are many ways in which intelligent operation can do this. The thing is largely in the hands of the man who handles the throttle and the pedals. Most motors carry an unnecessary load somewhere. Brakes that drag, as shown by their being hot after the car is allowed to coast to a standstill; a motor so stiff that it will not rock freely when cranked by hand with a close throttle; undue friction in the running gear as shown by a car that is hard to push—all these things consume power, and have been known to raise gasoline consumption nearly one hundred per cent.

Then there is scope for much care in keeping the motor in good operating condition. Leaks past the piston or leaky valves allow a respectable fraction of the power to escape. A cylinder that does not fire wastes one-twelfth of the gas in a twelve; it wastes one-quarter of the gas in a four. Loose joints in the complicated series of connections that lead from the piston to the rear wheels do not waste power in such large blocks, but they waste it, be sure of that.

Carburetor adjustment is something of which many drivers know next to nothing. It is true that an over-rich mixture gives better acceleration, but at a ruinous price, not merely in the direct consumption of fuel but indirectly through the deteriorating effect on the engine. It is unfortunate that a rich mixture must be used for starting and until the motor warms up; but do not make the carburetor adjustment permanently rich to take care of this. You are given a carburetor dash control to cover this very ground; use it. Make an economical adjustment of the needle valve with the engine warm; get the temporary rich mixture with the dash control.

Do everything possible to keep the motor warm while in use. The gasoline of the day will not vaporize into an explosive mixture unless the intake manifold is hot, and everything that contributes to this condition will help fuel economy.

A final point that escapes many drivers is the effect of unnecessary speed variation. We would not be interpreted as advocating reckless driving, but the fact is that every time you slow down with the expectation of speeding up again you are laying up a debt to the laws of motion which you must pay by burning gas. Acceleration burns up gas, deceleration means failure to get the most out of the gas you are burning during the period for which it lasts. So drive at a uniform speed, so far as feasible.

## Wanted—A Proverb

SINCE our publication of the details of the Michelson-Morley experiment, we have had a number of communications from our readers, asserting in more or less positive terms that this experiment proves nothing. The argument runs about like this:

Suppose a swimmer or a rower make a return trip upstream and down, contending with the current as he goes up and getting its benefit when he comes down. Obviously, says the self-appointed critic, since the two legs of the journey are equal, he derives exactly as much benefit from the current when he goes with it as he suffers handicap from it when he goes against it. So the round trip must take exactly the same time as a journey of the same length in still water, the argument applying equally in the case where the "swimmer" is a wave of light in the ether stream.

It seems extraordinary that so many people able to take an interest in the Michelson-Morley experiment and the Einstein theories should be ignorant of the fundamental principle here involved. We had at first doubted that this was a subject worthy of discussion on this page, but the extent of the misapprehension has resolved this doubt. So let us look at a numerical example.

A man can row in still water at four miles per hour. He rows twelve miles upstream and back, in a current of two miles per hour. At a net speed of two miles per hour he arrives at his turning point in six hours. At a net speed of six miles per hour he makes the downstream leg in two hours. The elapsed time for the journey is eight hours; in still water he would row the twenty-four miles in six hours.

If we were to attempt an explanation of this result in words we should say that by virtue of the very fact that it does delay him, the adverse current prolongs the time during which it operates; while by virtue of the very fact that it accelerates his progress, the favoring current shortens its venue. The careless observer realizes that distances are equal between the two legs of the journey, and assumes that times are equal.

If the journey be made directly with and directly against the stream of water or ether or what not, retardation is effected to its fullest extent. If the course be a diagonal one, retardation is felt to an extent measurable as a component, and depending for its exact value upon the exact angle of the path. Felt, however, it must always be.

The primary purpose of this editorial, of course, is not to correct this misunderstanding—greatly as it may call for correction. Those who have been in ignorance of the phenomenon just demonstrated necessarily lack any knowledge of algebra, since we are acquainted with no text in the elements of that subject which does not contain problems revolving about swimmers and rowers, or in late years aviators flying with and against the wind—problems which involve this principle and which cannot be solved without its application.

With the man who asks us to explain the Michelson-Morley experiment to him, because so far as he can see it is incapable of giving a positive result under any conditions, we have all the patience which his desire for enlightenment demands. We should think he might improvise a numerical case that would enlighten him, but if he can't or won't we are quite ready to do it for him. But with the man who from the depths of his ignorance calmly informs us that the Michelson-Morley experiment is foolish, that the eminent scientists who originated it and those who have repeated it after them and those who have used it as the basis of their theories and their teachings are simple-minded—that the whole world of science is chasing a shadow—well, when this happens we feel the inadequacy of the proverb about fools and angels.

Will not someone present us with a brand new pearl of wisdom to cover this ground?

## The Psychology of the "Rider"

AT a point which we shall not try to localize in the development of our governmental procedure, the astute gentlemen whom we are in the habit of sending to represent us in the legislative halls made a scientific discovery of great importance—to them. Reduced to its simplest terms, this is it: If you have a piece of legislation which you know is vicious or predatory or in any way questionable to the extent that its passage on its merits seems difficult, hook it on to some general bill of importance in the form of a "rider." It will then in all probability come through with flying colors.

That the general bill thus utilized has nothing to do with the subject of the rider is understood. That the practice of thus jamming through legislation which shrinks from scrutiny is reprehensible will not be questioned. That this practice is on the wane we think will be admitted, in spite of recent riders which have attracted wide attention. But in any event, our interest here is with another point.

It would seem a reflection upon legislative intelligence to assert baldly that a measure which could not pass on its merits could be passed if tucked away in the bowels of the general appropriation bill. Yet experience has shown this to be a fact. Why?

Doubtless the reason is a complex of numerous legislative emotions and desires. In the first place, there will be members who want to vote for the measure which is thus disguised, but who are not sure that their constituents will stand for it. These men feel, and experience justifies them in this, that their vote on the general bill will not stand as a specific record of their attitude on the question of the rider, a record which may rise to harass them during the period immediately preceding the first Tuesday after the first Monday in November. To an extent this is a reflection upon their constituents; to this extent their constituents have earned such a reflection. But the constituent may be excused if he takes the attitude which probably accounts for the greatest number of votes in the legislative body itself.

There is always a good number of members who have steered a general bill through the perils of committee and floor. Their efforts are not centered during this struggle in keeping the bill intact or free of extraneous matter—they are well pleased if they can preserve enough of its original form to be recognizable. And when it finally sees the light of the open house and comes to vote, they and many others swallow the rider, fearing that if they did not do this the main bill might not fare so well in its essential features on going through the mill a second time. Few legislators indeed will sacrifice what they want for something that they don't want; and on the whole the constituency is of the same mind.

We must not forget, either, that the support of a rider comes always from those who are actively and materially interested in its passage; while the opposition usually is a matter of principle, and far less vigorously prosecuted. Then on a close line-up over the big bill, the votes of the supporters of two or three riders might make all the difference between passage and rejection.

The committee system affords another reason for introducing legislation in the form of a rider. The committee to which a general bill goes may have the necessary majority to report the rider, where the committee to which the minor measure would go if introduced as a separate bill lacks that majority. And if the rider is really vicious but looks innocent on the surface, it is less likely at the hands of the busy general committee to get a thorough discussion that will expose it. So when we have considered all the possibilities, it turns out not to be at all surprising that riders succeed where special bills fail; and the fact that today riders get more and more pitiless publicity, that more and more often they fail, is really an indication of considerable advance.

## Electricity

**Our Radio Stations** are steadily growing in number. According to *The Wireless Age*, the Government shore radio stations number 135 of which 88 are in continental United States, 20 in Alaska, 19 in the Philippines, 3 in the Canal Zone, 2 in Hawaii, and one each in Porto Rico, Guam and Samoa. The Government ship stations total 470.

**Wireless Research in India.**—Upon completion of the research work, which is being done in India by a staff of scientists in order to find means of overcoming the meteorological obstacles which interfere with the proper working of wireless telegraphy in India during certain seasons of the year, there will be a great extension of the wireless system in that country.

**Combined Ceiling and Reading Light.**—An ornamental lighting fixture with a center light that may be pulled down close to a table for use as a reading lamp has been developed by a Western concern. Ordinarily the fixture has the appearance of the common four-light fixture, but the center lamp has a flexible cord wound on a reel in the fixture which unwinds when the lamp is pulled down.

**The Use of Induction Motors.**—The fusing of an alternating current motor should be determined by the normal running current, and should be regulated by the starting fuse, if such fuse does not exceed the normal running current by a certain specified amount, this value to be somewhat below the maximum current at which such motor may operate for an indefinite time; and it is also regulated by overload releases, and by time-limit circuit-breakers. The wiring and the fusing are separate problems.

**Night Landing by Means of Radio.**—Wireless calls for aid sent out by a Government mail plane which faced a descent in the dark, enabled the plane to make a safe landing, according to *Wireless Age*. Delayed an hour by a wind storm on the last lap of a journey from New York to Chicago, the radio operator on the plane sent out calls while approaching Chicago to light the landing field and prepare for the machine's descent. The message was picked up by the wireless operator at Great Lakes Naval Training Station and on several amateur wireless outfits and relayed to the landing field by telephone. The plane, which carried three passengers and 1,200 pounds of mail, landed at eight o'clock.

**High Speed Wireless.**—Manual operation is doomed as far as long-distance radio traffic is concerned. The ever-increasing cost of high-powered stations makes it necessary to handle a far greater volume of traffic than can be handled by the usual method. Thus some of the present transatlantic stations are operating at 50 words to 100 words per minute by means of automatic transmitters and receivers. In England experiments have been going on for some time with automatic transmitters capable of a normal speed of 450 words per minute, and even 1,000 words per minute during demonstrations. The recording is effected by means of a special electro-chemical apparatus. This apparatus consists of a specially prepared paper drawn between a roller and a marking pointer. The arrival of a signal causes a current to pass through the paper, producing discoloration.

**Elimination of Insulator Failures.**—In a recent issue of *Electrical World*, Mr. E. J. Kallevang describes methods of detecting faulty insulators, and notes the fact that insulators that have been stored several years are found to have deteriorated. This deterioration may be due to mechanical stresses or to the electrical test that has been applied at the works. It is observed that insulators near railway tracks break down readily. This is supposed to be due to sulfur fumes, which may attack the cement and promote crystallization. It is also suggested that in such cases the insulators may reach higher temperatures due to their blackened surfaces. Methods of testing by the oscillator or by the megger are described. It is believed that the higher percentage of failures in the top unit in suspension strings is due to the fact that it is subject to more abrupt changes in temperature. Trees which are near the line, or overhang it, are a frequent source of damage.

## Science

**The International Research Council.**—A report of the proceedings of the first meeting of the International Research Council, held in Brussels in July, 1919, has been edited by the secretary, Sir Arthur Schuster, and published in London by Messrs. Harrison & Sons.

**Thefts of Platinum.**—It is said that organized thefts of platinum are taking place throughout the United States. The matter has become so serious that, at the suggestion of Dr. W. F. Hillebrand, the American Chemical Society has appointed a committee to consider whether legislation may not be recommended to Congress with a view to dealing with the situation.

**The Norwegian Geophysical Commission.**—A new body known as the Geofysiske Kommission represents a union of Norwegian institutions and explorers in the domain of hydrography, terrestrial magnetism and the study of the aurora borealis. With the aid of funds granted by the Norwegian Government the commission has begun publishing a series of memoirs, *Geofysiske Publikationer*, in English, French and German.

**Recent Surveys in Spitsbergen.**—A systematic survey of Spitsbergen has been carried out annually by the Norwegians since 1906. During the year 1919 a party of surveyors, hydrographers and geologists, headed by Adolf Hoel, mapped a total area of about 520 square miles, and made hydrographic surveys over an area of about 1,620 square miles. A chart recently published by the Norwegian Hydrographic Office, of the Arctic Ocean from Norway to Spitsbergen, embodies the results of the hydrographic surveys of the Spitsbergen coasts down to 1918.

**Weather Forecasts by Wireless Telephone.**—The distribution of weather reports and forecasts by radiotelegraphy has made great progress since the war, and is no longer intended primarily for the benefit of mariners. The wireless telephone also has recently been pressed into the service of meteorologists. Arrangements have now been made so that the weather forecast sent out by this method every day at 10 A. M. from the Physics Department of the University of Wisconsin can be received, with suitable apparatus, anywhere in southern Wisconsin. A U. S. Weather Bureau station is located at the university.

**Anthropology of Polynesia.**—Dr. Henry Fairfield Osborn has recently called attention to the urgent scientific reasons that exist for immediately taking up an energetic and systematic study of the anthropology of Polynesia; one of the undertakings that will, it is hoped, be set on foot by the forthcoming conference in Honolulu on the problems of the Pacific. Dr. Osborn states that the material for such an investigation is disappearing with almost incredible rapidity. The ravages of influenza during the past two years have swept away a large part of the members of the Polynesian race. The survivors on certain islands constitute a very small percentage of the original population. Researches on the physical anthropology of the Hawaiian group have recently been begun as a cooperative enterprise of the Bishop Museum of Honolulu and the American Museum of Natural History of New York.

**Fungi That Damage Canvas.**—Major W. Broughton-Alcock of the British Army has made some studies on the fungi that cause black and brown spots on canvas tents, awnings, etc., and that bring about a more or less rapid destruction of such articles. A note on the subject by J. Ramsbottom appears in *Nature*. The investigations were carried out partly in Malta, where, it is said, awnings last only about a year. The principal destructive agents in the case of cotton- and flax-made canvas were found to be *Macrosporium* and *Stemphylium*. The variation in the color of the spots is found to be due to the presence of various other fungi in association with the genera above mentioned. The first signs of fungoid growth appear on the inner side of the roof portions of tents and marquees. Often within three months pressure on the spots made by the fungi leads to perforation, or a strong wind causes tearing. Experiments showed that the Willesden (cuprammonium) method and cutch treatment prevented the growth of the fungi.

## Automobile

**Motor Farming Suits Italy.**—Italy has disposed of about all of the 6,500 farm tractors bought from the United States in 1917 and of a number purchased locally. In the meanwhile Italian farmers have learned the benefit of motor cultivation and will naturally continue to use these implements in large quantities. In 11 months of 1919 that country imported 8,114 metric tons of reapers, mowers, tractors and other farm machinery.

**British Motor Tax Based on Road Wear.**—The new taxes which it is contemplated, will be levied on motor vehicles in the United Kingdom, will be based on the amount of road wear, according to a statement of the Ministry of Transport. The horse-power will be the unit for the calculation of the tax on private motor vehicles, their weight the unit for commercial vehicles, and the seating capacity for hackney carriages and omnibuses. Motorcycles will be taxed on their weight with an added amount for sidecar or trailer.

**A Windshield Compound.**—Among recent automobile novelties is a liquid which is easily applied to a wet or dry windshield with cloth, sponge or tissue paper. The manufacturers claim that one application will keep the glass clear for 12 to 24 hours, through the most severe storm of rain or snow—no matter how hard the rain, hail or snow beats, it will not stick. The advantage of this over the more usual methods of keeping the shield clear is that one does not have to remove one hand from the wheel while driving. The makers emphasize that the substance is not a grease or a soap, but a chemical compound quite different from either of these classes.

**New German Self-Starter.**—A description of a German self-starter which is in reality a device for filling the firing cylinder with a strong mixture so as to permit of a starting on the switch—for use with the Bosch self-starting coil—has appeared in a recent issue of a German automobile paper. A supplementary jet is attached to the carburetor, and gas is drawn by means of a hand-pump and forced through a small chain-driven distributor to the required cylinder. The fixture for the cylinders consists of a Y adapter, one arm containing a non-return valve through which the gas is forced, and the other arm containing the sparking plug. The advantage claimed by this device is that it can be fitted to almost any existing motor at very little expense.

**Easily Located Carburetor Troubles.**—When an automobile engine, after starting, runs for a minute or two and stops, the first place to look for the trouble is the gasoline feed line. A partial stoppage in the fuel supply pipe will lessen the flow of fuel so that the float chamber fills slowly. On being started, the engine will quickly consume the gasoline in the chamber and stop. Another possible cause for the fault is the float sticking, and if the float sticks in the high position the flow of fuel will be greatly lessened or may be stopped entirely. Water in the gasoline is also troublesome as a drop may get into the feed pipe or the spray nozzle and interfere with prompt starting or reliable feed of fuel. Lint or other foreign matter around the filter screen in the feed line is also responsible for restricting the fuel flow, especially in cars using the gravity feed system.

**One Truck Hauls More Than Seven Teams in Road Contracting.**—An interesting comparison has been made in a recent number of the *Oklahoma Highway Bulletin* with regard to teams versus motor trucks in the hauling of road building materials. A road contractor while doing state aid road work of hauling crushed stone, employed seven teams, seven drivers and one 3½-ton motor truck. The seven teams had each hauled three loads of 1½ yards per day, a total of 4½ yards daily. By motor truck he hauled 33 yards each day. Figuring the cost of each team and driver at $7.25, the total amount was $50.75 per day for seven teams. The 3½-ton motor truck actually hauled more material each day than the seven teams. The operating expenses of the motor truck figured to $18.40 per day, thereby effecting a daily saving of $32.35. The distance of the haul was 4½ miles each way, or a total of 9 miles.

# Building in the Wilderness

## Where the Engineer Has to Lay Down a Railroad to Take Him to His Job

By A. R. Surface

THREE hundred thousand tons of construction material is the amount estimated as necessary for the Hetch Hetchy Dam and other work connected with the Hetch Hetchy water supply enterprise of San Francisco. A large part of this must be carried far into the foot hills east of the city—far enough in fact to attain an elevation of some 3,500 feet above the sea in a valley location. The great dam, the principal item of the whole work, is to be located there in the Sierra Nevada many miles from the nearest ordinary railroad. The intervening country is very difficult to traverse; so that one of the serious problems that had to be faced was how to get the enormous tonnage from an existing railway to the points of use notwithstanding the difficulty of the topography. Naturally, there were two alternatives—a road adapted to heavy motor trucks and tractors, or a railroad. The second was the one chosen. The location survey was completed just about five years ago.

It may surprise some that it was decided to build a railway rather than an ordinary road. It is a matter of calculation. The report of the chief engineer, Mr. M. M. O'Shaughnessy, five years ago was to the effect that 233,000 tons of equipment and material would call for transportation. It was estimated that the cost of hauling by motor truck would amount to $3,095,000 and that the expense by the railroad method would be only $2,010,000. From the point of view of the water-supply project alone, a saving of $1,085,000 would be effected by the railroad. Apparently, the amount of material estimated as necessary has considerably increased since that early date; so that the saving is to be set higher yet. In addition, the transportation is to be viewed as rather likely to be more rapid with the railroad. Further, such a road would earn something from outside freight and from passenger service, and would remain at the end a very considerable asset. However, there is a point which needs to be added. At the time of the estimate it was considered necessary to use double sacks with the cement when transported by motor wagons. As a very large percentage of the total freight would consist of cement, the extra expense of 11 cents per unit constituted a heavy debit against the motor truck. The estimated cost of the railroad seems to have been considerably in excess of the actual expense, as the contract was let for $1,543,080.74.

The Hetch Hetchy Railroad connects the site of the great dam with the immediate vicinity of Rosasco which is a station on the Sierra Railway of California. Between the two terminals, Hetch Hetchy Junction and Damsite, are 68 miles of standard-gage track. Here is a very considerable little railroad, built primarily as a means of constructing something else. Doubtless, the road will be maintained after all construction work on the great project is completely finished. This construction railway is a real railroad and not a pretense nor a freak. There is no grade amounting to more than 4 per cent but the curves are sharp.

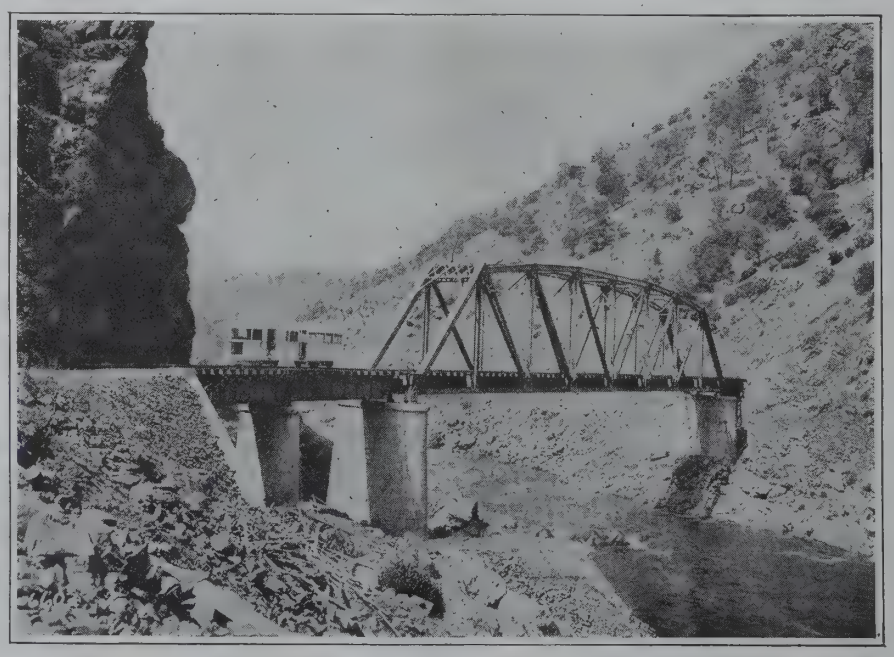
The general direction of the road is east and west, though naturally it winds about in order to take advantage of topographic features. At the Junction the elevation above the sea is 935 feet, but the line drops to 625 feet soon after leaving this terminus. This drop is made in the course of but 9 miles of track and has of course to be later on recovered. The object in view was to get across the Tuolumne River, the very stream which in fact forms the foundation of the water supply project. This river is subject to floods, but the bridge carries the track over at 12 feet above high water. Once on the other side of the stream, the railroad naturally stays in the valley; but it does not always cling to the river itself. In order to get uphill and downhill without excessively steep grades and without heavy expenditures on construction, it was found necessary to use sharp curves and plenty of them. The gentlest curvature round bends is 30 degrees while there are numerous curves in the range 18-26 degrees. The curves if put together and arranged in one circular direction would yield nearly 100 complete circles. The most considerable elevation attained is 5,064 feet at Poopenaut Pass. This is a good deal higher than any regular railroad attains in passing over the Appalachians in the eastern United States. The road is 50 miles long from where it crosses the Tuolumne until it reaches this highest point, so that the 4,439 feet of difference in level is attained at the average rate of about 88¾ feet per mile. On the western side of the pass the descent is pretty steady on heavy grades until Damsite is reached, where the elevation is 3,869 feet above the sea. The drop of nearly 1,500 feet is accomplished in 9 miles, or at the average rate of about 166 feet to the mile.

This road in the mountains had to cut its way largely through real rock. Of the 1,000,000 cubic yards of excavation more than half was in rock. Naturally, there are many ravines, little valleys and little canyons that are crossed. In general, timber trestles and the like were employed. Some 500,000 board-feet or more were consumed in this work.

The subgrade of the roadbed is, for the 59 miles from the Junction to the summit of the Pass, 16 feet in width. For the remaining 9 miles from Hog Ranch down to Damsite in Hetch Hetchy Valley, the width is 6 feet greater. When the railroad is no longer needed for the work at the eastern end, the track will be taken up and the roadbed resurfaced. There will be then left a fine road for automobiles.

Many of my readers will ride over this nine-mile stretch despite the fact that it is now occupied by railroad rails, cross-ties and ballast, for already the Yosemite Park Company is operating tours from Yosemite to Damsite. An ordinary motor bus brings the tourists to Hog Ranch—or, Mather as it is now more aesthetically termed—by travel over a route 35 miles long. From Mather down to Damsite, the conveyance is a special motor bus which runs on the railway track.

With a view to facilitating the work at the Hetch Hetchy Dam and of providing a means of turning trains, a loop has been added to the railroad at the eastern terminus.



A typical bridge along the line of the Hetch Hetchy road

## Use of Rare Sugars as Medicine

THE so-called rare sugars are used to a considerable extent by the Medical Corps of the Army, and by the profession in general. One of the principal uses to which they are put is the differentiation of bacteria, for which purpose they are invaluable. For some time the Bureau of Standards has had presented to it for test a number of these rare sugars. Owing to the large demand for one of these sugars, known as d-Mannite, the Bureau has undertaken, at the request of the War Department, the production of a considerable quantity of this substance. The Bureau's investigation has finally developed a method whereby pure white crystals of d-Mannite can be produced by two crystallizations from the crude manna.

## The Third Degree for the Baseball

**By Edgar Lockhart**

WITHOUT baseball lots of Jacks in America would be mighty dull lads. Without the National pastime, countless thousands of fans who now gain recreation and pleasure in watching "Babe" Ruth, "Ty" Cobb and other veterans of the diamond in their base-stealing or fence-busting specialties would be glum and disconsolate. Without this typically American sport our athletic initiative would be jeopardized. Baseball is our invention, our possession and one of our most fruitful resources for demonstrating to the world our athletic supremacy. And every American youth at one time or another does his best to sustain the prestige in which the great game is generally held.

A baseball for service and maximum utility must be adapted to withstand the shock of batting and at the same time must possess sufficient resiliency and buoyancy for flight and catching in the hands of the different players. The American baseball preëminently is a development from the English cricket ball. The English originally used a rubber composition ball and later a ball having a central core with a resilient layer or cover on the exterior. Finally a solid cored ball surrounded by filamentous windings was devised.

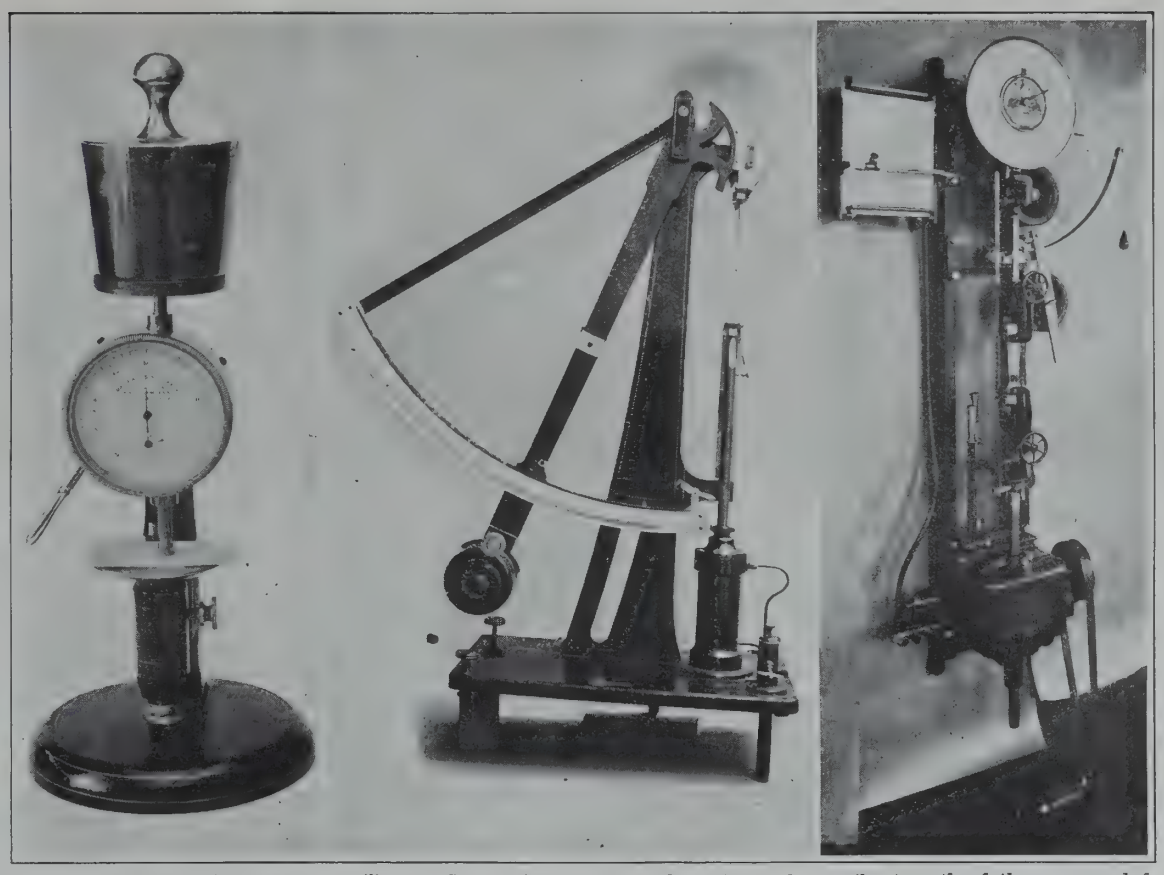
The next step in the ball line developed by ambitious inventors was the initial baseball which consisted of yarn wound on a resilient core and encased in a leather cover. H. A. Alden, Mattewan, N. Y., on December 17, 1867, was granted the first patent rights on a baseball which consisted of a composite of rubber, lead and cork with sulfur used to vulcanize the compound. Under practical service, this type of ball proved unsatisfactory with the consequence that its originator the following year turned out another model ball made of ground cork encased with cord windings and surrounded with a rubber compound cover. Later this ball—which proved fairly serviceable—was improved by the substitution of a leather for a rubber cover.

In the early history of the game freak balls were numerous, the prize innovation of this description being a ball with a bell as a core which rang when the ball was batted. This ball was invented about 45 years ago. Otherwise than as an asset to keep the players from going to sleep, this comedy baseball possessed no merit. However about the same period, patents which subsequently proved valuable were taken out featuring the use of a square reefing knot and the herring-bone stitch.

In 1883 B. F. Shibe devised the use of a plastic cement and an india rubber solution for holding together the core of the ball and the yarn wound upon it. This arrangement permitted the cover to slip on the ball when batted without in any respect damaging the interior. One of the latest inventions of Mr. Shibe—perfected during the last decade—gives to the best baseballs increased uniformity and rigidity of structure. He uses a central cork core and winds around it a layer of yarn and rubber, vulcanizing this to the desired degree of hardness and resiliency. Such a core permits of winding the yarn very tight and hence results in a better and more durable ball.

Horsehides imported largely from England and Russia—although during the war domestic baseball manufacturers had to depend largely on native supplies of skins—are used for baseball covers as well as for patent leather, uppers for shoes, thongs for whips and for sewing harness. Horsehides are tough, durable, wear well under rough usage and are capable of with-

(Continued on page 233)



*Left:* The instrument that measures resiliency. *Center:* Apparatus for determining the tensile strength of the yarn used for stitching or winding. *Right:* Machine that tests the force necessary to rip the stitches out of the ball—something quite different from straight tensile strength

**How the Bureau of Standards separates the sheep from the goats of baseball manufacture**

## Handling High Voltage with Bare Hands

**By George Gaulois**

FOR many years there has been no startling improvement in the method of working high voltage lines. Year by year there has been a constant tendency toward increased voltages. The quality of line materials has kept pace with the requirements of up-to-date line construction, but little thought has been given by the electrical fraternity to the urgent need of better and safer equipment for maintaining the line in a high state of efficiency.

It has remained for an American engineer to introduce a new method of working on high voltage circuits, which makes it unnecessary to shut off the power for protracted periods with the resultant inconvenience to electric power users. This method consists of putting the protecting insulation not between the man and the line, as has been done in previous efforts to attain the desired result, but between the man and the ground, thus eliminating the cumbersome, long-handled insulated tools which have heretofore been used on live wire work. The problem has been one of securing the proper insulation, and this problem has been solved in the safety staging which is shown in the accompanying illustration, and which forms the cover subject of this issue.

The safety staging, made of carefully selected hard wood submitted to a special drying and impregnating process, has been on the market for some time. It is only recently, however, that this treatment has been perfected to a point where the designer has felt justified in eliminating all insulated tools and allowing the men to work direct on the live line with bare hands. With this staging properly placed, which is but the matter of a few minutes, the man enters it and by so doing interposes between himself and the pole (or steel tower) an insulating medium capable of withstanding over one hundred thousand volts. Guards are so placed as to prevent any possibility of accidental contact with a grounded arm, guy wire or another phase of the circuit.

The man working on the safety staging is free to touch the live wire at any time. In grasping the line there is no discomfort whatever to the man, although there is a slight "pip" similar to a static discharge.

(Continued on page 234)

# Muggy Days and Thirsty Air

## The Mechanism That Keeps Us Cool, and Why It Fails to Work in Damp Weather

By Professor Alexander McAdie

IN the SCIENTIFIC AMERICAN for May 29, 1920, a leading editorial of rare literary charm describes the paramount importance of water. We are shown how all modern engineering depends in the last analysis upon the successful handling of some water problem; and that "by far the greater portion of the human struggle for collective existence hinges on the control of water, keeping it out of the places where it is not wanted and insuring its presence in those locations where it is desired." It is free to flow, it freezes, it melts, it fetches and carries; it is at times the most docile of servants and again it breaks all bounds and spreads destruction far and wide.

There is just one other substance that is as important to man's welfare, and that is *air*. Man quite early in his career attempted with success the mastery of water; but not until our own day have engineers been called upon to master air. They now put it to work, and in the pages of the SCIENTIFIC AMERICAN one can read of many practical applications: carrying heavy bricks, as well as light cotton; sucking coal from the bunkers on the destroyers; cooling the wireless spark; revitalizing the air in engine rooms; ventilating the kitchen; operating the laundry; under pressure digging a way beneath river or through rock bed.

Geologists tell us that in arid regions the erosive power of the wind, that is, the unharnessed sand laden air, changes the face of nature more than the washing rains; and that the action of air is more extensive and persistent than the action of water. What then of the combined effects of water and air upon those who walk the earth and breathe the air? Here is a problem in human engineering; and a problem that concerns us all as no other ever can.

### The Water in the Air

Air carries water in the form of vapor, as well as in the liquid or solid form. And so while it has been customary to speak of the *capacity* of air for vapor, and in a way we might describe this condition as air *thirst*, we of course realize that the air itself has no real capacity for vapor, and that the quantity of vapor present is not a measure of any physical property of air any more than a quantity of air in water would be an essential part of the water. Like man and wife, air and water vapor pass as one, and in many problems we deal with the combination or mixture; nevertheless each is an entirety, each has its own characteristics. But it makes a vast difference in our feeling of comfort whether the load of vapor which the air carries be light or heavy and whether the temperature at the time be high or low.

There are days, muggy days we call them, when no one is comfortable. Even the best natured of our friends are uneasy; if not indeed fretful. We are all irritable and we know not why. On another day, things are different and we regret and wonder at our crossness. Oh, for the engineer that will regulate, not indeed the weather, but the essence of all weather, the load of water vapor which the air carries. Then all of our days will be days of maximum comfort and minimum irritability. John Hay wrote of such days, calling them Castilian days, days of quiet charm and perfect rest; and probably he was entirely unaware of the fact that with a heavier load of water vapor and higher temperature those same days would have been transformed into the trying, muggy hours of our mid-summer climate.

One Castilian type of day occurred on Easter, April 8, 1917. The relative humidity at Blue Hill Observatory went down to 2 per cent. In the records for 35 years we have not found so dry a day. Possibly it was the driest day in a century. Some rather precise measurements showed that in every five cubic meters of space there was only one gram of water vapor, when ordinarily there would be one hundred grams. The weight of water vapor present is not the relative but the *absolute* humidity; on this date both were extremely low. It was a pleasant day—although there was a state of air thirst that a full-fledged simoon might equal but could hardly surpass.

It was not a chinook wind or foehn effect, however, where dryness is due to a previous robbery of the moisture from the air. We cannot clearly identify the robbers; we are unable to say where the air was originally lifted and, following expansion, cooled; and a certain amount of water vapor abstracted. Somewhere, far to the west, probably beyond the Mississippi, the moisture was stolen; and the dry air moving slowly to the southeast, was dynamically heated, chiefly by horizontal compression. Air rising loses its load of vapor because the cooling brings about condensation and the water drops out. Air falling generally becomes warmer and drier because its thirst is greater. And for reasons which are given later we can stand warm dry air much better than warm wet air. Indeed there is a direct relation between health and humidity when the temperature is high; and we may even go further and connect happiness and certainly personal comfort with humidity and heat; or in more exact terms comfort is a function of evaporative cooling which in turn depends largely on humidity.

An interesting example of the above relationship can be found in the studies of relative humidity made during the early months of this year by Ellsworth Huntington at Boston hospitals. It seems that in surgical cases the recoveries were more pronounced when moderate humidity and temperature followed high humidity than under other conditions. And what is true for the sick and suffering may hold also for the well and strong in that the sum total of health and happiness may be increased if we can only control the moisture and heat environment. In this control there are three prime factors, ventilation, transpiration and stimulation.

Of these ventilation is perhaps most clearly recognizable in its results, and it is also within our power directly to control it. Let us take so simple a problem as the ventilation of a school room or assembly hall and follow the reactions on poor mortals, as the air thirst varies.

*THE good old bromide, "It isn't the heat as much as it is the humidity," is familiar to all of us. No argument is needed to convince us that a damp hot day is more disagreeable than a dry hot day. Yet to many of us this must have been a good deal of a puzzle. Water, especially cool water, is a universal cooling agent. The moisture present in the atmosphere on a thoroughly uncomfortable muggy day often is distinctly cold and clammy, so that in the moments when we cease steaming we feel the premonitory symptoms of a checked perspiration and an oncoming cold. Yet this moisture doesn't cool us. Why? Dr. McAdie answers this question, pointing out that when the air is saturated it cannot take up our perspiration, and that when we have perspiration without evaporation, nature's process that is designed to make us cool acts only to make us more uncomfortable than ever.*—THE EDITOR.

### The True Rôle of Ventilation

Ten years ago Dr. Gulick, for the Russell Sage Foundation, raised the question whether the air in school rooms directly or indirectly caused the fatigue and lowered vitality so frequently noticed. Was there a subtle poison, such as carbon dioxide or carbon monoxide, or was it lack of oxygen, or was it too much humidity? As finally phrased by the physician, the problem read: "Does anyone know in what respect our present schemes of ventilation are wrong? Why do delicate children and tuberculous persons get well out-of-doors, and fail to do so indoors, and what do we need to do *to make indoor living as healthy as outdoor living?*" (The italics are ours.)

This is a challenge to engineers, especially ventilation experts, also to chemists, physicists and physicians. All are directly concerned. The mental attitude of the various professions to the problem is most interesting. The engineers, for instance, hold that while the problem has a dual nature, being partly engineering and partly hygienic, the engineering part has all been attended to; but the hygienic part, if we may use the words of a very distinguished engineer, "is in very poor shape. It is up to the doctors and not for the engineers to settle." Meanwhile the physicians think it is essentially a question of sufficient supply of fresh air, and therefore an engineering problem. The chemist holds that there are no poison gases in the air, or not enough to produce the results described. The physicist harbors the suspicion that the ventilation experts are not up on the physics of saturated and unsaturated space; that while blowers and fans may furnish enough air, the effect of air thirst has not been sufficiently studied.

The older notions about poisoned air due to exhalations from the body, have been given up. Carbon dioxide was the particular gas which was held responsible and while there is no doubt as to its toxic character there is too little of the gas present, to prove injurious. Under usual conditions, outdoor air contains only three parts in ten thousand of this gas. The specifications for nearly all modern school buildings call for air renewal at the rate of a cubic meter per hour per pupil, and under such conditions the carbon dioxide limit will never be reached. So we may dismiss the poisoned air explanation. But even the best specifications are silent regarding the *thirst trait* of the incoming air, that is, its evaporative and cooling capacity and presumably its vitalizing- or comfort-bringing power.

Let us at this point, correct the story, as it is commonly told, of the Black Hole of Calcutta, and show that it was not poisoned air which caused the death of 123 of the 146 prisoners; but high temperature and a minimum air thirst or saturation. The night was hot, damp and still. There could be no cooling of the skin by evaporation, and profuse perspiration without evaporative cooling meant only extreme discomfort. Fatigue and exhaustion of the sweat glands caused death.

How different was the experience of the soldiers in Mesopotamia during the recent campaign. The heat was intense but the thirst of space for water was very great. Perspiration quickly evaporated and the skin temperature, or *sensible* temperature, was lowered. All that was necessary was to drink enough water. In cases of heat stroke (for these did occur) wet sheets and spraying were resorted to, as substitute sweat layers; and in nearly every case, a marked reduction of temperature and recovery followed.

It seems actually probable that by means of an artificially wetted skin, the traveler in the desert can protect himself against that scourge of the desert, the simoon. There is no poison in the air, as the old books maintain, but just sand and a great air thirst. The air is heated and like a blast from a furnace desiccates. The simoon parches and shrivels; hence the traveler must keep his skin continually moist, or his body becomes heated above the critical temperature.

Will not some ingenious son of the West devise an evaporating mask and an automatic moistener for the traveler over the parched sands? The Arab kneeling and covering his face only half-way protects himself. He could add to his safety by using a damp towel.

With a full appreciation of the psychophysics of the problem we may nevertheless omit consideration of the effects of sunshine, skyshine, shade and the never-ceasing mutation of color, motion, form and sound prevailing outdoors, compared with the monotony of indoors, and come directly to the conclusion that the prime physical difference between fresh air, so-called, and foul air, lies in the water content or humidity, remembering that air thirst is a function of air motion.

The term relative humidity is widely used and little understood. In scientific words, it is the ratio of the pressure of the water vapor present to the pressure when space is saturated. It is a percentage and ordinarily 100 means extreme dampness, rain, fog or mist.

But even in physics, things are not always what they seem to be and relative humidity is no exception. We sometimes have rain when relative humidity is less than 100. What is more troublesome, relative humidity does not mean the same thing if the temperature varies. Thus two localities may be listed as having the same relative humidity but the actual dampness will not be the same. Asheville and Los Angeles have a mean relative humidity in January at 8 p. m. of 72 per cent; but at the former city the weight of the

# Radium and Its Works

## How the Alpha, Beta and Gamma Rays Are Being Applied in Commerce and in Medicine

By Ralph Howard

IN view of the fact that there is not a pound of radium in the world, it seems rather useless to point out what could be done with a ton of this precious mineral; and yet the fact remains interesting that, according to the late Sir William Ramsay, the energy in a ton of radium, if it could be harnessed to human uses, would propel a ship of 15,000 tons with engines of 15,000 horse-power at a speed of fifteen knots an hour continuously for thirty years. It now requires a million and a half tons of coal to accomplish the same result. Even with the present high price of coal, however, the standard method remains cheapest, since the market value of radium is $3,260,000 per ounce.

General interest in radium and its manifold uses has been revived recently by two occurrences in New York State. The first was the exhibition of three grams of the purified element, worth over $375,000, to New York and visiting physicians at the last annual meeting of the New York Medical Society, held in the Waldorf Astoria Hotel March 23rd-26th. The radium there dislayed was mined entirely from American carnotite deposits discovered in the Paradox Valley of Colorado and in the adjoining districts of Utah. The second was the appeal by a group of scientists to the New York Legislature to appropriate $250,000 for the purchase of two grams of radium, for use in the treatment of cancers, benign tumors, skin diseases and certain forms of tuberculosis.

Along commercial lines the development of radium is proceeding by leaps and bounds. Luminous paint manufactured with radium has long been used for making luminous watch faces, compass faces, and radiolated signs. It has recently been applied also to such daily utilities as hospital call buttons, automobile and motorcycle speedometers, airplane and ship instruments, telegraph dials, steam gages, and poison-bottle indicators. An interesting application has been the manufacture of fish bait where a dab of radium at the end of the hook takes the place of live or artificial bait.

Other uses of daily convenience as well as of commercial importance include: electric-switch push buttons, gasoline gages, mine signs, house numbers, pistol sights, crucifixes, toy doll and animal eyes, electric flash-light locators, theater-seat numbers, key-hole locators, bedroom slipper buttons, door and furniture locator buttons, automobile steering-wheel locks, safe-combination dials, etc.

The therapeutic value of radium has been confirmed and extended in the last few years by a more accurate classification of the effects of the three kinds of rays which radium emits in the process of disintegration. The alpha and the beta rays, it has been found, are the heaviest; at the same time that they have the most pronounced curative effect, they have also the least penetrative energy, so that their chief use is against exposed cancers and diseases of the skin. The gamma rays, on the other hand, are the lightest and possess the greatest penetrative energy; but their curative effect is least pronounced of all. "The gamma ray is in effect a highly penetrative type of X-ray. It is capable of penetrating about eleven inches of solid lead; and of course the human body obstructs it scarcely more than a pane of glass obstructs an ordinary ray of light."

Hence adequate treatment by physicians of superficial malignant growths is accomplished primarily by exposing them to the alpha and beta rays; with deep-seated cancers, the healthy tissue is protected from the alpha and beta rays by a metal screen through which, as well as through the body, the gamma rays penetrate with ease.

The principles by which radium effects its curative work are of notable interest. In the first place, just as certain tissues have a peculiar affinity for certain stains and an antipathy to others, so radium works selectively. It attacks the diseased tissue more quickly than the healthy. Furthermore, a certain amount of irradiation actually stimulates the diseased cells, and makes them grow more successfully; but when that point has been passed, the effect of the radium is to over-stimulate the cells, with the result that they die of a form of fatty degeneration or necrosis. Precisely what the explanation is for these curious phenomena has not yet been determined, and it remains true to this day that in certain malignant growths, all possible amounts of irradiation stimulate the growth instead of checking it. The backers of the radium bank are hopeful, however, that further experimentation will do much to clear these points up.

While the expectation has not been entirely abandoned that radium may some day completely take the place of surgery in the treatment of cancers and allied diseases, its present use is mainly in collaboration with operations. It has been found that the combination is particularly effective, surgery being used as far as possible, with radium as a pre-operative or post-operative aid. In the treatment of facial cancers, radium is exceptionally important, since it leaves no disfiguring scars, otherwise sometimes so horrible as to be worse than the disease itself.

### The Muscle as a Motor

To the Editor of the SCIENTIFIC AMERICAN:

I would be very glad to have some enlightenment on the following matter: What is known at present about the animal muscular system viewed as an apparatus to convert kinetic (chemical) energy into mechanical power? The ordinary encyclopedial works of reference, at least those with which I am acquainted, give only very vague information.

The points I should like to obtain clearness about are the following:

1. The muscle produces *power* by its alternate contraction against resistance and subsequent relaxation. The amount of the power thus produced is considerable; its ultimate source is evidently the slow oxidation of food constituents after their incorporation in the blood. Now what intermediate stages are interposed between both terminals? Are these *heat, electric current, magnetism* or what?

2. Is the muscle itself a *motor* in the mechanical sense? i.e. Is the conversion of kinetical energy into mechanical power effected within the muscle itself or in some other organ—in the cerebral or nervous system? It appears to me probable that the first is the case and that the nervous system merely plays the part of a transmission or gearing.

3. Is there any remote chance or possibility to *construct a muscle motor* from ordinary non-living materials? In other words, would it ever be feasible, of course not without much minute study by anatomists, physiologists, chemists and mechanical and electrical engineers, to construct an *engine* of which the original source of power would be the slow oxidation by atmospheric oxygen at low temperature of several organic compounds such as carbon hydrates, fats, albuminoids, alcohol, etc., and in which power should ultimately be obtained in the shape of a *contraction* and *relaxation* of a system of complicated *contractible elements* made to emulate the action of the animal muscle?

I find in the well-known work of Dr. Ranke (Der Mensch) the statement that in the human organism about 1/6 of the total amount of heat of combustion of the food can be recovered in the form of *external mechanical power*. If this be correct it is not a bad output for any motor and possibly several other animals, more specially designed to produce power (think of swallows, seagulls, carrier pigeons, etc.) would give a much higher percentage. As to *power* in comparison with *deadweight* the human motor certainly is no record, a fact which accounts for man not having been able until now to fly by his own muscular power. Of course as man and even the lower animals have many other functions besides those of a motor it is not to be expected that in any living organism the theoretical limit as to fuel economy or lightness should be reached.

I think however that the swallow or the seagull might prove on investigation to be *engines* both *lighter* and more *economical* than even our modern flying motors, and if this should prove to be the case there would be I think every inducement for the engineer to try to adopt their methods for the conversion of energy.

For any information on this matter I will be very thankful. N. C. UOOGVLIET.

42 van Galenstroat, The Hague, Holland.

### Cinders and Concrete

To the Editor of the SCIENTIFIC AMERICAN:

In the July 10th issue of your magazine a correspondent wrote of the danger of using "Cinder Concrete." I wish to add our experience, showing the positive folly of using cinder fill in the neighborhood of electrical conduits.

On account of new construction, it becomes necessary to remove a portion of the roof of one of the largest buildings in this city. In the original construction of this roof a six-inch layer of cinders had been laid on the conduits; then seven inches of concrete and finally several layers of roofing paper thoroughly tarred.

The conduits had remained in the cinders eight years only, and in many cases were entirely destroyed, leaving the wires exposed. It would have been impossible to renew or re-install any new wires in these conduits.

The remedy for this condition is to put a grouting of good concrete entirely surrounding the conduits, when the installation is made.

City Electrician, Omaha. ISRAEL LOVETT.

### A Problem in Electrical Engineering

To the Editor of the SCIENTIFIC AMERICAN:

Will some reader kindly advise on the following: I am having great trouble due to burnt-out coils of generators during heavy windstorms on the hills at an altitude of 6,000 feet. The plant consists of generators working at 5,000 volts and transmitting power over 3½ miles of copper to transformer house. The transformers are oil-cooled and inside the transformer house there is a bank of Wentz arresters with choking coils in the mains and grounds straight down to earth plates. These have been working for many years. There is no trouble at the transformer home end.

At the generator and aluminum electrolytic arresters are installed, also water arresters. That is a wire from each of the three conductors (3 phase) is taken down to the water to the three contacts with water and kept so far apart that no current flows. None of these devices are able to protect the machines.

Perhaps some one with experience of lightning could offer suggestions, which will be received with thanks. I would also say that grounded barbed wire has been run over the poles above the line.

Aruvankadu, India. BLUE GUM.

### Mosquito Larvae Killed by Foul Waters

To the Editor of the SCIENTIFIC AMERICAN:

My attention has been called to an article in the SCIENTIFIC AMERICAN of May 1, 1920, under the above title. From the context this would appear to relate to an article published by me in the Public Health Reports of August 8, 1919, and I am therefore taking the liberty of writing you about it, although I have not seen the entire article.

In the quotation from your article, sent to me, emphasis is laid on the observation that the larvæ of Anopheles mosquitoes do not thrive on foul, stagnant water. This statement, I believe, accords with the facts, but the title is apt to be misleading in giving the impression inadvertently that this may be the case with all mosquitoes, which is certainly not true. The more common mosquitoes—the so-called house mosquitoes, Culex and Aedes—flourish prolifically in foul, stagnant water and seem to thrive in proportion to the foulness of the water. This fact is very important in relation to anti-mosquito work in the northern states where Anopheles are relatively rare but the other mosquitoes are abundant. To circulate the impression in such districts that foul waters tend to inhibit mosquito breeding might do a considerable amount of damage.

In view of this possibility would it not be worth while to publish a note in the SCIENTIFIC AMERICAN calling attention to the fact that the above-noted observations apply only to Anopheles mosquitoes?

# Where Willow Ware Comes From

## How the Tree Is Grown and Tended to Yield the Raw Materials of Furniture and Basket Factories

By George H. Dacy

FROM an artistic standpoint, the graceful, willowy willow tree which nods and courtseys with the slightest wind has long been admired and complimented as an object of rare beauty. From a utilitarian viewpoint, the willow tree and its kith and kin are just as deserving of commercial acclaim. At present willow furniture is in keen demand, especially on account of its handsome appearance, durability and light weight. Furthermore, the national demand for high-grade willow baskets still holds firm. This domestic industry, which is centered in the neighborhood of Syracuse and Rochester, is chiefly in the hands of large dealers who buy willow from the producers—there being many commercial or willow farms in that section—and peddle them among specialized basket-makers who work at home and are paid a specified sum per dozen—according to size and quality—for the baskets which they turn out.

Forestry experts, versed in basket willow culture, recommend that novitiates restrict their plantings to such varieties as the American green and patent Lemley willows. These require a minimum of cultivation, are easy to peel and ordinarily are in demand on the domestic market at good prices. Under conditions where the cost of peeling is not excessive, the purple willow which yields quality material may also be produced profitably. On account of their large size, American green willows are easier to peel, while this work can be performed at a lower cost per pound than ordinarily obtains. On the average from 6 to 10 tons per acre is a fair yield for this variety although as high as 14 to 15 tons have been harvested under especially propitious conditions. This variety of willow is in demand by furniture makers and the dealers in willow baskets. Although it outranks all other willows produced in the country, it also involves a disadvantage in that it is susceptible to insect attacks and disease. However the willow-shoot sawfly, the stool borer and the leaf rust which attack the American green willows can be controlled although the expenses of such work often are prohibitive.

All basket willows are developed from cuttings from shoots or branches. None but the best stock obtainable should be used, as the plants under such conditions often will last 14 to 15 years. Cuttings usually are purchased by the thousand from reputable growers whose stock is free of disease. Many successful growers have started with 200 to 300 plants and gradually increased as they became more experienced in the business. Cuttings, ordinarily, are set out in the spring and are made about six weeks previous in order that they may callous over at both ends as cuttings which have healed in this manner will grow most rapidly. Care should be exercised against planting any diseased or damaged cuttings as almost invariably they will fail. Selected cuttings from the tall dominant shoots are the ones to plant. Cuttings from one-year-old shoots—10 to 12 inches long—may be set out on a well-prepared, drained, sandy loam soil. If the soil is not in good condition, it is preferable to use cuttings 12 to 18 inches long which are obtained from two-year-old shoots.

A pocket knife is generally used where only a few cuttings are desired, a pruner, a corn knife or a hatchet generally are used. Using ordinary orchard pruners, two men can cut, count and tie about 5,000 American green or 7,000 purple-willow cuttings in ten hours. By strapping one handle of the pruners to a bench in which a groove is cut to hold the lower jaw of the tool, one man can perform as much work as two. The cuttings can be tied in bundles and sawed but there is always danger of damaging them so that the tips will not callous properly, but instead will rot. There are also special machines on the market which the large commercial growers utilize.

Ordinarily the cuttings are set out early in the spring when the soil is moist, the weather cool and before the cuttings show much evidence of growth. A sharpened stick or iron rod from three-eighths to five-eighths of an inch in diameter and three feet long should be used to punch the hole in the soil wherein to set each cutting. Each cutting should protrude about two inches above the ground and should show one or two buds near the surface. Close spacing of the cuttings insures better yields and improved quality. Where the spacing is close, little trouble results from weeds as the plants usually choke them out. Close spacing, however, is disadvantageous in the case of the purple or Lemley varieties as after six or eight years it intensifies the tendency of these plants to die out. Hence on soils of average fertility, according to

(*Continued on page 235*)

1. Bundling the willow rods in the field, after they have been cut. 2. The cutting is done by hand, with a hooked knife. 3. Preparing cuttings for the planting of new patches of willows. 4. Storing the bundles in pits where they remain until the rods are cut up. 5. Peeling basket-willow rods, a slow and expensive hand process

**How the cuttings from which the crops of future years will come are prepared and tended by the modern willow-farmer**

All told there are more than 200 species of willows, a basket willow variety being one which produces long, straight rods suitable for basket-weaving activities. The Federal Forest Service has distributed thousands of willow cuttings to prospective growers in all parts of the country during recent years to the extent that enough successful plantings have obtained to show that the willow can be grown profitably in all sections of the country except where limited precipitation and high elevation obstruct its development. The basket willow demands plenty of moisture and hence it can be produced only in localities where the water table is not lower than from two to six feet below the grade line. A loose, sandy loam provides the best soil conditions while the experienced grower will always select an exposure where the wind has full sweep, where conditions do not favor insect attacks and the development of fungous diseases, where weeds are not rampant and which is located so that it can be worked economically.

## From Water Tower to Lofty Dwelling

ALL sorts of improvisions in the way of dwellings have been shown and described in these columns as the result of the world-wide interest in housing. We have the converted water tower to add to our published collection—an idea, by the way, which might well be applied wherever possible.

Somewhere in New York State there is a wealthy gentleman farmer who has made over his water tower into the lofty dwelling shown in the accompanying views. Using the sturdy wooden framing as a base for subsequent operations, he covered the structure with boards and metal lath, followed by a coat of cement. The tower has been capped with an attractive roof, as shown. A stairway winds about the tower on three sides, terminating at the top on one side of a wide balcony which commands a splendid view of the surrounding country.

Now the water tank, which supplies water pressure to the master's house and various other buildings about the property, has been left precisely where it was before, namely, at the top of the structure. However, it is now closed in on a level with the top balcony. Below the tank is a large bedroom, and below it a dressing room. The ground floor contains the pumping engine and other equipment, much the same as it was before the conversion. There is a flight of stairs inside, connecting the second and third floors, so that one does not have to go outside in passing from one floor to the other. Electric lights, running water, steam heat and other comforts are included in this odd dwelling which affords much pleasure to its owner.—By *Alfred Langville.*

## A Congressional House-Cleaning

IF cleanliness is next to godliness, as the old saw has it, then there would appear to be good authority for the poor repute in which our national legislative body is held in some quarters; for the fact is, the chamber in which the House of Representatives holds its sessions has not been cleaned save with broom and mop for the past ten years. This long period of neglect is now being brought to a termination, however, and the entire building occupied by the lower branch of Congress is having a thorough overhauling and cleaning. Our photograph shows the ladders and scaffolding erected for the use of the painters who are giving a new surface to the legislative chamber, and affords some indication that a thorough job of house-cleaning is being done.—By *Ralph Howard.*

## Traveling Derrick and Pile-Pulling Scow

MOST persons inspecting one of the mammoth ore docks at Two Harbors, Minnesota, and walking its entire length of more than one thousand feet, would have said that such a structure as this, containing more than 5,000,000 feet of timber, should certainly not be demolished. Yet that is what was done with two of the monster docks at that busy shipping point to make room for the new steel and concrete ore dock.

One of these docks was removed entirely; that is, the foundation piles were pulled and the foundation cribs and filling dredged out. The extent of these operations can be judged from the fact that the dock rose to a height of 56 feet, stretched out 1,054 feet, and had 170 pockets. The contractors found it necessary to use a traveling derrick with a 60-foot boom. This was carried on track rails laid on top of the dock. The structure was in such good condition that the work of wrecking it was extremely difficult, and called for many stout pulls. It was a striking example of the apparent waste in modern economy, when the old must make place for the new.

But if the wrecking of the superstructure was difficult the real tug of war came when the work was begun of pulling the long piles of white and Norway pine out of the stiff clay of the lake bottom. Some of these immense piles penetrated the clay more than twenty feet, and offered tremendous resistance. The powerful scow with its modern equipment was, however, equal to handling the work, as by means of lines leading over a heavy steel frame and two sets of five-sheave blocks it could exert a pull of 110 tons on the refractory piles and lift them from their resting places. Some idea of the extent of this undertaking can be gained from imagining that if all the piles that were yanked up out of the mud were spliced end to end to form a gigantic flag pole, then the flag would float at the rather perilous altitude of 20 miles in air.—By *George F. Paul.*

## The Yawing of Ships

IN the course of experiments on the rolling of model ships in which the models were held parallel to waves by a small constraining force, Dr. K. Suyehiro noticed that for a certain range in the period of the waves the model remained always in the same position, while for the other range of the period it had a strong tendency to yaw in one direction or the other, according to a writer in a British paper. When the model was released from constraint it was found that for a certain period of the waves it yawed so as to set itself parallel to the line of the crest and for another period perpendicular to it, just as may be noticed with a boat among waves, especially if it is riding on breaking rollers on a sea shore.

Dr. Suyehiro considers that this method is caused by the action of a gyrostatic couple due to the rotational motion in two different planes at right angles—namely, pitching and rolling; and in a paper before the Institution of Naval Architects he gave a mathematical solution of the problem on this assumption. He pointed out two consequences of the phenomenon. In the first place, when a ship rides on waves nearly synchronous to her natural period of rolling she will be directed square to the waves and relieved from heavy rolling if the period of the waves is a little shorter than her natural period, but will ultimately be exposed to waves abeam and subjected to heavy rolling if the period of the waves is a little longer. In the second place, when a small boat overtakes or is overtaken by a large ship the interaction between the two will be augmented by this yawing phenomenon because the small boat, as it approaches the region of the divergent waves formed by the large ship, will be set in oscillation, and it will be turned so as to lie parallel to the line of them. Hence, if it is not properly steered, the danger of collision will be increased.

## How the Stars, in Actual Size, Check Up When We Put Them Against the Sun as a Standard

By Professor Henry Norris Russell, Ph.D.

SINCE first men looked intelligently upon the starry skies, they have doubtless wondered what these shining specks might readily be—at first with the vague questioning of the child in the nursery rhyme, then, as knowledge grew, with gradually greater understanding. Everyone knows now that the stars are huge luminous masses, like the sun, at very great distances; more exact information shows us that if the stars were arranged in the order of their real brightness the sun would not be very far from the middle of the sequence—at least, of the portion known to us. The brightest star—not to our eyes, but in reality—of which we know is Rigel, in Orion, which is some twelve thousand times brighter than the sun; the faintest so far known is the feeble distant attendant of Alpha Centauri, which is a little less than one ten-thousandth as bright as the sun. Between these widely separated extremes we know of hundreds—nay, thousands—of stars of all degrees of luminosity.

But what of the real sizes of these remote bodies? If a star is brighter than the sun, is it also bigger? It may well so happen; but it is not necessarily the case, for if a star is hotter than the sun, and gives out more light per square mile of surface, it may exceed the sun in brightness even though it be somewhat smaller in diameter. Conversely, a star may be fainter than the sun and yet larger in size. The observed sequence of stars, arranged according to the amount of light which they give out, depends therefore in a rather complex fashion upon the interaction of these two factors. Can we hope to separate them, and so come to some knowledge of the true diameters of the stars at large?

In the rare cases of eclipsing double stars (variable stars of the so-called Algol type) we can obtain definite data regarding the relative size and brightness of the two stars of a pair; and in a very few instances spectroscopic data enable us to translate these into actual diameters in miles. In these instances the stars usually turn out to be bigger than the sun, but not very much bigger—five or six times the sun's diameter being exceptionally large.

But these few cases are hardly enough to trust as a fair sample of the stars in general, with their great variety of brightness and color. To go further, we must try to get some way of estimating how much light a star gives off from each square mile of surface—its surface-brightness.

### Optical Pyrometry Upon the Stars

It is a commonplace of experience that, as any solid body is heated hotter and hotter, it begins to shine, and shines more and more intensely, while at the same time the color of its light, at first dull red, becomes yellower, and at last white. The theory of radiation, which is now well developed, enables us to give numerical exactness to these qualitative impressions, and to estimate the temperature of any hot body from the color of the light which it gives off. Indeed, this "color-match" method of determining temperature is of sufficient accuracy to be of practical usefulness in some industries which employ highly heated furnaces. By an extension of the same principle, we may estimate the temperature, and also the surface-brightness, of a star, if only we know its color. To be sure, the stars are not solid bodies, but masses of gas; yet there is good reason to believe that this does not seriously vitiate the application of the theory. Several lines of attack are open. The simplest is afforded by the eclipsing variables already mentioned. Here in many cases we find systems composed of a large faint star and a smaller, but brighter, one which is eclipsed behind it. In these systems the large faint star is always found to be red, and the small bright one white. And, in general, the greater the difference in color, the greater also is that in surface-brightness.

Other methods of investigation lead to similar conclusions, and, though the data are still scanty, all are in tolerable agreement as to the degree in which surface-brightness varies with difference in the color of the star—or, for that matter, with the class of the star's spectrum, which is very intimately associated with the color of its light.

From the available data, it seems probable that the whitest and hottest stars, like those in the belt of Orion, give out about twenty times as much light per square mile as the sun does. Stars like Sirius, a step lower in temperature and color, may be of seven or eight times the sun's surface-brightness; and yellowish stars, like Procyon, twice as bright as the sun. Those resembling the sun in color and spectrum may be assumed to be similar also in surface-brightness; but orange stars, like Arcturus, are probably of about one-sixth the surface-brightness of the sun, while red stars like Antares may fall as low as one-thirtieth, or even lower.

### Big Stars—and Bigger Ones

Fortified with these estimates, we may proceed to figure out how big some of the familiar stars are. Let us begin with Scorpio—so well seen in the summer sky. The principal stars of this constellation are remote and very bright. All but Antares are also very white, and doubtless very hot. The brightest of these is Lambda Scorpio, at the end of the tail, which gives out about 1,500 times as much light as the sun. Being so white, we may estimate its surface-brightness as 15 to 20 times the sun's—which makes its area from 75 to 100 times that of the sun, and its diameter nine or ten times the sun's—taking round numbers. The other conspicuous stars of the constellation are a little fainter, and probably somewhat smaller; but all of them are probably several million miles in diameter. Antares, however, is an exception. It is enormously bright, giving out about 3,000 times the sun's light, and is also very red. Estimating its surface-brightness, correspondingly, as one-thirtieth the sun's, we reach the enormous area of 90,000 times the sun's, and a diameter 300 times that of the sun, or a quarter of a billion miles. Extraordinary as this result may seem—a star so huge that the whole orbit of the earth could be put inside it—it is hard to see what modifying factors could greatly alter the estimate; and of course such an object is very small indeed in comparison with the nebulæ, which are hundreds or thousands of times greater in diameter.

Of the other conspicuous summer stars, Arcturus is probably the biggest. It has a little over 120 times the sun's luminosity, probably some seven times its area, and roughly 25 times its diameter. Vega, which is a little nearer than Arcturus, and gives out about five-sixths as much light, is a white star, and its diameter works out about four times that of the sun. Altair is a relatively near neighbor of ours, and is actually only some eight times as bright as the sun, and probably three times as bright per square mile—which makes its diameter half as great again as the sun's. Procyon, which is a little fainter and a little yellower and cooler, is probably very much the same size as Altair. Sirius, some 25 times as bright as the sun, is white, and its probable diameter is twice the sun's. Rigel, which gives evidence of being hotter than Sirius, has perhaps ten times the sun's surface brightness, which would make its diameter 35 times that of the sun, but only about one-tenth that of Antares.

So the story goes. Of the stars which are conspicuous to the naked eye, some, which owe their apparent brightness to their proximity, are but little larger than the sun in actual diameter. Others, which are remote and of great real brightness, run much larger—especially the giant red stars; but there are probably very few that exceed the dimensions computed above for Antares.

To find stars smaller than the sun we must look among the faint members. Take for example the well-known double, 61 Cygni. The stars of this pair are about 1/20 and 1/40 as bright as the sun. They are also orange-red in color, and their surface-brightness may be estimated as 1/20 that of the sun, which makes the diameter of the brighter component about equal to the sun's, and that of the fainter three-quarters as great. Passing to still fainter objects, we may take Barnard's star—the second nearest in the heavens—which gives out 1/2,500 of the sun's light. This is an extremely red star, and its surface-brightness, on the basis of our previous estimates, would be perhaps 1/50 of the sun's. This would make its diameter about one-seventh of the sun's, or some 120,000 miles. There is some reason to believe that this is too small an estimate, and that these very faint stars give out even less light per square mile than we have suggested. None of these tiny stars, however, can be seen without a telescope, and hence our conclusion stands, that the stars visible without instrumental aid are for the most part of the size of the sun or larger, but that the large majority of them are less than ten times the diameter of the sun, while a very few run up to the size of the earth's orbit.

**NIGHT SKY: SEPTEMBER AND OCTOBER**

### The Heavens

Our map shows the appearance of the sky in the later part of the evening, when the summer constellations are nearly gone and those of winter are beginning to rise. Sagittarius, Ophiuchus and Bootes are setting. Hercules and Aquila are still in sight with Lyra above and between them and Cygnus still higher. Fomalhaut is the only conspicuous star in the south, and Pegasus and Cetus are the principal constellations in the southeast. Andromeda, Perseus and Aries are well up in the east and northeast, while Taurus and Auriga are rising. The Great Bear is low in the north; Draco and Ursa Minor are above, and Cassiopeia and Cepheus still higher.

### The Planets

Mercury is in conjunction with the sun on the 8th, and becomes an evening star; but he is practically invisible until the end of the month, when he sets three-quarters of an hour later than the sun, and can be seen in the twilight, though not so well as next month.

Venus is also an evening star, and is gradually becoming more conspicuous. At the end of the month she sets half an hour later than Mercury, and should

# UNDARK

## Radium Luminous Material

## *"I want that on mine"*

If the gasoline gauge on your car has an UNDARK dial, you can easily see it in the darkest spot of road or garage without the nuisance of carrying a portable light, or, what is most common, tempting fate with a lighted match.

UNDARK is a factor for safety and service wherever it is used. It will make your car's gauges give the same 24-hour sight service that UNDARK gives to watch dials.

Such automobiles as Pierce-Arrow, Kissel Car, Stevens-Duryea, Lincoln, and others have UNDARK on gasoline gauges as standard equipment.

### UNDARK doesn't get dark in the dark

It contains real radium, the most precious of all minerals. UNDARK keeps glowing for years.

We are miners and refiners of radium-bearing ore, the pioneer manufacturers of radium luminous material in this country, and the largest in the world.

If you are interested in seeing how UNDARK can be applied, we will send you a TRY-OUT set for $3.00. We can also give you the names of manufacturers who use UNDARK on the particular articles in which you are interested.

*UNDARK can be successfully applied by manufacturers in their own plants. It is a simple process. We will instruct operators and organize the work for you. Write for details.*

**UNDARK is used on numerous articles, of which the following are the most important**

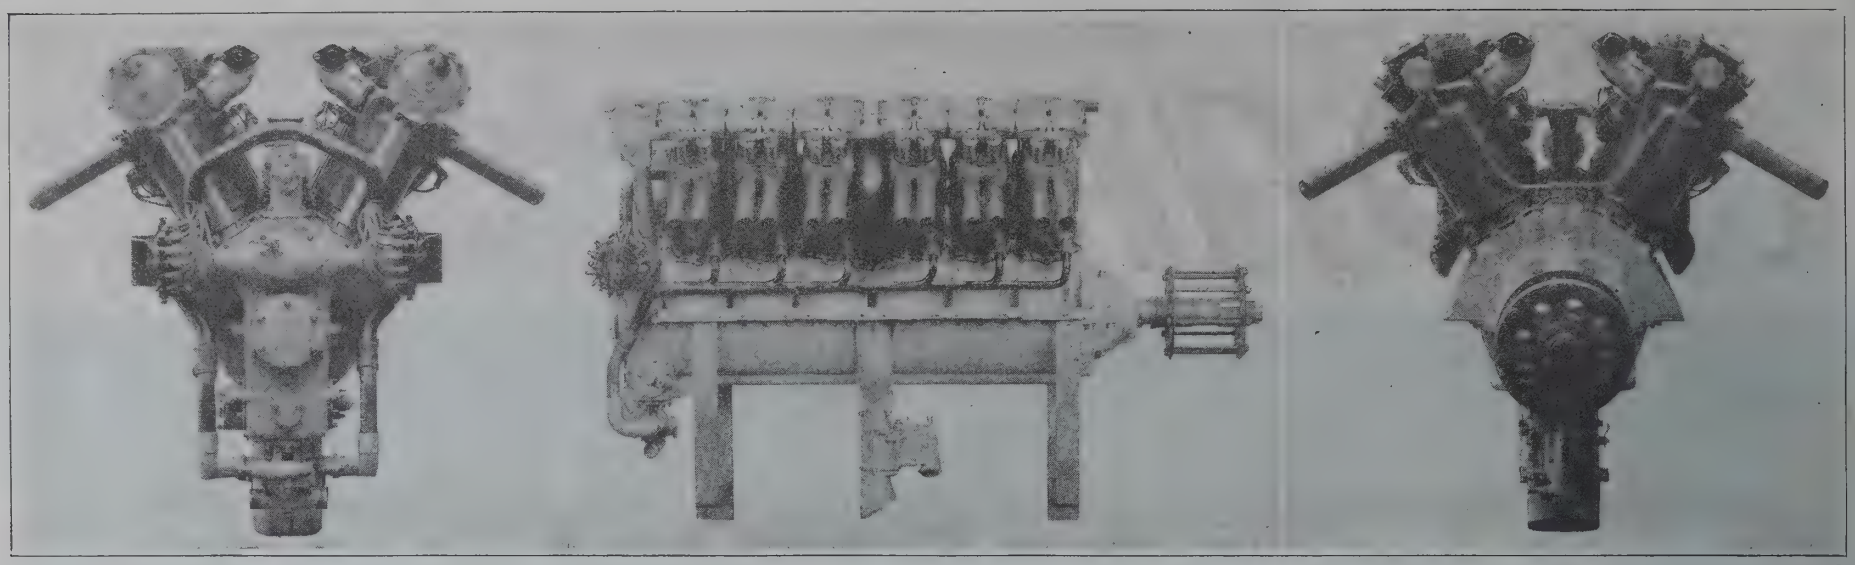
| | |
|---|---|
| Watches | Gasoline Gauges |
| Clocks | Speedometers |
| Flashlights | Steam and Pressure Gauges |
| Pull-Chain Pendants | Revolver Sights |
| Push-Button Switches | Telephone Mouthpiece |
| Flip Switches | Fire Extinguishers |
| Door Bells | Mine Signs |
| House Numbers | Women's Felt Slippers |
| Hospital Call Bells | Fish Bait |
| Ship's Compasses | Theatre Seat Numbers |
| Locks | Convention Buttons |
| Safe Combinations | Poison Indicators |

**Names of the makers of these furnished upon request**

**Radium Luminous Material Corporation, 58 Pine St., New York City**

**Factories: Orange, N. J. Mines: Colorado and Utah**

Trade Mark Name UNDARK Reg. Applied for



*Left:* Rear view of engine, showing the accessibility of the water pump at the rear of and below the crank case. *Center:* Right side of engine. Note the single duplex carburetor, set below and outside the crank case. This constitutes the outstanding feature of the design. This not only makes the engine fire proof so far as the carburetor is concerned, but solves the problems of synchronizing throttle and altitude control and saves weight. *Right:* Front view of engine. The included angle of the cylinder groups is 60 degrees. The individual type of cylinders, which provide the best water circulation and thus keep the cylinders cool and avoid valve trouble, are used

**Three views of the engine recently designed by Col. Jesse G. Vincent, which incorporates several novel features and gives remarkable results for its weight**

## A Forward Step in American Airplane Engines

**By Col. Jesse G. Vincent**

IT needs but a superficial study of present-day airplane design to convince even the uninitiated that the airplane of the future will be larger, have greater load capacity and more radius than the planes we have today. In order to accomplish this larger engines will be required or else the power plant must be divided among many small units.

It is an engineering axiom that a few large engines will generate a certain number of horse-power more efficiently than a greater number of small engines. There is also a greater degree of reliability to be secured with the larger engine, since it is possible for the same weight per horse-power to design parts with a greater factor of safety and small flaws and imperfections are less liable to interfere seriously with the strength of the larger parts.

It is evident then, that the evolution of the airplane will closely follow the development of the engine. It was at first thought that the air propeller placed a definite limitation on the possible size of an airplane engine. This limitation undoubtedly still exists, but engine design has not yet been definitely affected by this factor.

Good engineering practice requires that a design be based on certain practical and theoretical conclusions and it therefore follows that a new engine design must be based on the experience gained with engines which are comparable in size and general design with the proposed engine. With the great amount of experience gained with the Liberty motor at my disposal and also after study of the performances of all the best foreign engines, I undertook the design of this engine having about 25 per cent greater displacement than the Liberty with perfect confidence that the engine would prove fully as efficient and reliable as the Liberty and in addition would have features which experience had demonstrated were desirable.

The carburetor arrangement called for the principal departure from previous designs, and tests which have been made on the ground and in the air have demonstrated the desirability of this design from every standpoint. A single duplex carburetor is bolted to the underside of the lower half of the crankcase and the intake passages are cast integral with the upper and lower halves of the crankcase. Suitable manifold extensions serve to connect the cylinders and passages.

This arrangement presents many advantages. Firstly, it locates the carburetor in a low position in the plane which permits of a gravity fuel system, the simplest and most positive method of insuring a constant supply of fuel to the carburetor, eliminating the complication and added weight of fuel pumps, piping, valves, etc.

Secondly, the carburetor air-intake is allowed to project through the lower cowling of the fuselage and in this manner all fire hazard due to a back-fire is removed, it being noted that all gasoline vents discharge into the air-intake so that gasoline leaks within the cowling are absolutely prevented. This makes the airplane entirely fireproof for all civil uses.

The third advantage in connection with the use of a single carbureter is that a single adjustment suffices for the whcle engine. In previous large engines it had been the practice to employ as many as four separate carburetors and it was practically impossible to make the idling, running and altitude adjustments the same for all cylinders.

It is interesting to note that this carburetor is probably one of the largest built and is capable of handling sixty gallons of gasoline every hour!

(*Continued on page 236*)

## This Year's Nominations for the Hall of Fame

THE ballot for the fifth quinquennial election of the Hall of Fame has already been to the board of 102 electors and votes for the various candidates on the ballot will be received by the Senate of New York University until October 15. Announcement will be made on November 1 of the names that have been chosen by the electors for inscription in the Hall. The names of 68 men and 4 women who have not been candidates in previous Hall of Fame elections appear on this year's ballot, as well as several score of other names that have been voted upon in former elections but which failed to receive a sufficient number of votes to elect.

There are 11 inventors and 10 scientists whose names will be voted upon this year. Of the 11 inventors 5 are new nominations: Ottmar Mergenthaler, inventor of the linotype machine; William Austin Burt, inventor of the solar compass, the equatorial sextant compass and a very early typewriter; Stockton Barton, inventor of sewing machine devices; Robert L. Stevens, inventor of engineering devices; and Walter Hunt, nominated as the real inventor of the sewing machine. The 6 inventors whose names were acted upon in previous elections but who did not receive the number of votes necessary to elect but obtained a sufficient number to place them upon the ballot again this year are Charles Goodyear, Richard Marsh Hoe, Cyrus Hall McCormick, John Ericsson, Robert McCormick, and George Henry Corliss.

Walter Hunt, nominated by his grandson as the "real inventor of the sewing machine," is perhaps the most interesting of the new nominations for the reason that five years ago Elias Howe was elected to the Hall of Fame as the inventor of the sewing machine and Howe's name has already been inscribed on a

# FORD ECONOMY

## *How Gargoyle Mobiloil "E" reduces friction-heat, carbon and wear*

WHEN a Ford owner turns to Gargoyle Mobiloil "E" he nearly always gets one of the big surprises of his motoring experience.

He finds that engine overheating—excess carbon forming—spark plugs fouling—excessive gasoline and oil consumption—excessive friction and wear, are all unnecessary.

He finds that the Ford high-speed conditions *need* not invite frequent overheating.

He finds that he never before really knew how little carbon need accumulate in a Ford engine.

He finds that previous fuel and oil consumption were unnecessarily high.

He finds that frequent repairs and replacements of worn parts are no longer necessary.

He secures new power, especially noticeable on the hills.

The ability of Gargoyle Mobiloil "E" to reach all moving parts is due to its scientifically correct *body*. Its ability to absorb and radiate heat and give full protection to the frictional surfaces is due both to its high *quality* and to its correct *body* and *character*.

This means full protection—particularly vital to a Ford when low gear is in frequent use.

Combustion heat plus excessive friction heat causes overheating of the engine, boiling and evaporation of water from the radiator and unnecessary wear of the moving parts. Water is cheap. Repairs and replacements are not. Ford economy—great under all conditions—is made even greater through the year around use of Gargoyle Mobiloil "E".

This has been demonstrated repeatedly in all parts of the world. It is being proved daily all over the United States—*perhaps today by your next-door neighbor!*

With your oil reservoir emptied and refilled with Gargoyle Mobiloil "E", your engine will give you quick and ample evidence.

Write today to our nearest branch for a copy of our booklet, "Your Ford—Four Economies in its Operation." It gives the vital facts in regard to Ford lubrication.

# Smothering Fire with Bubbles of Gas

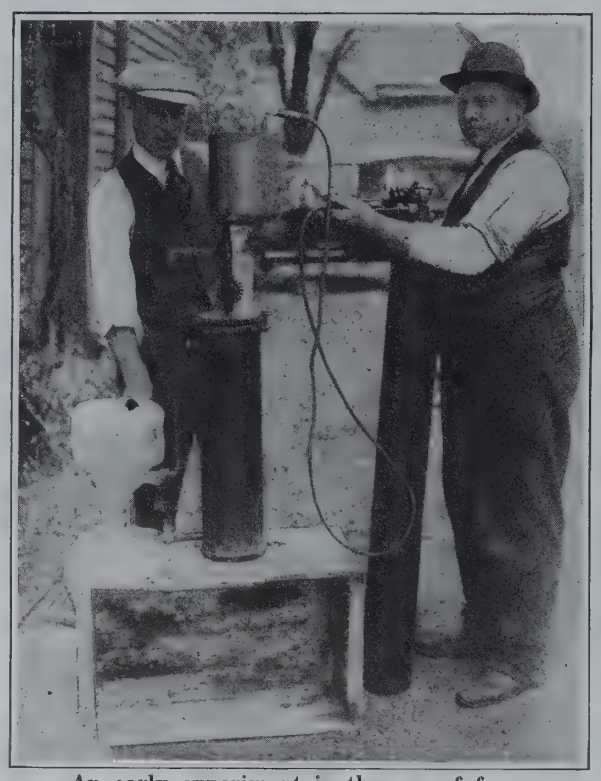
## How Carbon Dioxide Protects the Oil Tank Against Its Greatest Hazard

By J. F. Springer

STORAGE is a necessity in the business of producing petroleum. The problem of providing it is a gigantic one because of the vast quantities of oil that must be put into reservoirs and because of the excessive liability to destruction by fire. A typical oil reservoir will be, say, a circular steel tank having a capacity of 50,000 gallons. In an active oil field, such tanks may cover the visible landscape. Some day, suddenly, a lightning stroke will start oil in one of the tanks to burning. Under ordinary circumstances all the oil of this tank will be consumed in the conflagration and the owners will be content if only the fire does not spread. Only indifferent success seems to have attended the use of water and other liquids in respect to the extinction of a flame once started on the surface of a large body of oil. Petroleum is exceedingly combustible, being made up almost entirely of hydrogen and carbon in compounds tremendously eager to split up and give the constituent elements to any free oxygen in the neighborhood. Water acts by smothering combustion through preventing the access of the oxygen in the atmosphere. Other liquids either act similarly or produce gaseous material which performs the smothering operation. The problem of extinguishing the fire consists in getting the liquid or gaseous blanket all over the flaming surface.

But a new thought occurred to an American inventor some years ago when the century was young. This is the *foam* or the *suds* idea. Mr. Elmer Gates noted that if a given weight of fire-extinguishing liquid was first converted into a lather, the effect upon the flame is multiplied over what it would have been if used in the ordinary way. The greatly increased bulk of the liquid when converted into froth enabled it to screen the air, therefore the oxygen, from the surface on to which the fire-extinguishing material might be thrown. Over and above the foregoing idea was another entertained by the same inventor. He saw that if the bubbles of froth should themselves contain instead of air some other gas which was a non-supporter of combustion, the effectiveness of the suds would be enhanced. As the bubbles burst, their gaseous contents mingle with the air in the immediate vicinity and thus render it a less active supporter of combustion. Such gases as nitrogen, ammonia, carbon dioxide, are suited for the filling of bubbles. A gas of this kind may be very quickly mixed with the liquid from which the suds is made and a very large amount of the foam brought into existence. He considered that the bubble-like lather should contain inorganic salts of such character that upon heating they would decompose and evolve incombustible gases.

Here, apparently, we have the origin of the process which has subsequently been developed and utilized for the extinction of petroleum conflagrations and great and small fires of a more ordinary character. Mr. Gates' patent was issued January 12, 1904. He specifies for a suitable mixture a thick solution of ammonium soap. This may contain, for example, dissolved borax or ammonium sulfate. This solution, when ejected from a suitable nozzle, by pressure of a non-combustible gas, constituted his foam jet for the extinction of fires—the ancestor of the present successful means of using bubbles.



**An early experiment in the use of foam extinguishers**

Germany seems to have been the scene of the next developments. The early method took no account of the difficulty of forcing foam through conduits. Besides, it rather assumed that the mixture was already prepared. Consequently, with provision for maintaining separately the liquids to be mixed and effecting their mixture only at the time of use and close to the point of use, important advances were made. The older method was adapted to small hand apparatus. In the case of a petroleum tank, where large masses of foam were needed quickly on the surface of the oil, difficulties were encountered. These related particularly to the fact that with the older method the foam was forced through long conduits. During its passage, it was more or less subject to reconversion into liquid. Besides, the gas pressure behind it was somewhat liable to be impaired when the foam reached the tank. The improvements, due apparently to Herr Ernst Bartels, consisted principally in forcing two liquids through separate conduits to the immediate vicinity of the oil surface and there mixing them. A mixing chamber was provided; and from it the foam generated by the chemical reactions set up by the conjunction of the two liquids was ejected on to the oil. The Bartels English Patent was issued October 5, 1911.

In the meantime a United States patent was issued to certain officers of the Standard Oil Company of California for a system using two liquids of such composition that, when brought together, the gas carbon dioxide would be generated. This patent was issued February 21, 1911. About this time the United States Navy became concerned over the question of extinguishing fires on board oil-burning ships. A special board after deliberation recommended the use of the foam system. At Bayonne, N. J., on the border of New York Harbor, a tank 16 x 4 feet in area was filled to the depth of 5 inches with naphtha and set on fire. The flames rose to a height of twenty feet. But an application of a fire-extinguishing suds put the fire out in a few minutes. The liquids employed upon this occasion were probably formed more or less in accordance with the following recipes, the figures referring to parts by weight. Liquid No. 1: Glue, 1; glucose, ½; sodium bicarbonate, 7½; salicylic acid, ¼; water, 100. Liquid No. 2: Aluminum sulfate, 10; water, 100. The aluminum sulfate [$Al_2(SO_4)_3$] and the sodium bicarbonate ($NaHCO_3$) react upon each other and evolve carbon dioxide ($CO_2$). The foam is readily produced because of the presence of the glue and glucose. The salicylic acid acts as a preservative of the glucose. The glucose has an additional duty, that of stabilizer. In liquid No. 2 sulfuric acid was tried as stabilizer, but its corrosive effect on the container was objectionable. The volume of foam is eight times that of the combined liquids.

It is, naturally, very necessary that a good suds be made. Of the substances used for this purpose, an extract of licorice root is apparently one of the best. It was mentioned in this connection as far back as 1906 in the provisional application of Prof. A. G. Laurent of St. Petersburg, for an English patent. The most modern development of the foam system also employs it. Thus, the following percentages (again by weight) represent a pair of mixtures which are up to date, the "suds material" being a secondary extract of licorice root. Solution No. 1: Aluminum sulfate, 11; water 89. Solution No. 2: Suds material, 3; sodium bicarbonate, 8; water, 89. It will be noted that we have here an acid and an alkaline solution. The suds material is here put with the latter. Upon being mixed, the volume is increased to about ten times that of the original total. The bubbles will be fine and tenacious and will be filled with carbon dioxide. Moreover, the whole will flow well. The chemical reaction between the aluminum sulfate and the sodium bicarbonate is as follows:

$$Al_2(SO_4)_3 + 6\,NaHCO_3 = 3Na_2SO_4 + AL_2(OH)_6 + 6CO_2$$

When the bubble mass has done its work, the carbon

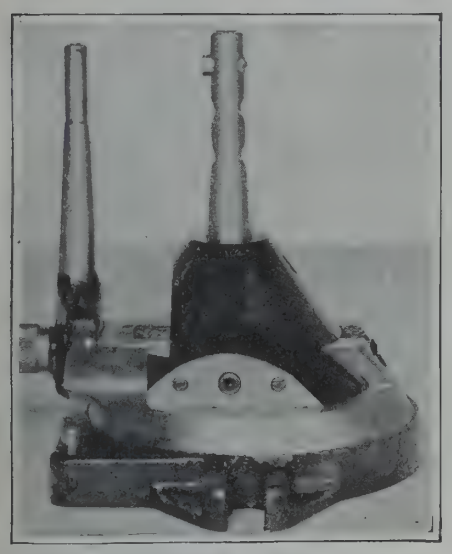
# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*



**This device dresses grinding wheels accurately and quickly**

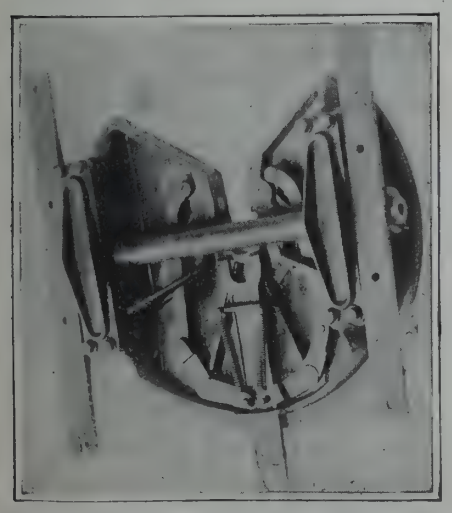
## An Accurate Grinding-Wheel Dresser

A NEW tool for dressing abrasive wheels with radial or angular faces has been introduced by a Detroit manufacturer. This tool will dress a 12-inch wheel to a radius of from 0 to 1¼ inch, either convex or concave, and to any angle desired. The tool post has three splines so the diamond may be set at right angles with the travel of the side for dressing angles. It also has 2-inch center height adjustment. When the distance from the back of the measuring post to the pivot center is known to be 3 inches then it is only a matter of addition or subtraction to obtain the required convex or concave curve.

## An Automatic Trailer Connection Device

A DEVICE for automatically coupling a trailer with a motor truck is a new product of a Massachusetts manufacturer. By using this device it is not necessary to use jacks to make the connection. As the tractor vehicle backs into the trailer a cam formed by the rear end of the device sliding down raises the trailer and continued backing couples it automatically.

When disconnecting the wheels of the trailer are blocked and a horse is placed under it. As a lever near the driver's seat is pulled the truck is disengaged from the coupling and enabled to move away from the trailer.

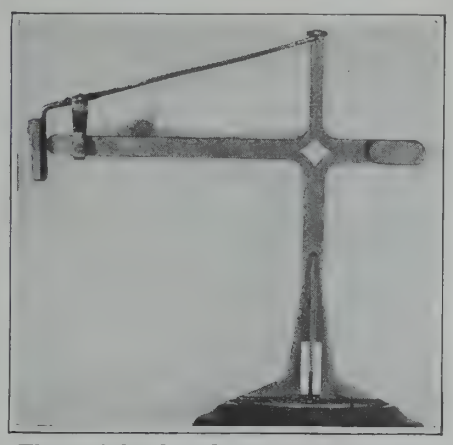


**This device for coupling trailer and truck does away with jacks**

## Is the Phonograph Fast or Slow?

SINCE the pitch of any photograph changes with the speed of operation, it is obvious that proper results can be had only when the correct speed obtains. Most phonographs are equipped with devices of one form or another to indicate the speed of the turntable, but in many instances these devices are not accurate. It is necessary to have recourse to some other method, such as counting the turns per minute, in order to check up the speed.

Among recent phonograph inventions is a speed indicator, which is shown in the accompanying illustration. This device consists of a small base which fits over the pin on the phonograph turntable, a standard, and a pivoted and weighted arm which serves as the indicator. The device is placed on a phonograph record which is to be played. As the turntable reaches its set speed,



**The weighted and pivoted arm indicates the speed of the phonograph**

a little weight at the end of the pivoted arm is thrown outward by the centrifugal force. The extent of this movement is indicated by the other end of the arm, which passes over a scale on the standard. The scale is of such simplicity that it can be readily read while the device is whirling around.

## Speeding Up the Rowboat with Paddlewheels

EVERY so often someone comes forth with a scheme for placing paddlewheels on a rowboat. This time it is an Englishman, who has been making small boats fitted with paddlewheels, as shown in the accompanying illustration. The paddlewheels are turned by means of cranks, and it is said that this method of propulsion has met with much favor at English summer resorts.

## New Cold Process for Vulcanizing Rubber

IT is reported that a very important discovery of a new process of vulcanizing rubber has been made by Professor Peachey of the Manchester (England) College of Technology. Laboratory experiments prove that the process will have far-reaching effects on the rubber-manufacturing industry. The importance of the discovery is in the fact that it is a method of cold vulcanizing. It makes use of two gases, sulfretted hydrogen and sulfur dioxide, which react on each other to produce water and free sulfur. The professor has found that when crude rubber, either in a solid form or in solution, is treated with these two gases the sulfur produced by their interaction vulcanizes the rubber. If the rubber be mixed with a waste material such as sawdust or leather scraps or paper, and the mixture is vulcanized, the resultant materials will serve a variety of useful purposes.

## A New Bar Straigtening Machine

A MACHINE for straightening bar stock up to 2 inches in diameter has lately been introduced by an Illinois manufacturer. V-blocks support the work while it is being acted upon by the screw. When the screw is elevated two sets of spring-actuated rolls lift the bars above the Vs so that it may be easily rotated.

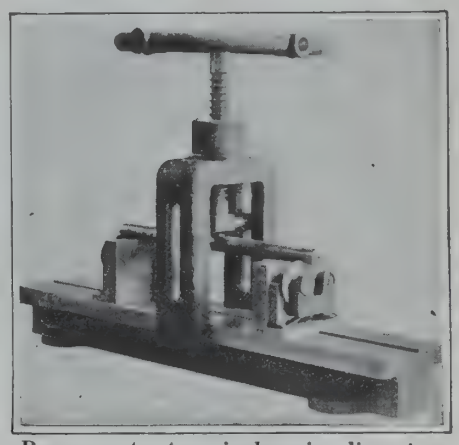
## A Washing Block for the One-Armed Man

THERE are some things that a one-armed man can do for himself with no trouble and with no special apparatus. There are other things, doubtless, that he can't do for himself, with all the trouble in the world and all the ingenious devices that might be brought to bear on the problem. But between the two extremes there are a great many things that he can do for himself with the aid of a little patience and a little ingenuity; and one of these concerns the washing of his lone hand and arm. The cleansing of other parts of his anatomy presents no special problem; but how to wash a hand effectively with no other hand to conduct the operation is not immediately clear. A German inventor has made it clear, however, with the little apparatus which we illustrate.

The curved inner surface of the wooden block which constitutes the

**England is having much fun these days with paddlewheel rowboats**

foundation of the device is cut approximately to the shape and size of the human arm. It is lined at different points with several fabrics of different degrees of harshness and softness, and with a coarse brush so that it is ready for any kind of a scrubbing job from axle-grease to the mere dead skin and excretions of the night. On its short upright it carries a finer brush for the knuckles; on its outer face it presents a bit of abrasive cloth for the filing of the finger nails; and at the top of the long arm is found a nail-cleaner which, in distinction from its prototype in ordinary use, is held stationary while the nail of the user is drawn about it. Finally, it holds a towel, securely fastened at both ends. With this outfit the one-armed man is able to complete his toilet so far as it refers to his hand and arm, and to maintain himself on an equal basis of cleanliness with any of his more fortunate two-armed brethren.



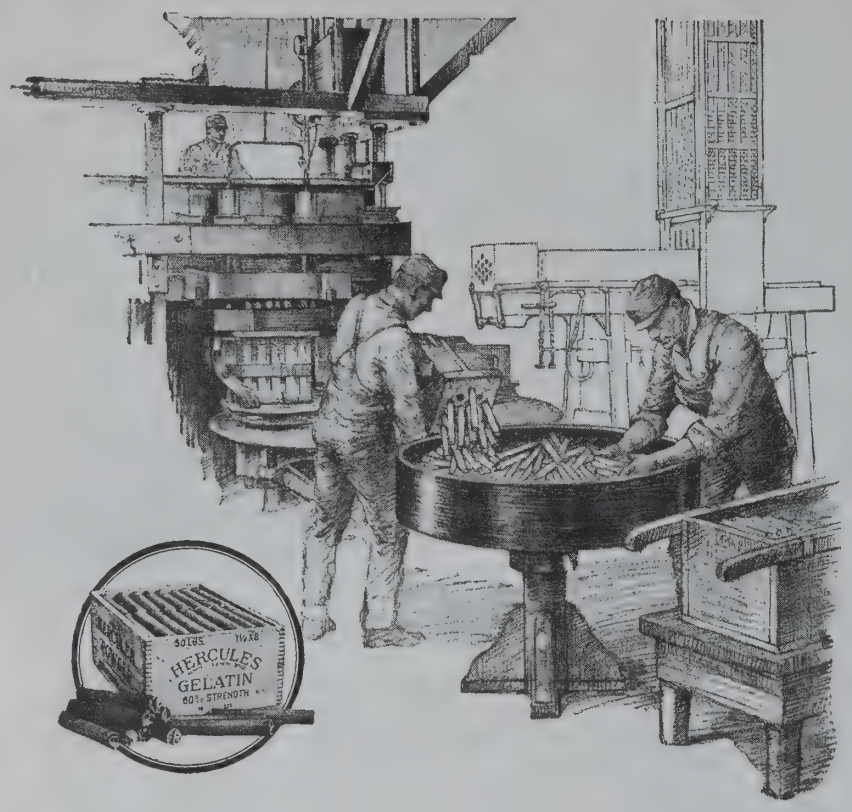
**Bars up to two inches in diameter can be straightened with this device**

## Latest Patent Decisions

**Commercial Success as a Measure of Utility:**—This is a suit in equity by the Whitlock Coil Pipe Co. against the Mayo Radiator Co. The decree herein is for the defendant. The pleadings raised the issue of non-infringement and invalidity. The patent refers to the invention as an apparatus for effecting the cooling of one fluid by the application of another and cooler fluid, such as the cooling of air by water, or of water by air—the condensation of steam by either air or water. In the patent, the patentee says: "That portion of the apparatus to which my invention relates, in common with other and similar apparatus, comprises a series of air tubes surrounded with water passages forming part of a water circulating system, by which the water which has become heated by its contact with the cylinder will lose its heat, and by its contact with the air tubes, through which, in order to increase the efficiency of the apparatus, the currents of air are caused to move." The plaintiff sues on all the claims of the patent. The court holds that there has never been made, with any commercial success, a structure which conforms to the specifications and claims in suit. It would be unfair to claim that the defendant's device infringes the plaintiff's device when the latter has added no substantial value to the art. To sustain the claim of the infringement would be to interpret the language of the claim as broad enough to

(*Continued on page 238*)

**With this device the one-armed man can wash, and wash clean**



# It's the Man That Counts

The human element probably plays a more important part in the making of explosives than in any other manufacturing process conducted on a large scale. There are no machines in the twelve great Hercules plants that need only to be started at the beginning of a day, stopped at the end, and which in the meantime carry out their tasks without attention.

Every machine used in the making of Hercules Explosives has a man for its master. Every motion it makes is watched. The results of its work are carefully checked. Nothing is ever taken for granted. No machine is looked upon as infallible.

In the gelatin packing house, for example, is a large machine which fills paper cartridges with *Hercules Gelatin Dynamite. Although this machine works with almost positive precision and accuracy, every cartridge which comes from it is inspected *twice* to make certain that it is properly packed. One inspection takes place immediately after the cartridge leaves the machine. Another before it is finally boxed for shipment.

The men who use Hercules Explosives know how dependable are the men who *make* Hercules Explosives. The Explosives themselves tell the story. Their power never fails those who seek its aid. In metal mine and stone quarry, at the bottoms of deep rivers and in the hearts of great mountains, where the engineer builds a city skyscraper and where the farmer blasts a ditch, Hercules Explosives live up to the name they bear.

**HERCULES POWDER CO.**

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farming Implements, Etc.*

### Pertaining to Aeronautics

AERIAL BOMB.—G. E. COOK, 45 Tehama St., Brooklyn, N. Y. This bomb is particularly designed to be dropped from an airplane, dirigible or other aircraft, and to explode on striking an object. It consists of a body provided with a large number of explosive shells containing shrapnel or the like, which shells explode before reaching the ground, thus rendering the bomb exceedingly destructive.

### Pertaining to Apparel

WAISTBAND.—BERTHA CLARK, 342 50th St., Brooklyn, N. Y. This improved waistband for skirts, petticoats and similar garments is arranged to enable a dressmaker to readily lengthen or shorten the waistband to suit the waist size of the garment on which it is to be used. Another object is to permit of stiffening the band after attachment to prevent the waistband from crumpling when the garment is used.

FASTENER.—J. P. BURKE, Box 125, Struthers, Ohio. The present invention comprises a fastener of ball and socket type especially adapted for use on garments. The device is made up in whole, or for its major portion, of wire. It possesses the advantage that it can be made very small and inconspicuous and it may be rendered practically invisible when colored to suit the fabric to which it is applied.

SHIRT.—H. H. HERST, Ocean View, Va. Mr. Herst's invention relates more particularly to men's outer shirts, and its object is to provide a novel construction in connection with the front portion of the shirt to conceal and hold the flowing ends of four-in-hand ties. The upper and inner portions of the front of the shirt are cut away to form a V-shaped outlet, and special provision is made to insure the retention of the shape of this outlet in laundering.

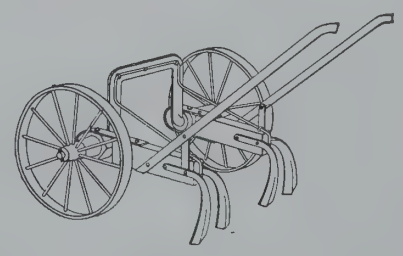
### Electrical Devices

THERMAL CIRCUIT CLOSER. — C. E. WIREN, 1637 61st St., Brooklyn, N. Y. An object of the invention is to design a bearing and journal indicating and protecting device capable of warning against continuing the operation of a bearing of machinery when said bearing is nearing the danger point of over-heating and approaching the point of destruction due to lack of lubrication. The invention provides means for closing an electrical circuit adapted to ring a bell or light an electric bulb light to warn against continued operation.

POWER GENERATING SYSTEM.—G. YANACOPOULOS, 541 E. 169th St., New York, N. Y. This invention relates to a power generating system and has for an object the provision of a construction wherein wind is utilized for compressing air to act as motive power for producing electrical current or for other purposes. A further object is the provision of a system whereby electrical energy may be produced and stored, the power necessary for the production being secured through a system of related machines for converting the power of the wind into a driving member for the generating dynamo.

### Of Interest to Farmers

CULTIVATOR.—H. C. SMITH, Clintonville, Conn. This invention relates to cultivators and has for an object the provision of a cultivator in which the cultivating members are resiliently held at a definite distance from



A PERSPECTIVE VIEW OF THE CULTIVATOR

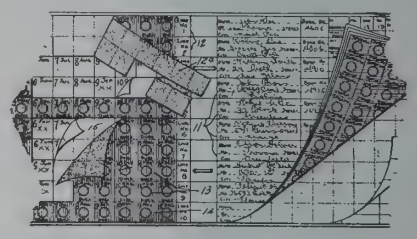
the row of vegetables being cultivated, this distance being easily varied, the resilient means consisting of a spring mounted on an arched axle having integral arms extending downwardly and rearwardly.

CULTIVATOR.—R. L. GUTHRIE, R. 3, Box 409, Santa Rosa, Cal. More particularly this invention relates to cultivators of the wheeled type, an object being to provide a cultivator which will be capable of a wide range of adjustment and which is relatively light so as to be easily moved over the ground. A further object is to provide a cultivator which may be utilized either as a pulling or pushing device, and which permits the plow standards and adjacent parts to be swung up out of the way and suspended on the handle.

FARM GATE.—T. HOUSTON, 202 Citizens Bank Bldg., Kokomo, Ind. The purpose of this invention is to provide a simple and inexpensive farm gate having means for holding one end of the gate in suspension, such means being adjustable to vary the height of the gate so as to permit the ready opening thereof under adverse conditions, such as when snow accumulates beneath the gate.

### Of General Interest

ACCOUNT BOOK.—A. HEISTERKAMP, 517 Garden St., Hoboken, N. J. This account book is particularly adapted for the use of societies and other organizations to enable inexperienced persons to keep an accurate record of all transactions. On one page are entered the names and addresses of members

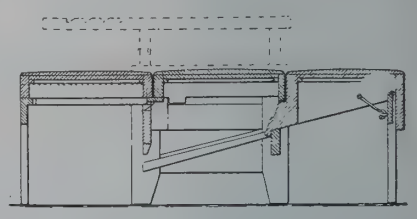


AN ACCOUNT BOOK FOR SOCIETIES AND ORGANIZATIONS

and on the opposite page, similarly ruled, are numbered spaces divided by perforations into series of stamps. Below this page is a wax page representing periods when dues to the organization are to be paid. As the dues are paid, the stamps are removed and pasted in a pass-book of the member.

IRONING SUPPORT.—S. E. DURANT, 176 W. 137th St., New York, N. Y. The object of the invention is to provide an ironing support more especially designed for ironing or pressing open-ended neckties, scarfs and similar neckwear, and arranged to permit convenient insertion of the support into either end of the neckwear to hold the same in propor position for an effective ironing or pressing.

CHAIR BED.—W. E. ESLHENBRENNER, 440 E. 143rd St., New York, N. Y. The invention provides an arm chair of the type commonly known as the Morris chair. The adjustable back which may be lowered into alinement with the chair



CHAIR CONVERTED INTO A BED

seat has a section under the seat which may be drawn out into alinement with the seat thus converting the chair into a bed of comfortable length.

PIGMENT-POWDER FOR MAKING SMEAR-PROOF IMPRESSIONS.—S. M. MCMURRAY, 54 Arcade, Nashville, Tenn. The object of the invention is to provide a pigment powder to be used in connection with an ink, such as printers' ink, or stamp pad ink, to bring out or intensify the impression made with the ink and also to render the impression resistant to the action of gasoline.

CUTTING BLOCK.—C. F. CONNOR, 23 Florence St., Marlboro, Mass. The invention pertains more particularly to a method of securing the several sections of a cutting block together. The prime object is to provide side and end bars by which the several parts making up the block may be securely clamped together, each of the bars being provided with nuts by which the bars are tightened into place.

FISH AND CRAB TRAP.—C. W. MUELLER, 1094 Summit Ave., Jersey City, N. J. An object of the invention is to provide a collapsible form of fish and crab trap which is convenient in transportation from place to

place. A particular feature relates to a folding frame on which the netting is applied. This permits the owner of the trap to adequately fold it up until it assumes a compact single one-piece package. The device has few parts, is strong and durable.

STATIONERY APPLIANCE.—E. P. Beckwith, Garrison, N. Y. The object of this invention is to construct an appliance which is more particularly intended to be used in connection with stationery and by means of which it will be possible to almost entirely eradicate creases from papers and particularly from blue prints without in the slightest affecting the same.

HANDLE FOR HANDBAGS.—N. Sloane, 228 Roebling St., Brooklyn, N. Y. The general object of the invention is to provide a handle combining a rigid arm-receiving ring with a flexible element adapted to connect the same in a novel manner with the bag frame so that the two jointly form a handle possessing advantages in the secure carrying and handling of the bag.

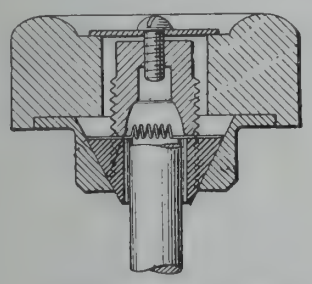
CAN SPOUT.—H. H. Shaw, Cambria, Cal. The invention relates to a device adapted to be inserted in a can, such as an evaporated milk can, by driving into the head thereof to thereby constitute a spout for the pouring of the contents from the can as desired. The device may be driven into the can by pressure or a blow of the hand, thereby obviating the necessity of any tool to deliver the driving blow against the spout.

DRIP WATER SAFE.—J. J. Hickey, 2138 Lexington Ave., New York, N. Y. The invention has particular reference to plumbing apparatus associated particularly with ice boxes, refrigerators or the like for private residences or apartment houses. An object being to provide a device to catch the drip from a refrigerator and direct the same into any suitable drainage pipe or system, and is particularly adapted for use in apartment houses and the like obviating the necessity of a removable drip pan.

WHEEL BEARING FOR FURNITURE.—R. J. Ehlers, Northport, L. I., N. Y. The object of the invention is to provide a wheel bearing more especially designed for use on bassinets, cribs, beds and other pieces of furniture intended to be wheeled about; the said wheel bearing is arranged to permit of quickly mounting the wheels on the piece of furniture without requiring skilled labor and to insure easy running without danger of wabbling or bending. The device is simple and durable in construction.

### Hardware and Tools

VALVE-HANDLE.—W. S. Neil, Minot, No. Dak. The frequency with which valve handles are broken and the fact that valves then cannot be controlled except with a "Stillson"



DETACHABLE VALVE HANDLE

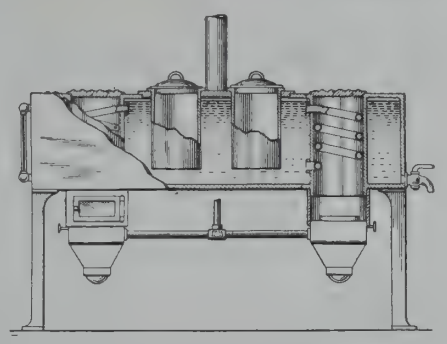
wrench, have led the inventor to provide a valve handle which will fit any size of valve stem and be affixed thereto as a permanent factor, or in case of emergency be quickly detached therefrom and applied to another valve stem of different size.

DRILL AND WIRE GAGE.—R. Ichiba, 136 W. 109th St., c/o C. Gorch, New York, N. Y. An object of the invention is to provide a caliper gage which may be readily applied to twist drills, wire of all kinds, and rods, for calipering the size thereof and for permitting the mechanic to read the drill or wire size directly from the graduated scale of the caliper. A particular object is to provide a precision instrument with a set of lettered size graduations upon one side and a set of numbered graduations on the other.

ADJUSTABLE AND RELEASING GUARD FOR SLICING KNIVES.—C. H. Krapf, 423 3rd St., Brooklyn, N. Y. The object of this invention is to provide an adjustable and releasing guard for a slicing knife arranged to permit the user to cut slices of bread, meat or the like of any devised thickness, and to readily release the slice at the option of the user. Another object is to enable the user to remove the cut slice and deposit it in another place without touching the slice.

### Heating and Lighting

STOVE.—B. H. Dickson and J. E. Frey, Yuma, Col. This stove is adapted to function as a cooking unit and also as an efficient hot-



A CROSS SECTION SHOWING ARRANGEMENT OF THE PARTS

water heater for cooking. The cooking of the food may be started on a dry burner and then be transferred to a receptacle which extends into the hot water reservoir.

HYDROCARBON BURNER.—A. Kaufman, 402 E. 53rd St., New York, N. Y. This invention has special reference to burners for kerosene or the like calculated for the development of an intense heat of a satisfactory and safe nature and with a minimum expenditure of fuel. The important object of the invention is to provide a simple and safe means for generating a maximum amount of heat from kerosene or similar oils relying especially upon the mixture of gasses delivered direct from the oils with a much larger amount of oxygen than is ordinarily experienced.

### Machines and Mechanical Devices

SHEET GUIDE FOR PRINTING PRESSES.—C. F. Huneycutt, Box 965, Charlotte, N. C. An object of the invention is to provide a movable sheet guide particularly adapted for use with bed-and-platen presses of the Gordon type in which the guides will engage with the sheets as they are fed to the platen, influence them to proper positions for impression and leave the impression surface of the platen immediately prior to the act of impression with the sheets maintained in proper position by the gage ordinarily provided.

FLEXIBLE COUPLING.—J. C. Sheler and R. B. Austin, 310 Marble St., Cadillac, Mich. The invention refers more particularly to a shaft coupling provided with a plurality of flexible joints so that power may be transmitted from one shaft to another at different angles. Another object is to provide a coupling which will transmit power at an angle thereto so that the driven shaft will rotate noiselessly, smoothly and without vibration.

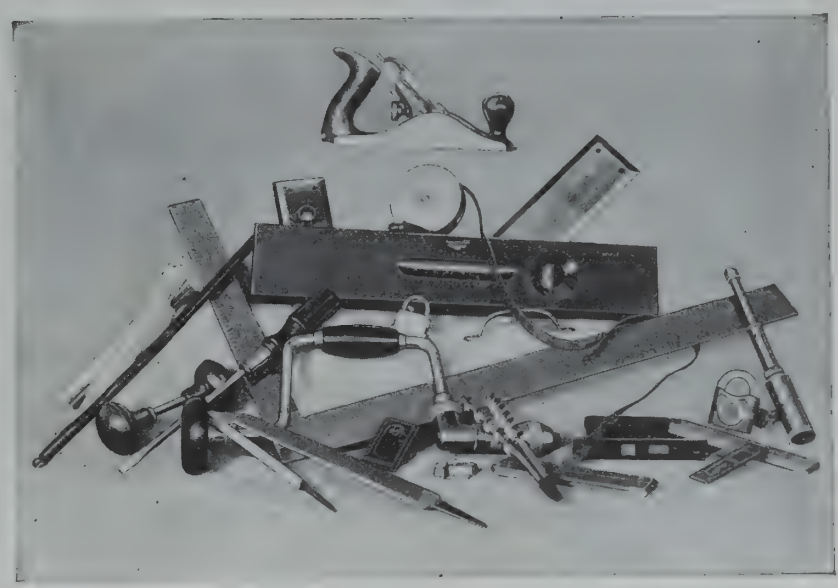
DUPLICATING MACHINE.—H. Cohn, 1060 Madison Ave., Albany, N. Y. This machine is arranged to print at each revolution of the printing drum not only the body of the letter but the heading as well. The heading appears as printed by inked type and the body as printed in imitation of typewritten work.

SHOE SHINING MACHINE.—C. Caldes, 22 Rutgers Ave., Jersey City, N. J. By means of this invention a single attendant in a shoe-shining parlor may operate more than one machine, regulating the machines to stop when the proper amount of brushing or other work is done. The brushes are arranged to move back and forth on the diffeernt parts of the shoe either automatically or under manual control.

PEARL BUTTON MACHINE.—P. F. Dusha and A. Feyk, address Holub-Dusha Co., 1797 1st Ave., New York, N. Y. This machine is particularly adapted for making buttons of the type known as shank buttons and is an improvement on patent No. 1,182,660. Special means are provided for preventing the drill from bending and from breaking or splitting the shanks while they are being drilled.

MACHINE FOR MAKING BUTTER.—J. A. Sheare, The Esplanade, Henley Beach, State of South Australia, Australia. This machine for churning cream into butter comprises a receptacle arranged to revolve in a circular path while at the same time it receives an oscillatin motion. By this means the contents of the receptacle are subjected to a violent agitation and the cream is churned into butter in a very short time.

TAKE UP STOP MOTION.—H. R. Bauer and H. F. Reinhold, 60 Clifton Ave., Clifton, N. J. An object of the invention is to provide a take-up stop motion for power looms, arranged to prevent the formation of a defective fabric by rendering the take-up inoperative and thereby preventing it from advancing the woven fabric in case the filling or weft



# Opportunity Beckons from the Mid-West

ST. LOUIS, one of the largest hardware markets in the United States, needs plants for the manufacture of small hardware, fine tools, machine tools and tool machinery. Most of these products to supply the great St. Louis trade territory must now be bought in the East. The sale of hardware and kindred lines in St. Louis last year was approximately $102,000,000. Much of the raw material is shipped from the Mississippi Valley, manufactured in the East, and the finished product again shipped back to St. Louis.

There is no good reason for this take-it-there-and-bring-it-back haul. A Mid-West factory in St. Louis would have an immense local outlet and could economically distribute in all directions to the markets of the Mississippi Valley, South, Southwest, Middle West and Far West. These hardware lines are a part of the following sixteen industries St. Louis is seeking:

*Shoe laces and findings*
*Cotton spinning and textile mills*
*Dye stuffs*
*Steel and copper wire*
*Machine tools and tool machinery*
*Automobile accessories and parts*
*Drop forge plants*
*Tanneries and leather products*
*Malleable iron castings*
*Farm implements*
*Rubber products*
*Screw machine products*
*Locomotive works*
*Blast furnaces*
*Cork products*
*Small hardware*

A ready market is assured. Splendid opportunities in this field await enterprising men of practical experience and ample capital. You will be interested in the booklet, "St. Louis as a Manufacturing Center." It goes into detail. A letter will bring it. Address

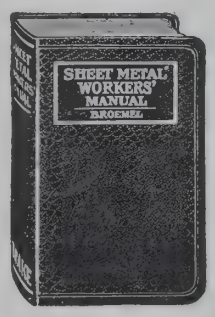
DRAKE'S PRACTICAL MECHANICAL BOOKS

# Just the Information You Want



is readily found in these books. No matter what your line, in our big **FREE** CATALOG you will find a number of books giving exactly the information you want and applying directly on your own work. They will make your work easier and better, and **increase your pay.** Each book is written by a recognized authority in his field, and contains the very latest information and most approved ideas and methods.

Here are a few of the hundreds fully described in our catalog:

SHOP PRACTICE BOOKS

| | |
|---|---|
| Sheet Metal Workers Manual, Leatherette | $2.00 |
| Oxy-Acetylene Welding and Cutting, and Electric and Thermit Welding, Leatherette | 1.75 |
| Sound Welds by the Oxy-Acetylene Method, Cloth | 2.00 |
| Slide Rule, and Logarithmic Tables, Leatherette | 2.00 |
| Handbook for Millwrights, Cloth | 2.00 |
| Machine Shop Practice, Cloth | 2.00 |
| Mechanical Drawing and Machine Design, Cloth | 2.00 |
| Pattern Making, Leatherette | 1.50 |

ELECTRICAL BOOKS

| | |
|---|---|
| Practical Applied Electricity, Leatherette | $2.50 |
| Alternating Current, Leatherette | 1.75 |
| Electric Motor Control Systems, Leatherette | 1.75 |
| Electrical Tables and Data, Leatherette | 1.75 |
| Modern Electrical Construction, Leatherette | 1.75 |
| Electricians' Operating and Testing Manual, Leatherette | 1.75 |
| Electric Motors, D. C. & A. C., Leatherette | 1.75 |
| Electrical Measurements and Meter Testing, Leatherette | 1.75 |
| Wireless Telegraph and Telephont Handbook, Cloth | 1.25 |

AUTO BOOKS

| | |
|---|---|
| Automobile Ignition, Leatherette | $2.00 |
| Automobile Starting and Lighting, Leatherette | 1.75 |
| Starting and Lighting Troubles, Remedies and Repairs, Leatherette | 3.00 |
| Automobile Battery, Care and Repair, Leatherette | 2.00 |

FINGER PRINT BOOK

| | |
|---|---|
| Finger Prints Simplified, Cloth | 2.00 |

ENGINEERING BOOKS

| | |
|---|---|
| Swingle's Handbook for Steam Engineers and Electricians | 3.50 |
| Examination Questions and Answers for Marine and Stationary Engineers | 2.00 |
| Swingle's Catechism of Steam, Gas and Electrical Engineering | 1.50 |

Any books sent prepaid upon receipt of price. Order from this ad. Money back if not satisfied.

These are but a few of the many we publish. Be sure to get our big catalog, sent free.

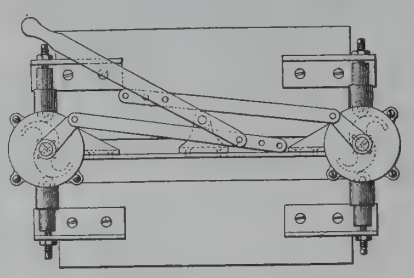
**Drake Books Are For Sale at All Book Stores**

threads breaks or runs out in the shuttle. Another object is to enable the weaver to quickly make necessary repairs and to prevent the restarting of the loom unless the stop motion is first reset.

MOLDING MACHINE.—A. DIEHL, c/o Geo. B. Smith, 407 Bushnell Bldg., Springfield, Ohio. An improvement in molding machines is provided by this invention. A simple me-



IMPROVED MOLDING MACHINE

chanism is employed for simultaneously lifting the cope and the match plate from the drag. The lifting mechanism is operated by a single lever under the control of the operator and the parts are held parallel during the separation.

TEST VALVE.—G. ERNST, 44 Oakland Terrace, Newark, N. J. It is customay in high tension steam boilers to provide a number of test valves in order to determine the accuracy of the water level in the gage glass. As these valves are liable to get out of order, Mr. Ernst has provided a special form of test valve which is claimed to be absolutely dependable.

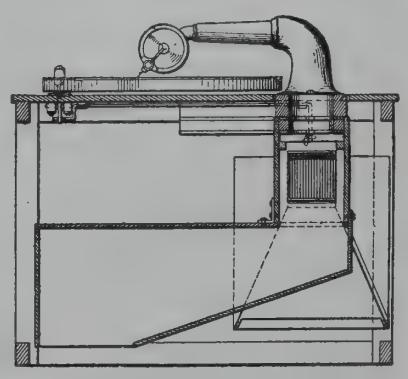
SLUB CATCHER.—F. WEBER, 148 Montana Ave., Union Course, L. I., N. Y. The invention comprises a device designed to prevent the passage of slubs, knots and the like which are formed on thread, cord, yarn, etc., and which prevent the proper passage of the cord through the eye of a needle or through weaving or knitting mechanisms of any sort.

FLEXIBLE COUPLING.—W. L. FRANCKE, New Brunswick, N. J. This invention is an improvement on previous patent No. 1,029,355, granted to Mr. Francke. The coupling is arranged to prevent undue bending of the shims on starting the driven shaft and to maintain the full power of transmission when started. The coupling is housed to prevent extraneous matter from impairing the action of the flexible members.

SEWING MACHINE GAGE.—S. MORGAN and S. HOFFMAN. Address Stanley Gerson, c/o Usona Shirt Co., 801 Broadway, New York, N. Y. In order to facilitate the sewing of buttons on garments, means are provided to do away with the preliminary measuring and marking of the garments. This results in a great saving of time and expense over the previous method of locating the position of the buttons.

### Musical Devices

PHONOGRAPH.—H. GUILBERT, 317 W. Center St., Provo, Utah. The object of the invention is to provide a sound amplifying means which practically eliminates the metallic sounds of the needle on the record and reproduces the finest of tones and sounds. A



A VIEW IN TRANSVERSE SECTION

further object is to provide a phonograph having a sounding board and mounting for the tone arm which is located under and connected to the central portion of the sounding board and which also carries a horn or horns to amplify the sound.

REPEATING DEVICE FOR SOUND REPRODUCING MACHINES.—E. PEREMI, 329 Union St., Brooklyn, N. Y. In connection with phonographs employed for the purpose of teaching a foreign language, this invention provides a means for repeating a particular word, sentence or any small portion of the record whenever desired. The device may be attached to a phonograph without requiring any alteration in the construction of the machine.

### Railways and Their Accessories

PERMUTATION LOCK.—J. P. GERACHTY, 493 Grove St., Jersey City, N. J. This lock is designed particularly for use on railroad car doors, trunks and other devices, and is arranged to allow ready inspection of the car seal with a view of determining whether the lock has been tampered with while the car is in transit.

### Pertaining to Recreation

AMUSEMENT DEVICE.—JACOB IRSCH, 351 Jackson Ave., Long Island City, N. Y. This amusement device is in the nature of a globe bicycle race with both the globe and the bicycle rider moving at a speed in proportion to the speed of movement of the operator. The object is to provide a number of racing figures on bicycles with manually actuated devices for driving them and an automatic disconnecting device for cutting off the driving devices when operated at too high a speed.

### Pertaining to Vehicles

TIRE.—W. H. MCGOWEN, 16 No. 12th St., Vincennes, Ind. The invention has for its object to provide a tire having a resiliency approximating that of a pneumatic tire, without the faults, in that the tire is not subject to blowouts from punctures. The device comprises a filler for tires in the form of an annular hollow support gradually increasing in width from its outer face toward its inner face, a series of arched springs connected with the support and a shoe enclosing the support.

RESILIENT WHEEL.—H. C. ANDERSON, 2461 Fresby Ave., Westchester, N. Y. The invention has for its object the formation of a wheel which possesses all the resilient qualities of a wheel having a pneumatic tire. Another object is to provide what is the equivalent of a pneumatic hub for a wheel whereby the pneumatic cushioning means are so placed and guarded as to be practically indestructible in so far as traction or contact with the ground are concerned.

RESILIENT TIRE.—F. PERDALA, c/o John Soiko, 91 Titchenor Ave., Newark, N. J. The object of this invention is to reduce puncturing of the inner tube to a minimum. The tire is arranged to produce a desired cushionng effect and permt of readily removing a worn out tread from the shoe and replacing it by a new one without requiring removal of the shoe from the wheel rim.

AUTOMOBILE BUMPER.—F. KAMMITTER, 9 Henry St., New York, N. Y. The invention has reference more particularly to an automobile bumper of the flat spring type. An object is to provide a bumper which is secured to the bumper supports by a plurality of spring members so that in case of a breakage of one of the members during a collision the remaining members will still support the bumper and prevent damage to the automobile.

RESILIENT WHEEL.—A. JIMENEZ, 413 W. 156th St., New York, N. Y. The invention contemplates the provision of a wheel in which the movable parts are entirely exposed so that they may be readily cleaned, in which no more oil is required than the usual chassis springs and in which, no matter how caked with mud, or other matter, the parts will always operate positively. The resilient effect is produced by means of apparatus located between the ends of supporting members extending between the axle and the lower part of the rim, and the rim itself.

### Designs

DESIGN FOR A FAN.—C. M. LEVETT, 507 W. 186th St., New York, N. Y.

DESIGN FOR A HEAD RING FOR ELECTRIC LIGHT FIXTURES.—H. SHLAMOWITZ, 3914 12th Ave., Brooklyn, N. Y.

DESIGN FOR A RUBBER SHOE PLATE.—D. H. ELEY and T. H. RYAN, 323 Board of Trade Bldg., Norfolk, Va.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## The Third Degree for the Baseball

(*Continued from page 219*)

standing considerable stretching, these qualifications adapting them for use as baseball covers. The horsehide covers are sewed on the balls when wet and as they dry they shrink and tighten on the balls so that when ready for service they are as tight as the bark on the tree. Fabric covers are not suitable as baseball overcoats because they lack in resiliency, stretching ability and durability.

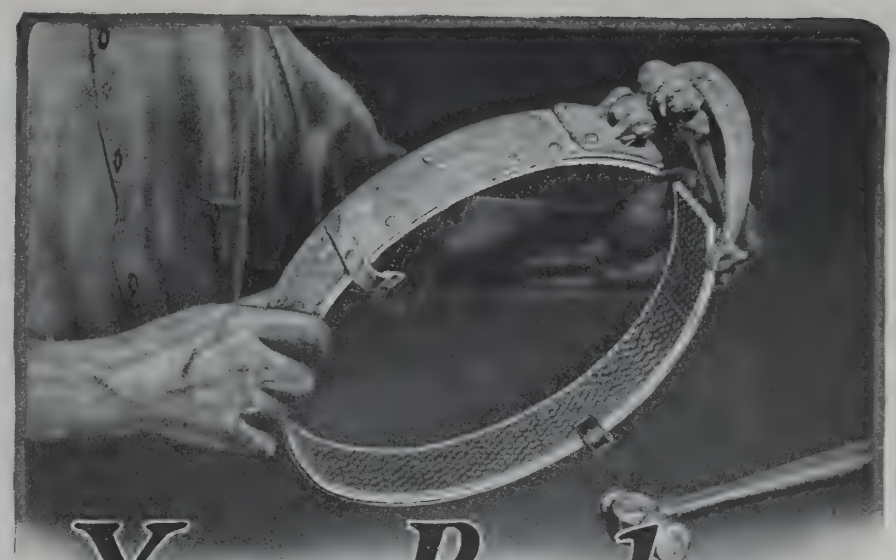
During the war the Government wished to purchase many thousand baseballs for the use of the soldiers both at home and abroad. Six different factories offered samples and bid on these huge contracts. The War Department submitted the matter of selecting the best balls from the samples offered to the National Bureau of Standards which as a result inaugurated the first baseball efficiency tests ever attempted. It was impossible at the time to subject all the baseballs to performance tests on the actual field of play. Hence laboratory methods for the determination of the durability, wearability, adaptability and efficiency of the balls were devised.

All the balls were first subjected to rebound tests to determine their resiliency. Each ball was dropped on a wooden plate from a carefully measured height, the rebound in each instance being accurately measured and the average of five rebounds being accepted as the official test figure for each ball. Subsequently the balls were all run through a tumbler machine similar to that used in foundries to scale the dirt from castings, which subjected the covers of the balls to friction and abrasion test.

A hook 1/16 of an inch in diameter was then slipped under a stitch in each of the ball covers and the force necessary to rip the stitch out of place was ascertained. In all cases it was determined that, invariably, the stitches would break before the leather would tear. Then the double lacings used to sew the cover of the ball were removed and their tensile strength was determined on special machines for that purpose. The leather covers were cut into strips one inch in width and tested for tensile strength and elongation.

Subsequently the ball interiors were thoroughly dissected and the qualities, color and strength of the string and yarns were ascertained while the character of the windings was carefully studied. The best balls were found to have rubber cores surrounded by continuous windings of good quality yarn with a thin layer of cotton thread on the outside of the ball. Some of the inferior balls were wound with only about 50 per cent of good wool while the balance was cheaper material which was not as durable. Most of the balls contained from two to four different windings of woolen yarn. The percentage of wool used ranged from 50 to 83 while the percentage of cotton thread varied from 0 to 21. Some of the balls contained no sizing—a chemical substance like glue or potato starch which is added to the wool and cotton windings to make them sticky. The rubber cores were also subjected to rebound tests while their powers to resist pressure and their compactness were also determined.

When the balls were dropped a distance of five feet the range of rebound varied from 28 to 29.5 inches while where the drop was ten feet, the rebound ran from 48 to 52.5 inches. The composite weights of the balls varied from 140 to 144 grams indicating that the weight corresponded closely in all instances to the official standard. Measured in terms of the different component parts, the weights were distributed in this wise: lacing cord, 1 to 1.6 grams; first winding, 4.8 to 10.3 grams; second winding, 15.5 to 27.8 grams; third winding, 16.5 to 23 grams; fourth winding, 31 to 54 grams; leather cover, 23 to 30 grams; rubber



# Your Brakes
consider how much depends upon them

Safety, property and life depend upon the brakes of any automobile.

Thus, the careful motorist is particular about his brake lining. He takes no chances. He avoids ordinary lining and passes up unknown brands. He buys lining that he knows will meet any emergency.

Raybestos is the original asbestos brake lining. It is especially treated to withstand WEAR. It is guaranteed to WEAR one year.

Complete control in traffic or on the hills follows when *your* brakes are equipped with Raybestos. Avoid substitutes. Look for the Silver Edge.

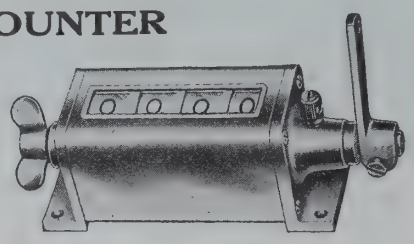
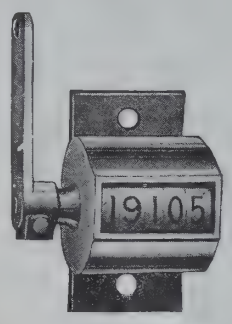
# It'll Cut Costs to Conform

Getting in line for lower price-levels?—Get a reduced labor-cost at machines! Each operative will attend to a larger share of production when the work *registers* as the worker *produces*—on a

**Veeder COUNTER**

*The large Set-Back Revolution Counter at right is ½ actual size. The small Revolution Counter below is shown nearly full size.*





The Set-Back Revolution Counter above records the output of the larger machines where the revolution of a shaft registers an operation. Counts one for each revolution, and sets back to zero from any figure by turning knob once round. Supplied with from four to ten figure-wheels, according to purpose. Price, with four figures. as illustrated, $10.00 (subject to discount).

The Small Revolution Counter at left records the output of smaller machines where a shaft-revolution indicates an operation. Though small, this counter is very durable; its mechanism will stand a very high rate of speed, making it especially adapted to light, fast-running machines. Will subtract if run backward. Price, $2.00.

*Everywhere that conditions stress economy in manufacturing, Veeder Counters can serve—there's a model for every machine. Booklet with complete line free on request.*

**SONNEBORN PRODUCTS**

## If You Will Write Us About Your Concrete Floors

We will tell you how to make them dustproof and wearproof.

Thus you will save money by eliminating repair costs and the expense of bearings and merchandise, which concrete dust ruins in many factories.

**LAPIDOLITH** TRADE MARK

the liquid chemical makes old or new concrete floors harder than granite. It completes the hydration of the Portland Cement and so overcomes the only weak spot in concrete floors.

SONNEBORN PRODUCTS

**Cemcoat**

the durable Mill White. Washable, of exceptional covering capacity. Gloss, Flat and Eggshell, also all colors.

**LIGNOPHOL** FOR WOODEN FLOORS

the modern wood preservative gives new life to old or new wooden floors.

There are over 250,000,000 square feet of concrete floors now in service, which do not dust or wear. Lapidolith has made them complete—perfect.

So write for all the facts and the testimonials of many leading plant owners.

center, 22 to 29 grams; sizing, 0 to 7 grams.

The tensile strength tests showed that the baseballs, in the main, were designed for rough and ready service. The tensile strength of the lacing cord ranged from 27 to 46 pounds per strand as it was pulled from the ball. After the balls were dismembered, the tensile strength of the laces varied from 7.1 to 11.4 pounds per strand. The yarn of the first winding had a strength range of from 0.8 to 3 pounds per strand; that of the second, 0.8 to 4 pounds; the third, 1 to 2.8 pounds and the fourth, 0.95 to 4.4 pounds per strand. The tensile strength of the leather cover varied between 48 and 85.9 pounds per square inch while the stretch of the leather ran from 26.5 to 42 per cent. A 15-ounce load applied to the rubber centers through a disk of the same radius of curvature as the rubber cores resulted in a compressibility of from .003 to .008 of an inch. When dropped 58 inches the rubber cores rebounded distances of from 47 to 48 inches, indicating extreme liveliness and resiliency.

As a result of these tests, the sample balls submitted were divided into three classes. The balls which qualified in the first class were purchased by the War Department and shipped in enormous quantity overseas and to army camps in this country. The efficiency of these balls under actual playing conditions was high and the consensus of evidence indicates that the unique laboratory trials originated by Uncle Sam's experts to determine the comparative value of different makes of balls were extremely efficacious.

### Handling High Voltage with Bare Hands

(*Continued from page 219*)

The safety staging is about 90 per cent wood and has no capacity, so that as soon as the man's body takes its charge, there is no further sensation.

The designer of this ingenious safety staging guarantees satisfactory results up to 110,000 volts and states that this limit will soon be extended. Insulators can be tested and changed and the entire pole top rebuilt, if desired. Switches may be cut in, arms changed, slack cut out, heavy lines tapped; in fact, any job which has ever been done on a 2,300-volt line can now be done on the higher voltages under full load.

A few of the advantages claimed for this new method are: The man is placed in a position where he can work easily and naturally with his hands, which would not be possible otherwise unless the current were turned off. The quality of the work done is equal to or better than that done on a "dead" line with a platform to stand on. The men are said to be far better safeguarded than would be the case in working on lower voltages from the pole, with rubber gloves.

### Muggy Days and Air Thirst

(*Continued from page 220*)

water vapor per unit volume is 4.7 grams, while at the latter there are 9.3 grams present or nearly twice the amount.

To add to our bewilderment a locality may have a lower humidity than another and yet be damper. Who would imagine that on a winter morning Boston with a mean humidity of 73 per cent would yet be drier than Yuma with a humidity of 56 per cent at the corresponding hour? Yet it is so, and the Arizona city has three times the quantity of water vapor present at the Hub.

Always in considering relative humidity the temperature and the prevailing wind must be taken into account.

It would be a great boon to physicians if some reliable index of the air thirst in different localities could be given them; a table of *true* relative humidities, one in which the water vapor present was

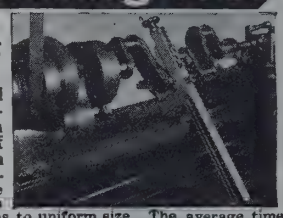
AMERICAN SHEET AND TIN PLATE COMPANY, Pittsburgh, Pa.

**Weber Crank-Pin Re-Turning Tool**

**No Filing**
**No Offsetting**
**No Jigs**



This Weber Tool turns all pins absolutely round from one setting of Crank Shaft, on centers. A micrometer dial enables the operator to gauge his cuts and turn all pins to uniform size. The average time required for trueing up one pin is from 5 to 10 minutes. The 4 pins can easily be finished in 30 minutes, and the entire shaft is completed with only one setting.

**The Weber Tool is guaranteed** to turn crank-pins within as close limits of accuracy as any other known method. It will soon save its cost in any Tractor or Automobile Repair Shop. An assortment of cutting tools are furnished. These will fit the pins of most of the popular automobiles, trucks and tractors. Write for Circular and Prices.

compared with standard values for definite weather conditions.

### Keeping the Human Engine Cool

And as for these muggy days, these days which are the exact opposites of Castilian days, we know that, to quote from an old Spanish proverb "No wise man will argue with his friend" on such a day. For we are all "touchy." We are fretful, not entirely because the day is warm; a succeeding day may be even warmer and the sense of uneasiness less.

The explanation lies in the degree of air thirst. On a muggy day, the thermometer may read 1,112 on the new Absolute Scale, i. e. 87 degrees Fahrenheit. The relative humidity or ratio of vapor pressures is high, say 90 per cent. It is a day when the best humored fat men become somewhat cynical. One perspires freely but the perspiration must be wiped away, for it does not evaporate.

Next day the temperature may be higher, perhaps 1,120, or 91 degrees Fahrenheit but if the relative humidity is 65, due possibly to a light northwest wind, then one is fairly comfortable notwithstanding the added heat. There is actually less water vapor, the amount being 20 grams as against 30 on the muggy day. As we perspire we reduce the skin temperature 22 grads, while on the muggy day we could not cool more than 6 grads. Small wonder that we fan vigorously on muggy days and "fuss" because the fanning is not more effective.
